seriously considered without political or racial prejudice. There are times in our lives when personal interest should be waived for the benefit of the community, and when the efforts of capable men should be supported. It is pretty clear that the continued inability of the directors and administrators to make ends meet should no longer be condemned by the public and by disappointed shareholders, but that our criticisms and suggestions should take the form of continually urging a relaxation of bureaucratic rule. The time is not far distant when Rhodesia will have to be made a public State and not a private property, and amalgamated into a consolidated South African State. It may be five years or more before this happens, and in the meantime, every effort should be made to democratize the government and the conditions under which the white man is governed. The proposition now before shareholders is the creation of 3,000,000 new shares of £1 each to be issued at par. One million are to be offered to shareholders at pro rata forthwith, and subscribers to the new shares will have the option of similarly subscribing for another million on or before March 31, 1910, and a third million up to March 31, 1912. At the present time the nominal capital of the company is £6,000,000, but as many of the shares were issued at substantial premiums, the actual sum subscribed comes to nearly ten million pounds. For instance, in 1895, 500,000 shares were subscribed for at £3 10s. per share. All issues of new shares since the original issue on the formation of the company have been made at some premium, until the issue now being made. Many share-

holders who bought their shares on the open market paid high prices, at one time the quotation being £8. At the present time the shares are quoted at about 15s., so that the motives which will urge shareholders to take up new shares at par will consist of a mixture of duty and self-preservation. It is not possible in the space at my disposal to go into the question of the many reforms contemplated by the Company. One of them, however, may be mentioned. This is the re-organization of the engineering department, whereby the services of Mr. A. H. Ackermann and his staff are placed at the disposal of companies and individuals wanting advice about ores and prospects. The fees charged will vary according to the means of the enquirers. The poor prospector will be charged a merely nominal fee, and a new assay-office is to be established at Bulawayo for this purpose.

Capt. W. R. Thomas, of Tywarnhaile, Cornwall, gave a lecture last week to the students of the Redruth School of Mines on 'Prejudice in Mining.' This was a lecture of a type that should be more often heard in the mining schools, where the personal element and methods of thought are usually passed over in favor of the dry details of every-day practice. It was a lecture that should have been listened to by grown-ups as well as youths. Prejudice in mining is as great a hindrance as indifference in the advancement and improvement of mining and metallurgical methods. In spite of the printing press, electric telegraph, and the railroad, we are apt to be as parochially minded as ever. A Cornishman who has never been out of his county is not receptive to ideas introduced from the outside. An American of local training has a poor opinion of the inventions or devices that come from England. Captain Thomas gave many interesting examples of Cornish prejudice, notably the case when the Cornish managers condemned the Frue vanner and Wilfley table without a hearing. We are all fond of pointing to the Cornishman as slow to move and slow to imbibe new ideas, but my experience has been that the American has just as many preconceived notions. Did not the Americans conclusively prove that the cyanide process was of no value? And how many untraveled American engineers have ever heard of tube-mills, the Merton furnace, or the Elmore vacuum-plant. I heard an eminent American metallurgist the other day condemn the vacuum process before he understood it, adding that the American method of treating ore was to get a profit out of it somehow, not worrying at all about how much was lost. Similarly, there is a popular opinion in America that American companies manage their mines better than English companies do, but any American who has traveled and taken the trouble to study the question knows that this opinion is only a prejudice. Again, in the matter of metallurgical practice, it is commonly supposed that American dressing and smelting is in advance of the rest of the world, but this common supposition is also only a prejudice. I am not writing these remarks just for the pleasure of saying nasty things about my American friends, but for the purpose of pressing home the lesson that prejudice in mining is to be found everywhere.

BUTTE, MONTANA.

Resumption of Work.—Enlargement of Great Falls Smelter. — Cost of Producing Copper. — East Butte. — Electrical Machinery for the North Butte Extension.

All of the properties of the Amalgamated Copper Co. are again in operation. The concentrator at the Washoe smelter at Anaconda was started a week after the mines opened, and the smelter itself is getting into operation again. Within two weeks, it is anticipated, work will be in full swing, producing copper at about the same rate as before the curtailment last September. The output of the Washoe smelter will be from 15,000,000 to 17,000,000 lb. copper per month; that of the plant at Great Falls will also be increased about one-third. A fourth section of the smelter was shut down during the curtailment, and that will be put in commission again shortly, which will mean an additional capacity of about 400 tons of ore daily, making the plant's total capacity 3600 tons. There are other improvements and enlargements under way at the Great Falls smelter that will, when completed, enlarge the capacity about 1000 tons per day, but these improvements will not be completed for a while.

The cost of producing copper in Butte has, during recent years, run from 9 to 12½ c. per lb., the average being about 11 c., this high cost being due to many causes, namely: Extensive permanent improvements and exploration work, charged up to cost of production; ineffieient labor, due to the independence of workmen during the boom days, with its mining litigation and political strife, which made it necessary to give employment to voters, regardless of their capabilities; increase in wages, and increase in the cost of supplies and railroad rates. Many of these causes have been removed. Wages have again been reduced to the normal standard, and miners are giving at least 25% better results than formerly; prospecting work has been stopped, and the permanent improvements have been completed. It is therefore the expectation that copper will be produced henceforth for some time at a cost not to exceed an average of 9 to 10 c. per pound.

The East Butte Co., its officers and lessees, who were recently sued for damages by the South Butte Co., which lays claim to some mineral nnderlying a Great Northern right-of-way that passes over a corner of East Butte ground, has made answer in court and admits the mining complained of, only disputing the value of the ore taken out. The lessees claim they mined it with the consent of the East Butte Co., and the latter says the mining was done under its direction. To emphasize its position, the East Butte Co. has brought an injunction suit against the South Butte Co., and demands an accounting for ore taken out of the same ground. The East Butte has also sued the South Butte for $100,000 damages because the South Butte miners dynamited an important cross-cut from the Adams shaft, into which it broke, while prospecting in East Butte ground. As regards the controversy between the Red Metal Co. and the East Butte lessees, a statement was made in court by an attorney for the Red Metal Co. that the latter had no controversy with the East Butte, and that the damage done by the lessees was nominal. The injunction asked for by the Red Metal Co. against the lessees will not be resisted, and no claim for damages will be pressed. There is the best of understanding between the Red Metal and the East Butte, and also between the latter and the Amalgamated. The engineers of the latter have access to the East Butte mines at any and all times. As the Washoe smelter at Anaconda will again receive custom ore, the East Butte will shortly resume mining.——John A. Ryan, superintendent of the North Butte Extension Co., has gone east to examine electrical machinery, with which the Extension mine will be equipped. The new plant will cost $50,000, and will be installed so that it can be used when the shaft reaches a depth of 1000 ft. The equipment will consist of a double-drum electric hoist, an electric air-compressor, and an electric pump, which will be placed at the 1000-ft. station. An electric pump will also be placed at the 700-ft. station, and will have a capacity to lift 760 gal. per min. The shaft is now down 600 feet.

MEXICO.

Resumption at Velardeña.—San Carlos Copper Co.—Progress in Chihuahua.—The Rosario Co.—Mexican Mines Syndicate.

Most encouraging is the report that comes from Velardeña, Durango, to the effect that, as a result of the recent visit of some of the head officials of the American Smelting & Refining Co. to the company's mines at that point, work will be resumed therein on a larger scale than for some time past. Of the company's properties at Velardeña, the Santa Maria is the only one in which any serious work has been done for the last four or five months, it having continued to yield approximately 12,000 tons per month, most of which, however, goes to the concentrating plant before being smelted. Now, however, work will be resumed at the Copper Queen and the Cobre Grande, and the Terueras will be pushed to its full capacity; and as a consequence the Velardeña smelter will be worked to its full capacity in both the lead and the copper departments. William Davey, superintendent of the mines, will be succeeded by C. H. McMahon, who was for some time in charge of the Sombrerete Mining Co., at Sombrerete, in Zacatecas, but who more recently has been in charge of the A. S. & R. Co.'s Santa Francisca mine at Tepezala, Aguascalientes. As against the good news from Velardeña, comes word that the San Carlos Copper Co., near Linares and just south of Monterrey, in the State of Neuvo Leon, has closed its smelter and San José mines, which Charles Self has kept running for many years, notwithstanding innumerable difficulties. Though this means the laying off of some 500 or 600 men, there has been at all times such a question as to its being a profitable proposition, that the shut-down will be viewed with small regret by mining and smelting men in general. On the properties of the Norias de Baja Mining Co., near Monclova, in Coahuila, considerable development work is going on, principally in the shape of four new shafts which are being sunk on different portions of the ground, and all of which are said to have good showings of lead ore, and for this work bonds for $100,000 are being sold, bearing 1% per month interest, payable quarterly. This company, notwithstanding its many litigations and considerable difficulty with zinc in the ores, has been a steady dividend-payer, and it is believed that the new work will be of direct benefit to its future success. Another property near Monclova, though at present closed because of the low price of copper, is preparing for extensive improvements; this is the Panuco of the Continental Copper Co., a subsidiary of, or closely allied to, the Jimulco, in Coahuila. At the Panuco are large bodies of copper and iron sulphides, running 4 to 5% copper, with a light soft gangue, and experiments have shown that the ore can be cheaply concentrated to 15 or 20% copper, and now S. D. Bridge, one of the directors of the company, states that orders have been placed for a 200-ton concentrator, and preparations are being made to push the construction by A. L. Tuttle, general superintendent for the Continental and the Jimulco companies.

In Chihuahua, the Rosario Mining & Smelting Co. has obtained a concession from the Government for a 30-ton smelter at Urique, in the western part of the State, together with the right to dam and use the water of the Urique river for power purposes for the next ten years. The Rio de Plata Mining Co., for which D. M. Shanks is general manager, has completed its 25-stamp mill, with Pelton wheel-power, in the Guazapares district, and is making regular shipments of concentrate to the El Paso plant of the American Smelting & Refining Co., while the tailing is being stored for treatment in the cyanide vats that are being constructed. The Buenas Aires Mining Co., of California, which is opening up the Lola mine in the Cusihuiriachic district under the direction of W. M. Ford, has also begun shipments of high-grade silicious ore to the A. S. & R. Co. The affairs of the Mexican Mines Syndicate, operating the La Reina and Buenas Aires mines, near Cusihuiriachic, and the Minillas, near Chihuahua, and which went under soon after the recent drop in silver, seem to be still in a muddled condition, but it appears that the Maderos, or in other words, the Torreon Metallurgical Co., being the largest creditors, will obtain control of the properties and either work them until their own claims are satisfied and then turn them over to the next largest creditor, or else work them for the general interest of all the creditors.

Part of Northwestern Mexico.

ROSSLAND, BRITISH COLUMBIA.

General Improvement.—Discovery in the Le Roi.—Shipments From Rossland.—The Boundary District.—Hours of Labor.

Things are brightening up a little at Rossland. A strike of ore running high in gold is reported from the Le Roi mine. The shoot was opened up on the 1650-ft. level, and the assays run from $17 to $40 per ton. This is encouraging, as heretofore the ore on the 1650-ft. level has been poor. The ore is of a pyritic character and where mixed with quartz carries gold, at the same time there is an excess of iron over silica. The Le Roi No. 2 has declared another dividend of two shillings. This company has paid $3.36 per share in dividends since October, 1905. The Blue Bird, Homestake, and Red Eagle properties in the South Belt have been leased and will be actively worked this spring. Three or four other properties in that district will be worked this summer.

While the profit on the Granby operations has almost touched the vanishing point, the company is still working along industriously and breaking former records. The smelter treated 3450 tons of ore

in 24 hr. a week ago, and for the week ended Feb. 29 exeeeded all former records, shipping 22,938 tons from mines to smelter. Total ore shipments for the year to date are 146,947 tons. The Granby pay-roll at the mines is $50.000, and at the smelter $30,000, per month. The mines of the Boundary shipped 29,-423,856 tons of ore during 1907, as against 30,375,-924 tons in 1906. The miners will hereafter work on 8-hr. shifts—from 8 a. m., 4 p. m., and midnight—at the Granby mines, instead of an hour earlier, as heretofore.

The following are the shipments from the eamp for the week ended March 3:

Company.	Tons
Centre Star	3,180
Le Roi	1,249
Le Roi No. 2	77
Evening Star	30
Total	5.229

The Con. Mining & Smelting Co. of Canada has issued a statement to the shareholders covering operations from July to December, 1907. The following were the shipments from their three groups:

	Tons.
Centre Star, Rossland (gold-copper)	87,451
St. Eugene, Moyle (silver-lead)	75,104
Snowshoe, Phœnix (copper-gold)	86,109
Total	248,664

The St. Eugene produced 12,110 tons of silver-lead eoneentrate. The average amount of ore received at the Trail smelter was 1116 tons per day; 42 tons of lead-silver bullion were produeed per day, at $165 per ton; copper matte, 14.8 tons, averaging $453 per ton; pig lead, 38.4 tons daily, at $79 per ton. The gross value of the output for the year approximates $6,000,000, divided as follows: Gold, 39.1; silver, 27.2; copper, 12.4, and lead, 21.3 per eent.

Another shipment of $40 ore has been made from the lower workings of the War Eagle. The ore reeently struek in the Le Roi is of the same character as that in the War Eagle.

SALT LAKE, UTAH.

Smelter Situation.—The Tintic Smelter.—Deep Mining.—Ontario Drainage Adit.

Attorneys representing the interests of the Salt Lake valley farmers, who appeared as plaintiffs in the trial of the late smoke eases, resulting in the injunetion putting the Salt Lake valley eopper smelters out of business, are preparing to make a strong effort to prevent favorable aetion of the Court in granting to the United States Smelting Co. a modified deeree permitting the latter to eontinue operating its lead smelter. This opposition of the farmers to each and every move of the United States company bears a sinister look. There appears to be no doubt about the Ameriean Smelting & Refining Co. having used money to advantage in the eampaign to obtain the end it desired. The executive committee of the farmers was unanimous in granting eoneessions to the A. S. & R. Co. and assisted in obtaining such a modifieation of the deeree as to permit a eontinuanee of operations at the Murray smelter. The United States company has built a bag-house system similar to the one ereeted by its competitor, and in some respects more eomplete; yet the farmers objeet. It is believed, however, that when the hearing on the petition of the United States company comes up on the 30th inst. the latter will make sueh a strong presentation that the application will be granted by Judge Marshall.——The management of the Tintie Smelting Co. is on the alert for ore eontraets, and the output of several of the principal mines of the Tintie distriet has been tied up for a period of five years. Ores will be received after May 1, and it is expeeted that the smelter now under eonstruetion will be ready for operation some time during that month. Being baeked by some of the wealthiest mining men in the State, this Tintie company will beeome a formidable competitor of the older custom smelting concerns in this region. The independent smelter projeet, in whieh the Utah Mine Operators' Association is interested, is said to be moving along favorably; but the projeetors are doing no talking for publication. It is asserted, however, that ground is to be broken before the end of April.

Deep mining in the Tintie distriet has been demonstrated a sueeess. All of the mines opened to 2000-ft. depth show no impairment in the orebodies. In the Mammoth mine, some of the riehest ore ever taken from that property was found at 2200 ft. The Gemini mine has been developed to 1800 ft., and the shaft is being eontinued to 2000 ft. The deepest workings in the eamp are in the Mammoth mine, at 2300 ft.——Unable to market its ores and being unsueeessful in the effort to sell the bonds authorized reeently to raise funds to eontinue development, the Lower Mammoth Mining Co. has stopped all work at its mine in the Tintie district. The eompany last year shipped its produet to the United States smelter at Bingham Junetion under eontraet; but the plant now being elosed, the mining company finds itself without a market.

The direetors of the Daly West Mining Co. have passed the quarterly dividend of $108.000. It is hardly probable that another distribution will be made until the end of the year.——The Ontario mine, at Park City, will be drained within the next sixty days. The water is reeeding at the rate of nearly five feet per day through the drill-holes driven into the main adit from the drift run around what appears to be the last eave. Sinee the first drill-hole was put through, the water has fallen, up to this time, about 160 feet.

TONOPAH, NEVADA.

The Tonopah Co.—Character of Orebody.—The Tonopah Midway.

The Tonopah Mining Co. is operating through three shafts, the Mizpah, Silver Top, and Red Plume. The Mizpah shaft is sunk on the andesite hanging wall of the Mizpah vein; the Silver Top goes down on the Valley View vein, and the Red Plume is in line with the Mizpah and, being eonnected with the others, is used for hoisting waste. The depth of the Mizpah shaft is 900 ft., with levels at 100-ft. stations, beginning with the 200. The vein strikes east-west, both walls being andesite down to the 500 or 600-ft. levels, where intrusions of porphyry and dacite were eneountered. The dip is nearly vertieal between the andesite walls, but takes a considerable dip below where these intrusions eome in. The vein in places is 33 ft. wide, but bodies of porphyry filling are found here and there between the walls, and this filling is not highly mineralized. The solid orebody attains a width of 15 ft. at different points. The gangue is quartz and the preeious metals are present in the ratio of 1 oz. gold to 90 oz. silver. The gold is considered to be mostly in a free state, but in minute particles, while the silver oeeurs as a sulphide and chloride. The iron in the ore does not exeeed 1 to 2%. In the mining operations the entire lode is treated as ore, and in passing to the shipping bins it goes over sorting tables, where about 12% of the whole, consisting of porphyrite waste, is separated. The most extensive development is between the seeond and sixth levels of the Mizpah. The drifts on the seeond level extend 700 ft. eaeh way from the shaft; on the third a drift runs 700 ft. east and 600 ft. west; on the fourth, 1000 ft. east and 600 ft. west;

on the fifth, 1000 ft. east and 800 ft. west; on the sixth, 100 ft. east and 100 ft. west. The workings below the sixth are not extensive.

The Silver Top shaft is 700 ft. deep, with extensive workings disclosing conditions similar to those in the Mizpah. As a general average there is shipped to the mills (at Millers) 350 tons per day from the Mizpah and 150 tons from the Silver Top. Ingersoll-Rand drills are used in the levels and Waugh drills in the stopes. Some of the Murphy drills are also to be tried. Electric power is employed in hoisting and driving the air-compressors. F. A. Keith is general manager, W. H. Blackburn being mine superintendent.

The directors of the Tonopah Midway Mining Co. are H. C. Brougher, J. L. Butler, Henry Anderson, R. P. Stenson, T. L. Oddie, J. J. McQuillan, and W. J. Douglass. The ore shipped during 1907 amounted to 3008 tons, the gross value being $68.51 per ton, while the cost of transportation and treatment was $20.82, leaving a net yield to the mine of $47.68 per ton. The dividends paid within the year amounted to $59,451. Development work aggregated 4088 linear feet. A north cross-cut has been driven 850 ft. from the 835-ft. level, intersecting a vein that is from 14 to 40 ft. wide, on which a drift was run westerly 300 ft., showing ore running from $2 to $17 per ton. At a point on this drift a Vulcan geared hoist was installed for use in sinking a winze in the foot-wall of the vein. This winze is now down 206 ft. and a cross-cut is being made from it through the vein. W. J. Douglass is the company's manager.

Rawhide, Nevada.

RAWHIDE, NEVADA.

The Boom.—Rich Ore.—Exaggerations.

As usual with mining booms, the public mind is unsettled as to what to believe. 'Boomers' and 'knockers' are plentiful, each looking to their individual interests. Statements are made without the least resemblance to truth, "to bite and not to be bitten," being the motto of the fortune-hunter. Even men in responsible positions, who should know better, do harm by wild statements, such as one made by a superintendent here that Balloon hill would produce a billion dollars. This is foolish, indeed, for the deepest shaft is little over 100 ft., less than 50 tons of ore has been shipped, and no returns have been made public; not over 1000 tons of milling ore is on the dumps. Such statements do more harm than good, for the men who know immediately discount even the truth.

The fact is that some streaks of very high-grade ore, assaying thousands of dollars per ton, have been discovered near the surface within a radius of two miles from Balloon hill, some hundreds of sacks of shipping ore are ready for transportation, and some thousand tons of good-grade milling ore are on the dumps. But the value of the ore is only guessed, for those that know prefer to let the 'boosters' place a fancy value on their output. The district will need cheap power to be able to mill the bulk of the ores at a profit. This will come when sufficient ore is developed to warrant the investment in plant and machinery.

The town itself has grown far beyond what the mines warrant at this early date. Every line of business is being overdone. No one should come with less than $5000, either to set up in business or to engage in legitimate mining. The larger part of the work is being done by lessees, and most of these have been unsuccessful; as the town is full of idle men, there will soon be a reaction. The idle men will have to be fed, and the problem may become serious. There is very little money changing hands on deals, and those inside are losing no time in getting out. Whether a slump is feared or money is difficult to obtain, the fact remains that payrolls are small and leases easy to obtain. There is no doubt as to the value of some of the mines, but the boom town is out of proportion to mining development. Goldfield was just the same, at first; it weathered the storm, and we may hope that Rawhide will do as well or better. Those who have endured all the discomforts of tent life on the desert during the winter months, deserve success.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A siphon, theoretically, can lift over 30 ft., but in practice it is unsatisfactory if the lift exceeds 24 feet.

The Sarnia tunnel, on the Grand Trunk railway system, is being equipped with an a. c. single-phase locomotive. A 1000-ton train will be hauled 19,000 ft. in 15 minutes.

Mine timbers should be cut before the sap rises in the trees. The winter is the best time to cut a supply of timber, and this should be well seasoned before use. It is then lighter to handle and easier to frame.

The flow of water in a pipe is proportional to the square root of the fifth power of its diameter, other things being equal. Thus it requires 32 pipes of 3 in. diam. to carry the same flow as one pipe of 12 in. diameter.

Electric energy is measured by the product of the power and the time. The practical units are the joule, which is equal to one watt second, and the kilowatt-hour, which is equal to 2,655,000 ft. lb. or 1.34 hp. hour.

Electric power is the rate at which energy is being transformed in a circuit. It is expressed by the product of the instantaneous values of electro-motive force and current in the circuit. The practical unit is the kilowatt.

A kelvin is a name that has been suggested for the kilowatt-hour unit. A less cumbersome name than that in general use is required, and the adoption of this proposed word would be a suitable recognition of a great electrical engineer.

Greenstone is a general name for igneous rocks that are fine-grained and dark green in color. It is used when closer determination, with the microscope, is impracticable. Most of the so-called 'greenstones' are diabase or diorite.

Amygdaloid is a term applied to cellular lavas, full of almond-shaped holes, which were filled with steam at the time of consolidation and are subsequently filled with secondary minerals, as is the case in the copper-bearing rock of Lake Superior.

The amount of copper ore treated in the United States in 1906 was 20,000,000 tons, averaging 2.15% copper. The ore from the western States contained 3.65% copper and $1.70 in gold and silver. The average price of copper was 20 c. per pound.

All the coal in California is lignitic or sub-bituminous in character. There are a number of coal areas, the chief of them being the Monte Diablo and Corral Hollow fields, in Alameda and Contra Costa counties. Small quantities have been mined for local use in several other counties.

In the Tintic district, Utah, there is a good example of the enrichment of ores in the oxidized zone. The ores contained in the sedimentary rocks in this district are completely oxidized to a depth of several hundred feet, and partially to the lowest points reached in the mine workings.

Asbestos is the commercial name given to two types of fibrous mineral: one of them is actinolite or tremolite, a fibrous amphibole; the other is a fibrous variety of serpentine, known as chrysotile. Asbestos means non-combustible and the term stands for mineral fibre that resists both heat and acid.

Replacement deposits occur in difficultly soluble rocks like quartzite and granite. The formation of gold-bearing quartz veins in zones of crushing in schist, as in New Zealand, and the replacement of granitic rocks and andesites to form lead deposits in the Cascade range in Washington, are notable examples.

The uses of asbestos are constantly increasing. Of the two varieties, the chrysotile is the more valuable, especially for products involving spinning. It is spun into yarn for packing and cloth for theatre curtains. The amphibole variety of asbestos is used in the manufacture of boiler lagging, steam-pipe covering, and insulating cements. All of these uses depend on its slow conduction of heat and electricity.

Quicksilver ores are reduced by volatilization and condensation. Retort reduction is essentially a simple distillation, in which the mercury vapor is kept separate from the flame and smoke of the fire-box, while in furnace reduction all the gases enter the condenser together. In California both retorts and furnaces are employed, more than half a dozen 50-ton Scott furnaces being in use. At the Black Butte mine in Oregon a new type of furnace has recently been built, designed to treat a large tonnage of low-grade ore.

The auriferous gravels of the Sierra Nevada represent Tertiary streams which had entirely different valleys from those of the present day. Maps showing the Tertiary topography have been made by geologists, and it is seen that the present valleys are deeper, and the streams of the present day are generally at right angles to the former ones. After th old auriferous gravels were laid down, great flows of volcanic rock filled up the valleys, and as tilting occurred at the same time, the new streams followed independent courses. They have now cut down their beds so as to expose the Tertiary gravels at many points.

Amalgamation is not used in tube-mills, as this method of grinding is used for re-grinding prior to cyanidation. Amalgamation in barrels is, however, used for cleaning up battery and blanket sands. The use of mercury in barrels or tube-mills, where stones or iron are used for grinding, is not economical, owing to the flouring and subsequent sickening of the mercury which is sure to occur. If it is used, the barrels should be revolved slowly, from 12 to 16 rev. per min., and the operation continued from 8 to 24 hr. Grinding with mercury cannot be recommended in general practice, owing to the high loss of quicksilver.

Drill steel is often found to fail when hard rock is to be drilled. The loss of time from this cause is often a serious matter. The usual cause is that the steel is of inferior quality, and it pays to purchase the best on the market, and to pay wages sufficient to keep a good drill-sharpener. With good steel sharpened and tempered carefully, no serious difficulty should occur. Garnet and pyrite are the toughest minerals to drill, but by sharpening the drills with a wide bevel on the edge and carefully gauging the bits, no difficulty should be encountered. If the drill steel has been burned by inexperienced tool-sharpeners, it must be cut off, as it will be impossible to make this steel take a temper.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Mining Law Reformation.

The Editor:

Sir—It is time public opinion should be educated on reforms necessary in the mining laws and customs of this country, and this can be done in no better way than by starting a discussion of the subject in the MINING AND SCIENTIFIC PRESS; and, although such a movement would be best started by yourself, still, as the time is ripe, and you have not done it, I beg permission to submit a few rambling thoughts on the subject, with the hope that it may bring out others more deserving of notice, from the many men interested in the welfare of the country, so that, from the many suggestions, enough may be gathered to form the nucleus of a sane, adequate, and just mining law for our great country.

The present apex law is an absurdity, and unworthy of a progressive intelligent nation. However, it exists and must be recognized. A new law should be enacted fixing a square of some size, say, 500 ft., as a unit for all mining claims, and any locator should be allowed to take up as many units in one claim as he might desire or deem necessary.

In order to make the new law effective, the present mining laws and customs should be abrogated, and the Federal government proclaim a separation of surface-land right, and the sub-surface mineral deposits; defining surface rights to mean the land which the Government will cede to locators for agricultural or ranching purposes, transferring same as per existing laws, but reserving all rights to sub-surface mineral deposits, such as lodes of gold, silver, lead, mercury, and coal, in fact, all metals and minerals except iron and the salts, these last to belong to the owner of the surface rights.

A tax should be placed on each unit of a mining claim to be paid yearly, not as a revenue, but as a guarantee of good faith on the part of the locator, and as a means to prevent two or three locators from hogging a district to the exclusion of all others, and to the detriment of the future development of that district, which would mean a loss to the public and to the country, due to the non-development of same. Once a location were made, a patent should be issued for it within a year, and the land charged for at some specific rate per unit, say, $25, exclusive of the customary fees for patenting mining claims.

As the new law could not be made retro-active, the present law must be observed in all locations prior to promulgation of the new law. These locations should be recognized and left to take their chances before the courts as heretofore, where difficulties occur; however, it should be left optional with the owners of such claims to come in under the new law; in other words, to re-locate, where there is free ground, and where not, to voluntarily accept all boundary lines as vertical planes, as they would be considered under the new law. If possible, where lines could not be accepted as vertical planes, difficulties should be avoided under the old law, by recognizing the right of the first location, where there was conflict due to two veins running into each other, however insignificant the vein in the first location might be, if it were unbroken and persistent in depth. All lands sold prior to the promulgation of the new law would of course retain all the rights acquired with them, and the new law would only apply to the existing Government lands. All surface rights necessary for legitimate mining purposes, where needed by the mine operator for carrying on his work, should be guaranteed by law by expropriation, at a price not in excess of the current local value of the land, where such surface rights are owned by a citizen, and acquired by same after promulgation of the new mining law. Lands acquired by private citizens prior to the new law would have to be arranged for, if needed for mining purposes by the mine worker, in accord with the requirements of the present laws effecting such deals.

As human nature is rather inclined to be conservative, some exception may be taken to the unit suggested, and it may be asked how this unit would be effective in making locations. To this can be answered that it would be favorable in all cases, as will be seen from the following examples: On small lodes, or those having short ore-shoots, 500 ft. square would amply cover the valuable part of the ground to 500 ft. in depth on veins of ordinary dip. Should the dip be steep, and the vein run on the surface for a thousand feet, two claims along the strike could be taken, having the foot-wall side-line located 10 to 50 ft., or more, from foot-wall of the vein, at the option of the locator.

Should the dip be at an angle of 30°, two units could be taken on the dip, making a claim of two units long by two units wide, or 1000 by 1000 ft., a very respectable claim and one that would cover the valuable ground along any ordinary lode.

Where a vein is flat, the dip can be covered by three units; and on an ordinary vein, with such a dip, the claim would be 500, 1000, or 1500 ft. along the strike, according to its persistence on the surface, and 1500 ft. with the dip, thus covering effectively the surface indications to a reasonable depth.

If difficulties are to be avoided, and if chances for litigation are to be reduced to a minimum, and millions of dollars saved to the mine workers and investors, the necessity of some such law must be admitted. Some may say, "Why bother? We have gone too far already along the old lines; let us let bad enough alone." These can be informed that the mining industry of the country, huge as it is, is but in its infancy; and besides, it is never too late to mend. Then, let us mend.

Electrical Hoisting.

The Editor:

Sir—A few notes on the electric hoist recently installed at the Bunker Hill mine, in Amador county, California, may prove of interest to the readers of the MINING AND SCIENTIFIC PRESS. I need not remark on the excellent workmanship of the piece of machinery nor its masterly installation. The hoist is a double-reel double-geared machine; the heads of the reels are 8 ft. diam., the gear-wheels are 9 ft. with 10-in. faces, the inside heads being bolted to the driving gears. The outside heads have a projection for lowering brakes. The two reel-shafts are 7⅞ in. diam. at the centres and the ends turned down to 7 in. to pass into the bearing-boxes. The pinion shaft is 6 in. diam., resting in three boxes projecting at one end for a spur gear which is driven by the pinions of the electric motor. The clutches are of the sliding jaw type. The machine is planned to hoist 3 tons of ore 3000 ft. The electric driver is a 16-pole, 150-hp., 60-cycle, 3-phase, 550-volt, variable speed induction motor, the full load speed being 430 rev. per minute.

A working test for the past sixty days has fully

demonstrated the surprising efficiency of this electric plant as compared to steam, even as regards perfect control and handling by the operator. The old steam hoist generated its power from fuel-oil; the average fuel expense during one year amounted to $440 per month, while the electric hoist cost $189 (or 42 hp. at approximately $4.50 per hp. per month of 30 days); in each instance an average of 3000 tons of ore per month was lifted an average of 1200 ft.; a net saving of 8⅓ cents per ton of ore hoisted.

The following tables are averages of the actual horse-power used in hoisting 1½ tons of ore 1600 ft., both with and without counter-balances. The skips when empty weigh approximately 1500 lb. each, and the cable 2 lb. per ft.; the shaft is a 60° incline.

Mining in Rhodesia.

The Editor:

Sir—In the last issue of the Press, your London correspondent states that "there is another reason why the population does not increase in Rhodesia, namely, the opposition of the present settlers to the dumping of criminals and ne'er-do-weels in their midst."

Surely your correspondent does not know his Rhodesia when he makes such a statement, for, during a prolonged residence in that country, I never heard of that point ever being raised. As a matter of fact, Rhodesia has never been a dumping ground for either of the above classes, and only such as would naturally come to a new mining country have found their way there. It may be that the absence of any marvelously rich camps, like Coolgardie, Tonopah, or Goldfield, and the lack of any great gold rushes, did not make the country sufficiently attractive for the lawless class; but, be that as it may, the fact remains that Rhodesia has probably one of the most law-abiding populations of any mining country in the world, and moreover, labor-unions are an unknown quantity there.

So far as the criminal class is concerned, the absence of crime in Rhodesia (and also at Johannesburg in the ante-bellum days) has been most remarkable. Highwaymen and murderers are almost unknown, while the tin-horn gambler, with his faro lay-out and his three-card-monte game, has scarcely ever been seen in the country. To those of us who have been familiar with the lawless condition of affairs which generally prevailed at such places as Leadville, Tombstone, and similar mining camps, where the six-shooter was the usual Court of Appeal and where the holding-up of the stage-coach was an easy method of recouping fallen fortunes, the entire immunity from these conditions has been a great surprise, and it certainly speaks well for the law-abiding nature of the ordinary Briton. The general freedom from crime in the Rand in early days made people careless, as they felt so secure, and I have frequently carried several thousand pounds sterling (for my pay-rolls) in an open buggy across 10 miles of lonely veldt, without any other protection than a revolver, and never thought anything of it.

Rhodesia has been producing gold bullion for the past ten years and, to my certain knowledge, there has only been one bullion hold-up (that of a private conveyance) during the entire decade. Before the extension of the railway north of Bulawayo, it was customary to send all the bullion by stage-coach from the different mines to either Bulawayo or Salisbury, and scarcely ordinary precautions were taken to safeguard it. The bullion would generally be put in the boot of the stage, in care of the driver, who did not even carry a shotgun, and a hold-up would have been the easiest thing in the world. The carrying of the bullion, in fact, was very casual, as the following amusing incident will illustrate: During one rainy season, the stage carrying the bullion from a well-known mine, got mired in vlei, or swamp, along the road, and it was necessary to unload the stage completely before it could be pulled out. During the process, the bullion was placed against the trunk of a tree on high ground for safe-keeping, and it was not until the stage had reached a station 40 miles away that the driver discovered that his bullion was one bar short! In the meantime an Italian, traveling in the opposite direction, happened to find the missing bar and reported his discovery to the officials at the nearest town; he was promptly put under arrest, despite his protests, for stealing the bullion, and it was only after the real facts became known that he was released.

There has always been a certain amount of amalgam stealing, and doubtless high-grading takes place at the richer mines, but this is common to every mining country, and we need not go far from home to meet with these conditions.

From the foregoing, it is difficult to understand how your correspondent could possibly make a "comparison with Western America." As far as the prosperity of the country is concerned, Sir George Farrar, one of the leading mine operators of Johannesburg, is quite enthusiastic over the mining outlook in Rhodesia, and he has invested a good deal of money there. While only a few of the large mining companies are paying dividends, the tributor and lessee, who is contributing one-third of the total gold output, or nearly 20,000 oz. monthly, is doing well, and the country is sharing in his prosperity.

RECENT VOLCANIC ERUPTIONS IN BERING SEA.

Written for the MINING AND SCIENTIFIC PRESS
By ARTHUR S. EAKLE.

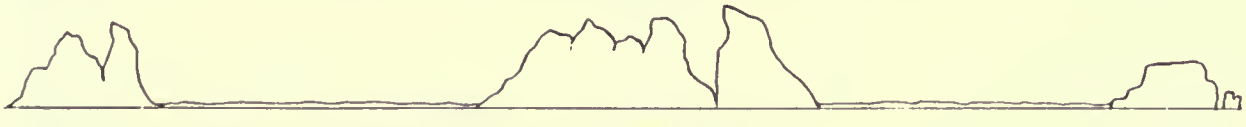
A report comes to us from Nome, Alaska, that a shower of ashes fell in that vicinity on the 26th and 27th of last November, which covered the snow with a layer of black dust, one-fourth of an inch thick, near Nome, and the layer was said to increase in thickness toward the north. Many square miles of territory are known to have been covered by the shower. Some of this ash was scraped from the ice of Bering Sea and sent to the MINING AND SCIENTIFIC PRESS by a reader for examination.

The ash appears as a dark brown, almost black, powder, and under the microscope is seen to consist wholly of minute particles of dark-brown volcanic glass. It has evidently been formed by the violent explosion of an obsidian cone or mountain, and, judging from its finely powdered condition, it has probably been transported a long distance from the seat of eruption by the winds, perhaps from the Siberian coast, as the wind was blowing from that direction at the time.

Volcanic activity is still manifested among the islands of Bering Sea. The long chain of the Aleutian Islands, stretching westward in a curve for a distance of nearly 1000 miles from the Alaska peninsula, contains several volcanoes still showing signs of activity and others now dormant or extinct, which have been active in recent years. Last summer Akutan was sending up intermittently a huge column of vapor, which spread out above into the well known cauliflower or umbrella shape, similar to the smoke column that hung over San Francisco during the recent conflagration. Mt. Makushin on Unalaska and Korovinski on Atka island had their high snow-clad summits almost constantly enveloped by dense clouds of vapor, arising from their craters.

One of the best illustrations of the formation and destruction of land by volcanic eruption is seen in the history of Bogosloff island, which rises in the Bering Sea, about 50 miles northwest of Unalaska island. In 1776 Ship Rock was observed and in 1796 Castle Rock or Bogosloff was thrown up. Nearly a century later, about 1884, Fire island arose, distant about one mile from Castle Rock. In 1891 Ship Rock was destroyed by an eruption, leaving Castle Rock and Fire island as two peaks, separated by a wide and deep channel. In May, 1906, the *Albatross* reported a new cone midway between these two islands, which received the name Metcalf cone. The revenue cutter *Perry* visited the island in July of that year and the name Perry peak was given to this new cone without knowledge of its prior name. Metcalf peak was still separate from Castle Rock by a channel, seven fathoms deep, but was connected with Fire island by a narrow isthmus a few feet above the sea. Last summer in July, just a year later, a new cone was found to have arisen 450 ft. high, from the base of Metcalf on its south side. It had been formed partly from uplift and partly by the splitting asunder of Metcalf cone. It was observed first by the cutter *McCulloch* and received the name McCulloch peak. The former channel between Metcalf cone and Castle Rock became filled and the land raised and extended by this eruption, so what appeared formerly as separate islands became one island about 1½ miles long and ¼ mile wide. This island can properly be called Bogosloff.

On the seventh day of last August, the writer spent about four hours on Bogosloff island, collecting rocks for a future report. Castle Rock had long since become cold; Fire island had lost its fire, and its surface was cold and no steam issued from its crevices; Metcalf and McCulloch peaks were hot, steam and sulphur vapors poured out from the many crevices on the sides and sulphur was depositing as yellow patches in the cooler places. A lagoon of boiling salt water colored yellow by sulphur partly surrounded McCulloch peak. Hornblende-andesite, basalt, basaltic agglomerate, and pumice formed the make-up of these peaks. Some of the rock boulders contained much disseminated pyrite. The island was inhabited by countless thousands of gulls and puffins, which had made their nests on Castle Rock and Fire island, and by hundreds of sea-lions. On September 1, three weeks after the writer chipped rocks from the hot sides of these peaks, McCulloch peak exploded and ashes fell in the town of Unalaska, 60 miles distant. The entire aspect of the island became changed by this volcanic outburst. The position of McCulloch peak is now occupied by a lagoon, great quantities of débris have covered the other peaks, the connecting land has been raised, and the island is penetrated by several lagoons. The dust which fell from this explosion is a gray pumiceous ash, containing an occasional crystal of hornblende. It is evidently finely shattered hornblende-andesite.



The Peaks of Bogosloff Island From the Coast Side, as Seen on August 7, 1907.

At the beginning of July, 1907, the 1500-kg. Heroult electric furnace employed at Lindenberg's steel works in Remscheid, Germany, turned out its 2000th charge. It had been at work continuously since March, 1906, treating a charge previously melted in a Siemens-Martin metallurgical furnace. The dolomite bed of the Heroult furnace was repaired after every charge, and a new cover made of silicious material was required every three to seven weeks; in other respects the furnace lasted well.

CRUSHING ORE.

Written for the MINING AND SCIENTIFIC PRESS
By M. P. BOSS.

*A true seeker of knowledge is not content to know of a fact without knowing why it is a fact and to be able to fully analyze it. To an engineer and expert capable of intelligently analyzing a matter or condition, the bare knowledge of a fact seems not fully conclusive, without the application of the test of enlightened reasoning, and to him, capability to analyze correctly, counts for more than a bundle of information supposedly correct. The latter may be bought in books, for a dollar or two, while the former is the judgment and personality of the man and is transferable only by reflection. It is the object in the following pages to elucidate some fundamental principles, as the writer has found them, and to put the student mind into a train of analytic reasoning, upon the subject in hand. There has been and is such a multiplicity of devices to make coarse ore fine, that it would be a great undertaking to treat the subject exhaustively, and such is not the object of this essay.

Ores and rock for commercial purposes, taken from the earth, are crushed to a degree of fineness suitable to requirements, which may be as coarse as several inches in diameter or it may be too fine for measurement. An example of extreme fineness may be seen in water that is slightly discolored by earthy matter after having been for some time in repose. Each piece or particle so crushed represents fracture or cleavage to the extent of its superficial area. Rock fractures are irregular and particles resulting from fracturing are variable in size. They can be measured with only approximating correctness by passing them through apertures of a specific size A, followed by passing over apertures of smaller size B, and the product that does not pass B may be described as passing A but not passing B. But even this approximation is subject to variation with different types of crushing. The product from some crushing may be slivered and angular, while from other methods of crushing it may be worn and rounded. The sum of areas of fracture in an accumulation of crushed particles is not computable, but to give to the mind some approximating conception we may assume that a cubic inch of quartz (or other substance) is fractured into true and equal cubes 0.002 inch in diameter. This would represent an area of fracture or cleavage of 1500 square inches, minus six square inches (the superficial area of the one cubic inch) or 1494 sq. in. actual fracture. A cubic foot thus divided would represent 17,994 sq. ft. of fracture or cleavage area, and 13 sq. ft. of fracture, or approximately one ton, would represent an area of 233,967 sq. ft. of cleavage.

Fracture that is effected mechanically represents a consumption of power proportionate to the hardness and toughness of the material, plus the loss in the mechanical application. In all power applied mechanically there is necessarily a loss in friction of the mechanism, and in power applied to crushing ore there is also a loss in its application to the rock being crushed. Wear of parts in contact with the rock represents a part of this loss. There may be a serious loss of power within the mass of material being crushed, by friction and by compression, that is ineffectual in crushing.

Ore is crushed by compression between two crushing members; by grinding between two crushing members; or by impact against a crushing member. A crushing device to be effective must not only have power applied economically to the crushing proper, but it must systematically and properly supply fresh material to the crushing and as systematically discharge the material when sufficiently crushed. Hence we may, for convenience and analysis, segregate the crushing of ore, as popularly considered, into three stages, thus: Supply, getting the material into the crushing field; fracturing, or the act of actual crushing; and discharge, getting the properly crushed material away from the crushing field. Errors of design for crushing are less conspicuous to the ordinary observer in the first and third stages than in fracturing. Crushing devices may be continuous in action upon a material or they may be periodic. Crushing devices of periodic action may be cumulative of power during the non-crushing moment, or they may be non-cumulative. Chilean mills, rolls, barrels, and disc grinders are examples of continuous action. Stamps accumulate power while they are being raised, all of which, less the friction involved, is expended at the moment of arrest from fall. Jaw and gyratory crushers are periodic in action and non-cumulative, except in the equalizing effect of the fly-wheel.

Crushing between two members may be classified: 1. Faces parallel and reciprocal in action, exemplified by the stamp. 2. Faces parallel and non-reciprocal, as exemplified by grinding pans and disc grinders. 3. Two vertical and more or less diverging plane surfaces, with reciprocal action, exemplified by jaw-crushers. 4. A circular member, with internal face, within which operates a smaller circular member with external face, the axis of which is a revolving incline, popularly called gyratory. 5. A plane surface over which passes a cylindrical one, having a horizontal axis, exemplified by the Chilean mill. 6. Two cylindrical external surfaces with horizontal axes, exemplified by rolls. 7. A cylindrical internal surface, the axis of which is vertical, within which revolves a smaller cylindrical external surface of vertical or nearly vertical axis, exemplified by the Huntington and Griffin types of mill. 8. A cylindrical internal surface, the axis of which is horizontal, within which revolves a smaller cylindrical external surface of horizontal axis.

These several types of crushing between two members have many modifications, some of which do not come within the foregoing description, as, for instance, the Chilean mill sometimes is built with rollers inclined inward, to neutralize the centrifugal energy, in which case the ring-die is properly coned, to give parallel faces to the two members. Another instance is what might be termed a modification of

*Copyrighted, 1908, by the MINING AND SCIENTIFIC PRESS for the author.

the grinding pan, substituting a crushing aetion for that of grinding, by making the muller mildly conical, the axis of whieh, in operation, is a revolving ineline. Crushing by impact against a crushing member is effeeted: 1st, by hurling it from a rapidly revolving meehanism; 2nd, hurling it by eompressed air or steam; 3rd, by dropping it from a height.

Wear of crushing members in action is necessarily constant, but is variable in degree, the chief modifying factors being the quality of the metal of which they are made, the angle of pressure on the surface

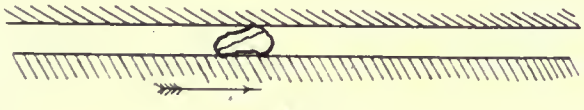


Fig. 1.

An enlarged section, showing a particle of ore between two grinding discs, and how it may be fractured, when caught by slightly penetrating the grinding surface.

and the distribution and movement of the material being aeted upon. Crushing members that reciprocate and have faces that are parallel or faces that do not greatly diverge at point of pressure should have extreme hardness as their predominating quality, whereas, faces that are parallel and have a grinding action, or faces that have a wide angle of divergenee, toughness shonld be the predominating quality. A stamp falling directly upon broken ore has chiefly to withstand direct penetration, but a grinder consisting of two parallel discs, pressing axially together, one of which revolves, or the two revolve in opposite directions, have an effect upon grains of material to disintegrate them in two ways: 1st, to wear them away by rubbing over their surfaces; 2nd, to fracture them by detrusive* resistanee.

If the discs are of glassy hardness they will glide over the particles, but if they are less hard and have a quality of toughness, the grains will penetrate the surfaces enough to become caught and ruptured. In the former ease the discs will wear proportionately more than in the latter, while the effeetiveness in crushing will be less.

Crushing by reeiprocal action between two parallel faces results in minimum wear of crushing members, unless modified by conditions. Detrusion of crushing members increases with angle of divergence. Angle of divergenee of pressure in a crush-

Section showing faces of stamp-shoe and die, approximately as worn under favorable conditions and with close fitting guides.

crushing members will have varying effects, as modified by conditions. If an individual piece contacts two crushing surfaces in line with their approachment, and if the approachment is at right angles with the surfaces, the crushing is accomplished with maximum efficieney, there being minimum friction and less of power. If the component pieces of a bed of material have less diameter than the thickness of the bed the wedging effect of particles between particles diverts a part of the force in a lateral direction. If the power of compression is sufficient to crush in this diverted lateral direction, it is effi-

*'Detrusion' is the act of thrusting or driving down. Editor.

cient, but if the bed of material is so thick that the diverted lateral pressure does not crush, the force thus diverted is absorbed and lost.

A stamp-shoe compressing upon a die, compresses with greatest force at its centre, there being lateral relief at its periphery. If the surface of the die is lower than the discharge, material banks about it, more or less, and there is no detrusion on the periphery below its working face. A shoe in falling is exposed to the attrition at its periphery of pieces lying partly within its path and by particles being expelled by the lateral diverted force of compression. This results in detrusion of the periphery of the shoe beyond its face.

When a stamp operates in an approximately true path, as with iron guides, compensation for this peripheral wear should be given by making the die smaller in diameter than the shoe.

A stamp-shoe that is operated upon a thin working layer of material over the die wears to a face somewhat concave with a slightly rounded edge at the periphery.

A stamp-shoe that is operated upon a thick layer of material over the die wears to a convex face with well rounded edge at the periphery. The cause for the first is due to there being but little outwardly expelled material at the shoe contact and the wear being chiefly proportionate to degree of compression, which is greatest at the centre and has lateral relief near the periphery. The cause for a convex face on a stamp-shoe is that in operating upon a thick bed, expulsion of material is confined and restricted and practically equalizes the degree of compression over the bed operated upon and as attrition is greatest away from the centre, the shoe is most worn at and toward its periphery.

While a stamp-shoe and die have been cited as having crushing surfaces parallel, and being practically so when new, in wear they become only approximately parallel. Reasons have been given for the wearing of the face of the shoe away from a straight line and also why the periphery of a die does not wear below its surface. The face of a die under ordinarily good conditions wears declining from the centre to its lowest point a little away from its periphery toward which it gently inclines upward.

Wear on the face of a die is mostly by attrition from the forcing outward over its face, the material under pressure from the effect of the blow of the stamp. The outward movement is least at the centre, but increases toward the periphery, but as the pressure is relieved at that point the detrusion is lessened.

There are idiosyncrasies of wear of crushing members. Deep pockets sometimes wear in dies. The primary cause for these may be a soft spot or a blow-hole, but once started they are increased and deepened by attrition from lateral movement of particles under pressure, by coarser pieces over the depression being forced downward by the blow of the stamp.

The first stage of crushing, that of introducing into the crushing field the material to be crushed, applies not alone to the fresh material but to the reintroduction, or distribution, of material already in process of being crushed. Jaw and gyratory crushers, rolls and disc grinders, that are not grinding pans, act only upon freshly introduced material, which falls away after it has passed the crushing zone. Chilean mills crush only the material that settles upon the path of the rollers and all freshly introduced material as well as all that is insufficiently crushed must continue to lodge upon that path after each passage of the roller, an action that involves some period of time, and limits the efficient speed of the mill. Roller-mills having vertical axes and which crush by centrifugal energy, operate upon material that is thrown against the path of the rollers by the operation of the mill, for which, time is an element for efficiency, as a roller following its predecessor too quickly will pass before the material has found firm lodgment against the vertical path, or on the other hand, if the roller follows too tardily, the lodgment is at its ebb.

Grinding pans, having two horizontal faces, one of which revolves, operate submerged in a material, from which it feeds without discrimination, and into which it discharges its finished product.

Individual stamps are fed by gravity and rush of semi-liquid material to fill vacancy left by upward moving shoe, and from which place it is in turn violently expelled by the return drop of the stamp. Stamps grouped in mortars are fed by splash from other stamps, as well as by back flow.

A device that is best adopted for coarse crushing is not well adapted to fine crushing. It seems quite natural to classify crushing into three stages: coarse, medium, and fine.

For crushing from coarse to medium, jaw and gyratory crushers are mostly used; for crushing from medium to fine, stamps, Chilean mills, and rolls are most prevalent; and for a very fine product, tube-mills, Chilean mills, and grinding pans. On the softer material, centrifugal roller-mills are largely in use, for both medium and for fine grinding.

In both jaw and gyratory crushers the material reaches the crushing field and also discharges from it by gravity, without frictional loss. With these machines, however, there is an important loss by friction of the mechanism, by detrusion, and by the lateral divergence of force that does not crush.

A stamp falling upon a die over which there is a depth of some inches of water, with ore in proper quantity for effective crushing, displaces water and fine particles with great energy, not only to the extent of the cubic measurement of the submerged part of the stamp, but the surrounding water and material is driven outward and upward by that which is so rapidly forced horizontally outward from under the shoe. In this action, at the moment before the arrest of fall, the water is rushed outward over the underlying larger pieces of material with much force, washing by this means the finer particles from under the shoe before the moment of crushing.

The natural course of the material expelled from under the shoe is parabolic, the initial movement being horizontal and its direction of least resistance upward. At the rise of the stamp and into the vacuum created, water rushes and pieces drop back by

gravity, and when other stamps are dropping into the same mortar, the splash from these other stamps adds to the amount to receive the succeeding blow. If, however, the die is but little submerged, when the stamp is at rest, the expulsion of water, at the fall of the stamp, being so much less, the washing effect over the face of the die is proportionately milder, the parabolic course less pronounced and the splash over the screen is weak and limited, especially is this the case if the mortar is wide. Under such circumstances a portion of the sufficiently crushed material splashed screenward fails to reach exposure over the screen surface, from the effect of the expelling blow. Ore that is easily crushed thickens the water that is used in the crushing, much more than does a hard tough ore. The requirements for crushing such an ore are not so exacting as to width of mortar. The thicker pulp keeps more in mass to resist the falling stamp and surges better over the screen surface, whether it is wide or narrow.

A stamp dropping 100 times per minute and crushing 6 tons in 24 hours, would crush an average of $^{1}/_{12}$ of a pound at each blow, or less than a depth of $^{1}/_{32}$ of an inch over a die 8½ inches in diameter.

As the faces of stamp-shoes and dies do not coincide closely in outline, it follows that most of the finely crushed material is produced by the effective pressure of particles between particles. The concave face of the shoe serves to confine the particles under pressure within, against lateral pressure. Under such conditions the crushing efficiency increases with the force of the blow. The force of a blow from a gravity-stamp is due to weight of stamp and length of drop.

A heavy stamp occupies but little more mill-space than a light one and has no more working parts. Its manipulation in re-shoeing and repairs is, however, more laborious.

A stamp dropping evenly upon a die that is unconfined, expels radially with equal force. If the die is encompassed by a concentric wall sloping so as mildly to compress the natural parabolic line of discharge, and if at proper height this wall has above it a concentric screen properly affixed, the expulsion from under the stamp and upward over the screen, and the return of the coarser particles by their gravity and the suction from the rising stamp is regular and even throughout, and the exposure to the screen-surface of the particles direct from under the stamp is at a maximum. Any break or disturbance from this even course is necessarily a departure from the maximum. A stamp dropping upon a die that is one of a group within a mortar, dispels over a screen-surface only a fraction of its product and an important percentage of the passable product returns again to the crushing field. In the former case, a minimum amount of slime is made and a high proportion of screened product nearly up to passable screen size, whereas, by the latter, slime is made and the material discharged through the screen will average finer and the product will be less even in size. Thus under similar conditions, the output from an individual stamp should be greater through a given screen, than from a stamp grouped in a mortar with others. Stamps grouped in a mortar require less room, have less working parts, and are simpler to operate than a like number of individual stamps.

The gravity-stamp is a mechanism of simple con-

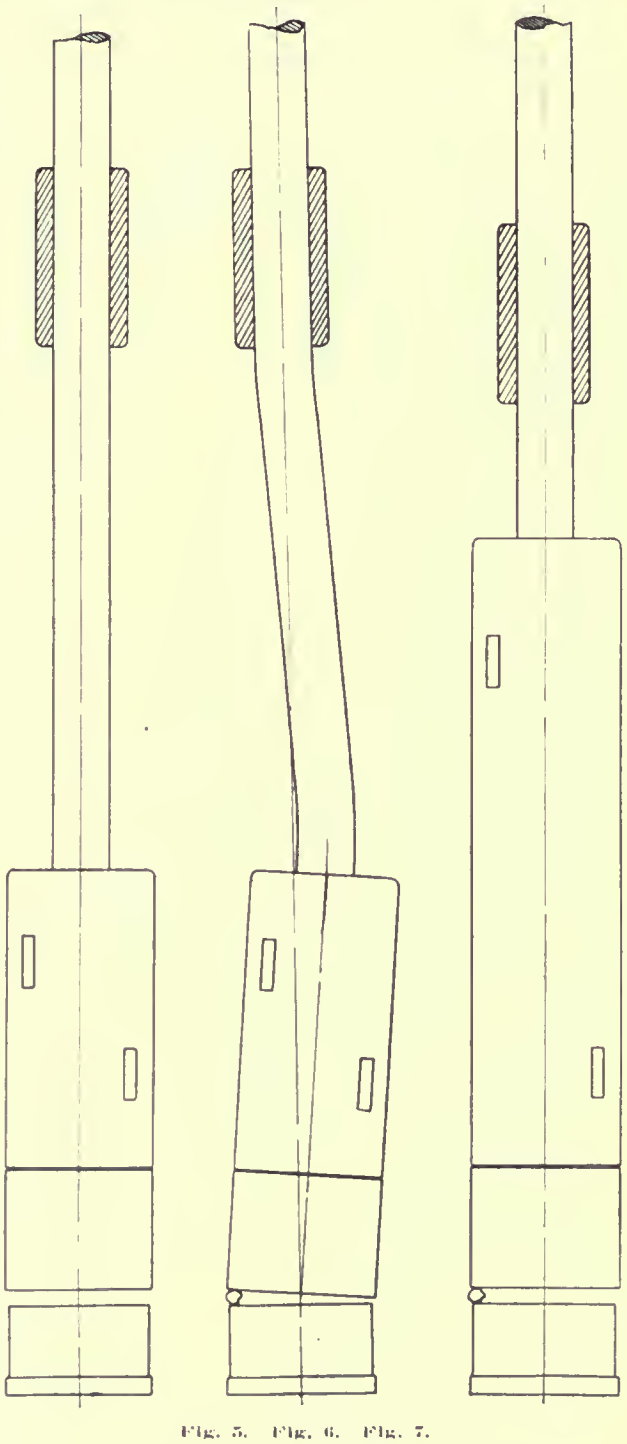

Fig. 5. Fig. 6. Fig. 7.

Fig. 5 shows a stamp of common design and proportions. Fig. 6 is the same stamp, showing (by exaggeration) how the stem is caused to spring. The spring is followed by vibration and continued vibrations cause stem breakages. Fig 7 shows how stem vibration is so minimized that breakage of stems rarely occurs. A long stamp-head, with the lower guide set low, permits but little spring.

struction and its wearing parts are easily renewable. The regularly recurring drop of stamps, in action, generates vibration of the foundation and framework, which is the one trying element of construction. An individual blow from a stamp creates but small square-inch pressure at the bottom of the

mortar, but the rhythmic recurrence of drops vibrates even the earth upon which it stands, sometimes noticeable hundreds of feet underground. There are two sources from which this vibration is generated; first, from the cam-shaft in picking up the stamps, and second, from the mortar that receives the blows. Low and flat foundations are better to minimize vibration than high pedestals.

The vibration in the stem of the stamp is distinct from, and independent of, the vibration in the foundations of the battery. The material upon which a stamp falls is uneven in size and is not evenly distributed over the die, so that the arrest of the blow will usually be mostly away from the axial centre of the stamp, which will give a lateral strain or wrench to the stem. The vibrating effect of this strain upon the stem varies with the structural design. A high centre of gravity of the stamp, the lower guide high above the die, and guides wide apart, are factors conducive of vibration. The stems in such a battery construction usually will begin to break after having been about a year in operation.

By making the stamp-head long and the stem not unnecessarily so, thereby bringing the centre of gravity low, and by putting the lower guide as close to the head as its convenience of operation will admit, the vibration of the stem will be so minimized that breakage is practically eliminated from consideration. Heavy stamps that operate rapidly by steam, upon a thick bed of material, crush largely by particles between particles. They are remarkably efficient for coarse crushing.

A vertical roller running over a horizontal circular track (a Chilean mill) drives liquid pulp before it in a direction tangential to its track, which direction leads away from the crushing zone. If the confining rim or wall of the mill is sloping, the material flows upward in its onward course until its propellant force is abated, at which moment it recedes, more or less, to the crushing zone. If this recession of material is interrupted by an on-coming roller, it in turn obstructs the natural flow generated by that roller. If in the sloping rim there is an encircling belt of screen, the flow over it, if uninterrupted, will be uniform and regular and a high percentage of the fines will be liberated through the screen. On the other hand, if rollers follow one another so quickly that the return of the flow is interrupted, a portion of the confined material, that is sufficiently fine, is restrained from screen contact. Furthermore, if the flow is not interrupted, its containing coarser material will largely have found rest upon the crushing track, in proper position to receive the on-coming roller. In other words, it may be said, if proper space of time elapses between the passing of the rollers, the coarser material gets into position most efficient to the crushing, and if this coarser material has not reached that point of rest, it is an element of obstruction to the systematic exposure of fines over the screen.

In such a mill as described, more material is deposited upon the outer confines of the track than upon the inner. To remedy or ameliorate this defect, the track is sometimes made the truncate of a cone, instead of being a true plane. In other cases the track is made very narrow, to minimize the difficulty, and yet at other times scrapers are employed to equalize the material over the path.

A vertical roller, the tire to which is cylindrical, passing over a circular track, has a forward slip at the larger circumference of track and a backward slip at its smaller circumference, between the two there is a neutral point where there is no slip. In the operation of crushing rock, this neutral point varies in radial distance from the axis, around which the roller revolves, a hard substance raising the roller clear of other contact would, for the time, become the neutral point, irrespective of its radial distance. With a given width of tire, the slip, in making a circuit, is approximately the same on a track of small diameter than it is over one of large diameter. The percentage of slip to travel is in ratio with diameters. The friction from this slip is a resistance to the departure of the roller from a straight line of travel and augments the outward centrifugal thrust.

All outward thrust that is resisted otherwise than upon the material being crushed is lost force. To utilize this lost energy, different modifications are employed.

If a roller runs upon a circular track, the face of which is an inverted truncate of a cone, it will maintain its equilibrium without thrust, either outward or inward, when the speed is properly gauged to the angle of incline. If, however, the speed is unduly slow there will be an inward thrust upon the shaft collar, but if the speed is excessive, the thrust will be outward. The requisite for speed increases when the roller is more inclined from the vertical.

If the axis of a roller is parallel to a diameter line of the circular track and at a distance behind it, the line of rotation of the roller will be tangent to a radius shorter than the radius of the track. Inasmuch as the roller travels on the track radius, it follows that there must be a side slip to the extent of the difference of length of the two radii. This slip is a resistance counter to centrifugal force and they may be adjusted to entirely neutralize. Thus the resistance to centrifugal energy, in such a case, is wholly through the bed of material.

If a roller having a cylindrical tire, passing over a circular track, is horizontally trunioned to the driving mechanism, at right angles to the roller axis and at some point below it, centrifugal energy exerted above the trunion centre is diverted downward upon the crushing, by the trunion pull. This may be termed a plus quantity. The centrifugal energy below the trunion, in like manner is diverted upward and is a minus quantity. The difference between the two represents the amount of centrifugal energy utilized upon the crushing. The energy that is not utilized is resisted by the trunion.

In the passage of a vertical roller over a circular track which is a true plane, the material is thrown outward and when it flows back, more of the material is deposited near the outer periphery of the track than farther inward. As at this point the roller slip is forward, the pressure is greater than

at the point of neutrality, while where the roller slip is backward, the crushing pressure is less. For these reasons the working efficiency is greater at the point where the slip is forward. This work has an effect upon the working faces of the mechanism that is peculiar and very pronounced, when the roller tire is wide and the path upon which it runs is of small circumference. At the edges of the track the pressure is low because of the lateral relief without the crushing zone. At these points the wear is minimum. A little inward from the outer periphery, where the pressure is greatest the wear is very pronounced and deep. At the neutral point it becomes less again, from which place it increases

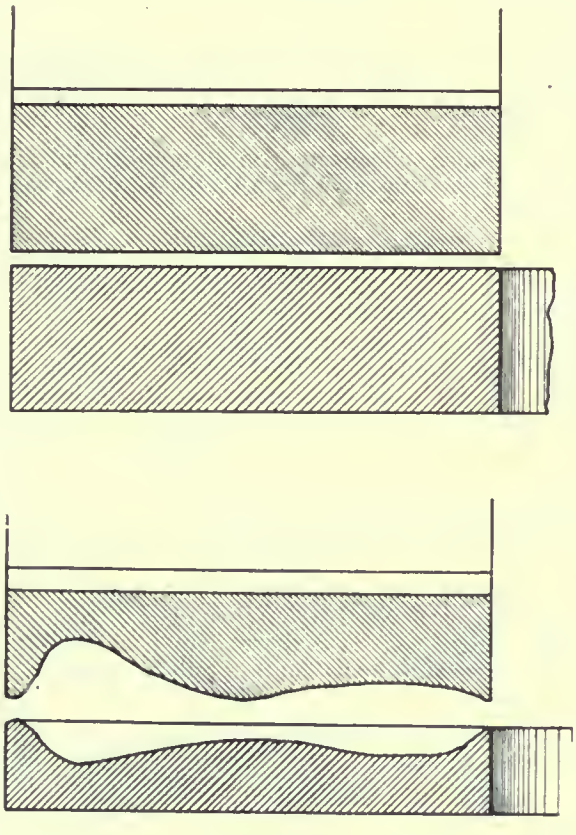

Fig. 11.

This is approximately the outlines of wear of tire and track in a Chilean mill having a wide tire and a track of small circumference.

in depth to a point a little removed from the inner edge of the track. With this class of crushing, vibration is not an important factor.

From the foregoing, a natural deduction favors a narrow crushing zone, having a track of liberal circumference.

Horizontal rolls do but little crushing of particles between particles and the material passes the crushing field without recurrence. As wear across the face of the roll cannot be true and even, the product cannot be made uniformly very fine, but under conditions where the rock pieces are not so large as to give too obtuse an angle of pressure and where the pieces of ore enter the crushing zone at a speed approximately the same as the periphery of the rolls, the work that they do is with small loss of power. The wear and the care of rolls is a matter of importance.

A horizontal roller running over a track, the face

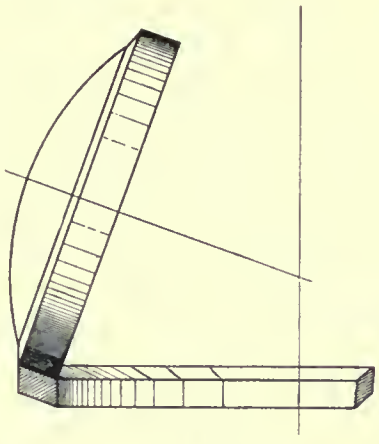

Fig. 8.

This shows a Chilean roller operating upon a track that is an inverted truncate of a cone, to neutralize centrifugal thrust.

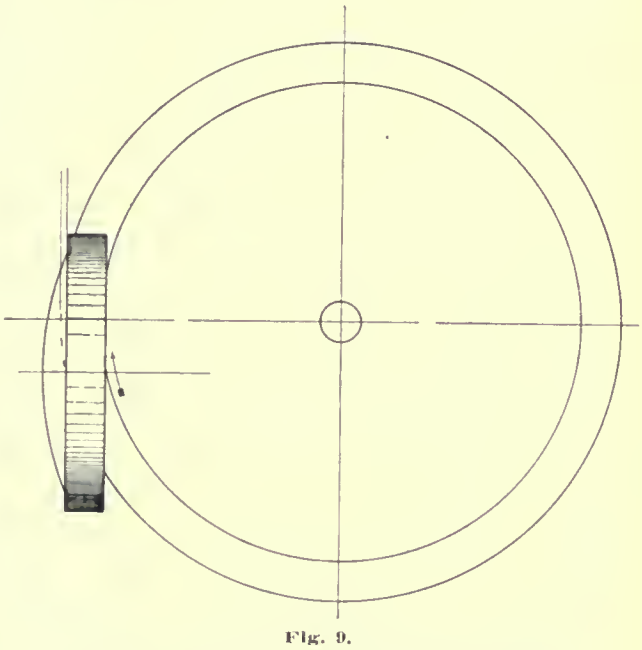

Fig. 9.

The axis of this roller is behind the diameter line, but parallel to it, which gives counter resistance to centrifugal thrust.

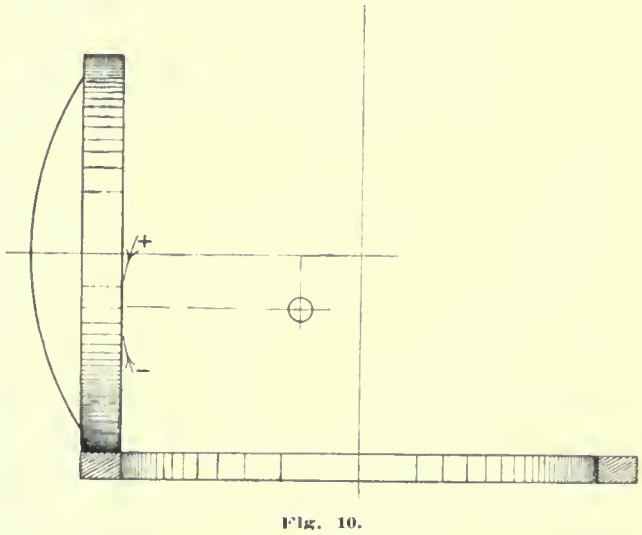

Fig. 10.

A trunion centre is here shown in its relation to a Chilean roller, to which it is attached. The downwardly diverted thrust is shown with plus sign and the resisting upward thrust is shown by a minus sign.

of which is vertical, acts with centrifugal energy upon the material caught between the two faces. From

the nature of conditions, in this class of crushing, there is little crushing of particles between particles, but it is almost wholly done by direct contact between working faces. Speed, to generate pressure, is an essential element with this type of crusher, but the passage of rollers over the path must be properly timed, to catch the material against the track at the proper moment, and it is a requisite condition that the body of moving material shall not be excessive within the mill.

Grinding pans which operate upon a material into which the finished product is discharged, work against a heavy discount of efficiency, as the feed is encumbered with an increasing amount of material that should have been permanently expelled from the crushing field. When grinding between two discs is desired, the highest efficiency and economy is attained by a flow through and away, with the finished product. If the lower disc is made to revolve, it, by centrifugal action, assists the feed between the discs and better keeps alive and in action the material upon it which is being treated. Dise grinders, when properly conditioned, do not altogether rub over and wear away the particles, but they also fracture, more or less, the larger particles. One feature of disc-grinding is, that the coarser particles between the discs are the ones that contact and are acted upon. Discs, to operate with highest efficiency, should contact closely at and near their outer periphery, but should be slightly apart toward their centre, at the point of feed. This is accomplished by cutting open spaces in the discs radially from the centre extending but partly across its base. Disc grinders are very simple in design and of low cost.

Tube-mills containing pebbles for grinding, present an exceedingly great amount of very cheap grinding surface, as each pebble is a grinder. In this feature tube-mills are incomparable with any other class of grinder. However, the material that becomes fine near the feed end must continue on through the tube. Grinding in tube-mills effects no selection of the coarser particles, amidst the pebbles, to be acted upon, but action is with equal facility upon all particles within the field. The loss, within the mill, by friction that is inefficient in grinding is probably great.

From the foregoing, it appears that stamps and Chilean mills, when best constructed and operated, forcefully wash over the material bed, in advance of the crushing moment, and the fine, carried by the wash, passes directly to screen exposure. With such action a high percentage of duty is obtained.

Stamps, Chilean mills, and rolls are pioneers in the ore-crushing field. They are each of them simple in design and are durable. It seems probable that they will continue permanently, under various modifications, as popular crushers. Aside from these, there are many devices that have been more or less successfully used, especially in the centrifugal roller class. Sensational claims for peculiar devices appear from time to time, but it must be kept in mind that to put coarse ore that is hard and tough into fine particles consumes power.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

NOTICE.—Owing to the large number of specimens forwarded to this department, it has been found necessary to make a charge of 25 cents (to subscribers) for each determination, in future.

A specimen of sanidine trachyte was received from C. E. B., of Seattle.

W. B. MeC., of Helvetia, Ariz., sends a specimen of hornblende-diorite.

A. & Sons, Joseph, Idaho, sends: No. 1, hornblende; No. 2, magnetite.

The two specimens from H. W., of Burrough, Cal., are: No. 1, mica-schist; No. 2, manganese dioxide and limonite.

A specimen of quartz containing thin plates of specular hematite came from G. B. W., of Aguascalientes, Mexico.

A. T. T., of Arizpe, Mex., sends a specimen of volcanic breccia, made up of angular fragments of rhyolite and quartz-porphyry.

The rocks sent by W. B. H., of San Francisco, are: No. 1, diorite, somewhat schistose; No. 2, kaolinized rock, perhaps an altered diorite.

T. B. T., of Codova, Alaska, sends: No. 1 and 2, quartzite stained with copper oxide; No. 3, chalcocite and bornite; No. 4, bornite.

The rock samples sent by C. A. F., of Jacksonville, Cal., are: No. 1, talc-schist; No. 2, mica-schist; No. 3, quartz vein in diabase; No. 4, chlorite-schist. All of these specimens contain cubes of pyrite.

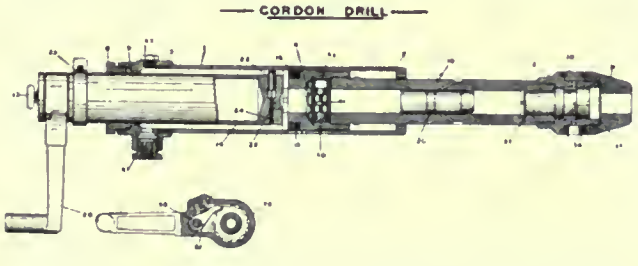
W. L. G., of Fairview, Nev., sends: No. 1, quartzite; No. 2, hematite; No. 3, quartzite; No. 4, basalt; No. 5, basalt; No. 6, quartzite with oxidized pyrite; No. 7 and 8, calcite: No. 9, quartzite and limonite.

Engineering theory and practice are rapidly extending with the general advancement of our economic interests, and the engineer, whether he be a young graduate or otherwise, who does not make use of the modern aids to information, among which are to be counted scientific societies and a personal association with his brethren, with the innumerable hints and suggestions which come from these, will soon be found struggling with what seems to him adverse fate, but what in reality is inferior knowledge, behind-hand knowledge, or, plainly speaking, ignorance, greater or less. The engineering world has passed by him, and he must view the working out of the law of the survival of the fittest with what grace he may.—C. W. Hunt.

Moss copper, which is frequently seen on copper matte, is due to the decrease of solubility of copper metal in copper matte as the temperature decreases. Solid solutions obey many of the same laws as liquid solutions, and thus many obscure phenomena can be explained.

DRILL CONTEST ON THE RAND.

Stope-drills is the all-absorbing topic on the Rand. The question of replacing the 53,000 Chinamen who are now about to leave the Rand has been the incentive for a thorough investigation. The leading mining paper in the Transvaal, *South African Mines*, has shown great enterprise in offering a prize for the best small rock-drill as demonstrated in open competition under carefully selected judges. The large amount of special information on the subject that has been obtained thereby, will prove of immediate value, and should bring about tangible results in the reduction of working costs, because the contest has given the data upon which a useful discussion can be based. About 300,000 ft. of drill-holes are being drilled each day at a cost of £20,000, and if manual labor can be replaced by a cheaper mechanical hammer, there will be from 2000 to 5000 machines used in the mines of Johannesburg. That any method will find universal application is unlikely, but the remarkable results obtained in the competition show that this phase of engineering



has been sadly neglected by mechanical engineers, who only too often consider that their responsibility ends at the collar of the shaft.

Comparisons between drills, under conditions as uniform as possible, are of the greatest value if properly interpreted, in giving information concerning certain phases of drilling, such as design of the machinery and actual speed of drilling. Of the cost of maintenance and repairs, little can be ascertained except by continued use. The trials have borne unexpected fruit and if properly interpreted, they afford valuable data for engineers in the selection of machines. Every engineer has had the experience of interviews with manufacturers' agents each of whom could explain exactly why his own particular machine was 100% better than that of any competitor. The mine managers at Johannesburg now have the results, carefully tabulated, of a series of tests made under identical conditions with a view to testing the mechanical efficiency of the machine on the surface and under working conditions. The results are surprising, and we can deduce more than mere generalizations.

The Gordon drill did the best work. It is named after W. D. Gordon, the American vice-consul at Johannesburg, and was put on the market by the Ingersoll Rand Co. The average for a full four days run was 1.69 inches of drill-hole per minute, a truly remarkable performance as compared, for instance, with Kaffir hammer-boys. In the hands of a native this drill has proved its ability to drill 11 to 12 holes, 3 ft. in depth, in less than 5 hours. The figures prove the superiority of the hammer type over that of reciprocating or percussive drills. The percussive machine of the present day has nearly reached the highest possible efficiency of this type of rock drill, and it is doubtful if it will ever show much increase in drilling power. More economic valve motions may be designed as far as air-consumption is concerned. Hammer-drills are still in their infancy, but the work done per pound of weight far excells that of the percussion type. The present tendency is to revert to the principle of the single-hand hammer, by making a machine that merely strikes the drill without withdrawing the drill at each stroke.

The drills were tested at the surface by two runs of four hours each in granite, the air being supplied at 50-lb. pressure for the first trial and at 60 lb. for the second.* The size of holes was to be 1¼ in. at the bottom. The holes drilled in the contest were to be from 36 to 45 in. deep and the drills operated by one man without a helper. The contest was decided on footage and time, as no estimates could be made of cost of maintenance or repairs.

The following table shows the depth drilled in the surface tests and the percentage increase obtained by the additional 10-lb. pressure. The amount of air used was not measured, but the pressure was kept constant. The following table also shows the piston or hammer displacement of each drill:

Name of Drill.	Depth Drilled at 50-lb. Air-Pressure.		Depth Drilled at 60-lb. Air-Pressure.		Increase in depth.	Piston or hammer at 50-lb.	Displacement per min. at 60-lb.
	Ft.	In.	Ft.	In.	%	Cu. In.	Cu. In.
Kimber	12	11¾	16	11	30.6	Not determined.	Not determined.
Little Wonder	16	7⅞	19	11⅜	19.7	8,460	9,964
Gordon	28	4⅞	36	9¼	29 5	5,617	6,771
Little Kid	15	9⅜	22	6⅛	42.6	6,782	7,928
Baby Ingersoll	25	3	29	6½	17.0	10,945	12,736
Flottmann	18	9⅜	25	4⅜	34.4	10,395	12,166
Little Holman	14	4¼	17	0¼	18.6	7,065	8,321
Chersen	26	5¼	33	2	26.0	18,868	20,648
				Mean Increase	27.3		

The underground tests consisted in drilling 8 down-holes and 8 up-holes at the angle of the lode.

Drill.	Type.	Weight, Lb.	Cylinder, In.	Stroke, In.	Feed, In.	Average drilling in inches per min. dry holes.	Average drilling in inches per min. wet holes.
Gordon	Hammer	72⅝	1 13/16	10	10	1.74	1.82

Chersen	Piston	113⅝	2¼	6	18	0.27	1.11

*The air-pressure used will impress American mine managers as being too low. The inefficiency of low pressures is now receiving more attention on the Rand. Small drills, as a class, require higher pressures than large ones, and the hammer type than reciprocating machines.

and setting up in a new position for each set of four holes.

The trials differed from ordinary practice in so far as the drill in the stope is set up each time a hole is drilled. The following table gives the results and some details of construction of each drill.

Of these drills, most are too heavy to be considered one-man drills, and only those weighing less than 80 lb. can be considered suitable for a single operator. In addition to the above drills, the Flottmann and Hardsoeg drills, weighing respectively 52¼ and 44¼ lb. were represented. These machines, however, did not finish the tests, owing to inferior steel and other causes, and little information as to their value was obtained.

A feature of importance in stoping drills is that they must be easy to set up quickly and light enough to take into the stopes. On the Rand, and in many districts where the veins are narrow, only one hole is drilled at each placement of the drill, and it is important that the holes be arranged so that, in blasting, full advantage is taken of each seam or selvage in the rock. It is in this respect that machine-drills have been vastly inferior to hand-labor for stoping narrow deposits. In this connection we note that one of the most striking features of the contest at Johannesburg was the rapidity with which the Gordon drill was erected and adjusted and its steel changed. Bolts were entirely absent on the column and arm, their place being taken by steel wedges. Much time was undoubtedly saved by this simple and effective device, and it would be interesting to know whether the idea would give satisfaction with the heavier blows of reciprocating machines. In order to derive the greatest benefits from small machines, they have to be erected several times in the course of a shift, so that full advantage may be taken of all slips and places of weakness in the rock. In this respect the Gordon is useful, as it is entirely free from projections and is cylindrical in form. Bad drill-steel was also the cause of much trouble, and the importance of careful tempering and gauging was clearly demonstrated. The Gordon was the only drill that used water in the 'uppers,' and to this is largely due its remarkable performance. The water is fed through the hollow drill to the bit, and by this means the hole is kept clean and the steel cool, while all danger of phthesis, due to the inhalation of dust by the operators, is entirely eliminated. With the 200 Gordons just received at the Rand Mines Ltd. and the Little Kid and others already at work, it is to be hoped that the problem of cost will be investigated. The question of wear and tear, of the wages that will be demanded by the operators, and the advances that will undoubtedly be made in the design of these drills, are questions which time alone can solve, but there is no doubt that these tests will prove of the utmost value to the manufacturer of the drill and the manager of the mine, whether in South Africa or elsewhere.

Prospecting for tin has been often carried out in Trabuco canyon in southern California, and a small quantity of ore produced.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

The owner of all the coal, gases, salt water, oil, and minerals of every kind and description, in, upon, and under a certain tract of land supposed to contain a certain number of acres, together with rights of way and mining rights, is not the owner of such an estate as will entitle him to maintain an action for partition. The rule has been stated thus: A grant of an undivided interest in a piece of mining ground expressly conditioned that no rights are conveyed, except a mining right upon the premises, vests in the vendee only the right of taking from the land any minerals or ores contained in it, to the extent of the interest granted. He does not by virtue of the conveyance become a co-partner, joint tenant, or tenant in common with the vendor in the land itself. His interest is not an estate which can be the subject of an action for partition.

Robertson Land Co. *v.* Paull, (W. Va.) 59 Southeast. 1085, Dec., '07.

Where a person undertook to 'jump' a mining claim on the theory that the required amount of assessment work for a particular year had not been done, he was not permitted to assert thereafter a forfeitnre of title for failure of the original locator to comply with the rules of the mining district, respecting the giving of notices of location, where such original locator had gone beyond the preliminary notice and marked the outlines of the claim, and such re-locator had full knowledge of the location and boundaries of the original claim, and where he undertook to locate his new claim precisely within the boundaries of the old one. The concrete rule is that a person with full knowledge of a former location and of the outlines of the claim cannot re-locate the claim within the same boundaries on the ground that the assessment work had not been done, and then claim a forfeiture on the ground that the notices required by the mining district regulations had not been given.

Yosemite Mining Co. *v.* Emerson, 28 Sup. Ct. Rep. (U. S.) 196, Jan., '08.

On failure to perform the assessment work, a mining claim is open to re-location in the same manner as if no location had ever been made, provided the original locators, their heirs, assigns, or legal representatives have not resumed work on the claim after failure and before such re-location. But where there has been a failure to perform the assessment work within the time specified, but the original locator, after such failure had, in good faith, resumed work upon the claim, the claim is not then subject to re-location, on the ground of the original failure. Whether or not such work has been resumed is a question of fact; and when a trial court or jury has so found, such finding will not be disturbed on appeal.

Yosemite Mining Co. *v.* Emerson, 28 Sup. Ct. Rep. (U. S.) 196, Jan., '08.

The extraction of coal by one tenant in common of a mine, without the consent of the other, is regarded as waste, for which he is liable to account. He will not be heard to say that his co-tenant may proceed to take coal from other parts of the vein or mine owned in common. While the coal in land is partible, still there is an appreciable element of uncertainty touching it, great enough to forbid a court of equity from depriving a party of his right in what is in the land for what may never be there. Hence, one tenant in common who has taken coal from the common mine, cannot compel his co-tenants to take their share in undeveloped land with its coal which they could mine if they chose, but must account to them for their share of the money received for the coal mine.

Robertson Land Co. *v.* Paull, (W. Va.) 59 Southeast. 1085, Dec., '07.

COAL IN COAHUILA.

Written for the MINING AND SCIENTIFIC PRESS
By EZEQUIEL ORDOÑEZ.

Everybody knows that the State of Coahuila is the only actual coal-producing region in the whole of Mexico, though several coal districts exist in some of the other States, such as Sonora, Puebla, Guerrero, Oaxaca, and a large belt of unknown importance on the Gulf coast of Veracruz. Various conditions prevailing in these regions have made difficult a thorough knowledge of their real importance as producers of fuel, although there is in Mexico a constant demand for coal to supply the needs of industry, apart from the consumption of mining and metallurgical operations and railroads. Among the unfavorable factors are the lack of railroad transport, want of sufficient capital available, and a certain absence of confidence due to the general idea that these coal deposits are not sufficiently extensive to guarantee such a large production as is required to insure a profit or an adequate return on the large capital to be invested. On the other hand the strong encouragement given by railroad companies to the importation of fuel from northern America is detrimental to the exploitation of Mexican resources and places the coal industry of Mexico in weak position to meet competition.

With a revision of coal tariffs by the Mexican Government and a reasonable taxation on the import of coal, the coal industry of Mexico would become prosperous and it could take rank among the best investment business of the country. It is possible that the Government may shortly be persuaded to take measures to protect in some degree the home coal industry in view of the large amount of capital that is being invested; especially in the coal measures of the State of Coahuila. In any case, any legislation ought to recognize the difference in the quality between the national and the foreign coals: the Mexican is inferior because it has less heating power, a large content of ashes, and is unsuitable for certain uses.

The more protection the Mexican Government gives to the home coal industry, the more encouragement there will be not only to prospect and develop the new coalfields, but the tendency will be to enlarge the present producing capacity of the Coahuila mines, as many of them are now open and preparing new working places, new slopes, and big shafts, erecting plants for washing, building coke-ovens, and so forth.

Such favorable action by the Government would not injure the foreign coal interests nor home railways, since our coal industry is owned in small measure by foreign capital and the railways will secure the profit attending the increasing domestic coal transportation.

Of the 2,000,000 tons of coal and coke consumed yearly in this country, at least 1,000,000 is produced in Mexico, and perhaps a little more: all this coal comes from the Coahuila mines. This coal fills only the needs of the northern part of Mexico and a little export to Texas. The Coahuila coal cannot enter into competition with the foreign product coming by sea from the ports of Veracruz and Tampico on account of the better grade of the latter and the cheaper transportation it obtains.

It is believed that our coal will be better in quality if the producers pay more attention to their deliveries, adopting better methods of classification and washing improved in order to extract the impurities that it always contains, due to a slate bed present between the two thick beds of coal existing in the Coahuila formation.

We do not expect to see Mexican coal cheapened at once, although we may hope to get a better class of fuel, because the cost of production is more likely to increase than to diminish on account of the use of foreign labor. It is well known among coal investors and engineers that Mexican labor is probably one of the least efficient in coal mines, although it gives excellent service in the metal mines. The Mexican miner has a horror of the coal mines and never understands how to guard against the danger of the gas. If he goes to the coal mines it is because he has become discouraged in his effort to get work elsewhere, and is attracted by the better pay.

The Coahuila coalfields cover a triangular space, of which one side is the Rio Grande from northwest of C. P. Diaz to near Laredo, that is, a little more than 100 miles. The other two sides extend from a little north of Monclova to C. P. Diaz, and from Monclova point to Laredo. That means a surface of about 3500 square miles with some extensive barren lagoons in its interior. Inside of this large territory two kinds of coal are found. One, occupying an almost uninterrupted belt along the Grande river, gives a brown coal; the rest of the surface gives coal of the coking class. The coking coal is interbedded in the Upper Cretaceous rocks or Laramie formation, which in Coahuila forms a number of large and small basins closely connected, that is, separated from each other by narrow anticlines. In general, the coal basins are shallow, the synclinal axes rarely go as far as 600 ft. deep.

The Upper Cretaceous formation in which the coking coal occurs consists of three well marked series of rocks, two underlying the coal beds and the other containing it. The deepest series, called the Peyotes division, is composed of a great number of thick beds of limestone containing *Inoceramus* and divided by thin beds of black shale. The second series is best known in the southern basins; we call it the Rubio or Monclova shale; it is a thick and homogeneous group of shales separated by thin beds of limestone and sandstone, all of which are highly fossiliferous. The coal series itself, known as the Las Esperanzas formation, is composed of shale and sandstone, both rocks sometimes very thick. Groups of sandstone beds reach a thickness of 40 to 50 ft. and the shale is sometimes as much as 100 ft. During exploitation trouble has arisen in some places on account of a slight faulting of the beds. There are gradations from shale to sandstone and the latter varies in composition, some of it being very silicious. The sandstone is generally called *piedra de amolar*, others are calcareous, glauconitic, etc. The shale sometimes passes into soft marl and is then

called 'blue mud.' In shallow basins the sandstone comes close to the coal beds, with intercalations of thin shale, but the upper wall of the coal bed itself is always soft. This makes exploitation expensive on account of the heavy timbering required.

As said before, there are generally two coal beds separated by a hard shale and each coal bed contains some hard and thin carbonaceous shale called 'bone' by miners. The upper coal bed is always thinner than the lower coal seam. The former ranges from one to six feet thick, the latter from four to eight feet thick and rarely more.

The character of the coal is shown by the following data: Sp. gr., 1.40; volatile matter, 16%; fixed carbon, 60 to 65%; ashes, from 12 to 18%; moisture, about 1%; coke, about 80 per cent.

The basins most exploited are the Las Esperanzas and Sabinas, the latter extending on both sides of the Sabinas river. In this tract systematic work was begun about 18 years ago and it soon gave signs of being an important coalfield. Two or three new basins have been discovered recently, some of them much more important in extent than the old discoveries. One of these is the Saltillito basin, where some work has been commenced. Drilling and prospecting are in progress, with satisfactory results, adding to the territory available for future exploitation and increasing the known area of each basin.

The entire coal industry in Coahuila represents a capitalization of nearly 35,000,000 pesos. It gives occupation to 7000 people and moves nearly 100 carloads daily over the International Railroad, the centre of distribution being at Monclova.

The production of coke is an important industry and represents the proper use of the Coahuila coal, for most of this coal gives a coke comparable in quality to the foreign coke.

When those parts of Mexico that contain anthracite and coking coal are exploited on a proper scale, the country will get coal for every purpose and will render unnecessary the importation of foreign fuel.

The Coahuila coal basins are operated by the following companies, some of them having started only lately: The Coahuila Coal & Coke Co., The Mexican Coal & Coke Co., The Compañia Carbonifera del Norte, The Compañia Carbonifera de La Rosita, Compañia Carbonifera de la Agujita, Compañia Carbonifera de Lampacitas, Compañia Carbonifera de San Blas, Compañia Carbonifera de C. P. Diaz, and the Compañia Carbonifera de Rio Grande.

Map of Mexico.

Primary Bornite in Colorado.—Bornite and chalcopyrite occur as rock-minerals at the Evergreen mine, at Apex, Gilpin county, Colorado. There is here a dike of eruptive rock composed of quartz, orthoclase, albite, augite of the aegirine variety, and long needles of enstatite and diallage. It is 3 to 12 ft. wide and can be traced at the surface 1500 ft. Some of the ore of the mine has been produced by secondary deposition along cracks in the neighboring rock, but a large proportion of the ore is found in the dike itself. Unaltered bornite and chalcocite grains occur as inclusions in the quartz, feldspar, and augite, and in the clusters made by the needles of enstatite and diallage. These copper sulphides must have come up dissolved in the magma at the time of its ascent to form the dike, and must have crystallized together with the silicates in the eruptive rock.

QUICKSILVER MINES OF OREGON.

In the last volume of 'Mineral Resources of the United States,' just issued by the United States Geological Survey, the following is said regarding the quicksilver resources of Oregon:

"Oregon had been a small producer for several years, but in 1906 had it not been for a new producing property, its production would have been nothing. The main operator in 1906 was the Almaden Gold & Quicksilver Co., at Howard, Crook county. The most extensively developed property in the State, the Black Butte mine, which also has a thorough equipment with a special furnace and retort, is understood to have remained idle. Considerable prospecting was carried on in Jackson, Josephine, and Douglas counties, and several occurrences of ore of good grade are reported. The greatest activity was in Meadows district, in Jackson county, where a depth of 400 ft. is stated to have been reached and a furnace and retort erected.

"At the Black Butte quicksilver mine in Lane county, Oregon, an experimental furnace, designed by and named after the general manager of the property, and known as the Dennis roasting furnace, was built in 1905, but was not operated in 1906, as the mine was not producing. It was constructed to secure, at minimum cost, perfect combustion for a large tonnage of low-grade ore. The small furnace comprised a series of primary and secondary combustion chambers and a number of other special devices, including one for preventing loss by the escape of raw-ore dust. In test-runs it is reported to have afforded a thorough roast of ore and volatilization of values in four hours, and to have eliminated practically all loss through flue-dust."

Later information is available as follows: During the year 1907 the Black Butte mine, referred to above, was equipped with a new and extensive plant consisting of a hydro-electric power and lighting plant; a crushing plant composed of the buildings and ore-bins, arranged on the gravity plan, having a storage capacity of 600 tons, and crushing capacity of 200 tons per day of 12 hours, equipped with a Sturtevant coarse-ore crusher and a Gates gyratory fine-ore crusher; a new special designed dryer built of brick, concrete, and iron, having a capacity of 125 tons; and a condensing plant, constructed and arranged after the special design of the manager of the property, which successfully discharges the furnace gases at or below atmospheric temperature, thereby insuring perfect condensation and no loss of silver, either chemically or mechanically. The old Scott furnace on the property has been re-modeled, and further improved by the addition of a specially designed wood-gas producer. The draft is produced by two No. 70 Sturtevant exhausters direct connected to a 35-hp. variable-speed motor, and so arranged that one or both can be operated at one time. The entire plant is constructed and arranged after the design of the patents recently granted by the United States and all important countries, to W. B. Dennis, the manager of the property, and is the outgrowth of the experimental work mentioned in the above quotation from the Government report.

The new plant at Black Butte was started on February 1, and its operation up to the present is said to have been most satisfactory. Quicksilver is reduced from the crude ore into pure metal in market form, and is shipped in wrought iron bottles in car-load lots to New York. An imposing looking village has grown up at Black Butte, 42 miles south of Eugene, as a result of this industry. The mine is owned largely by Mr. Dennis and Portland and Seattle associates. It is one of the heavy tax-payers of Lane county, and is becoming one of the important industries of the State.

Swedish Nickel Ores.—Until about twenty years ago the manufacture of nickel was a flourishing industry in Sweden; it then became depressed through foreign competition, especially of the Orford Copper Co., of Bayonne, New Jersey. This company smelts a Canadian ore, containing copper and nickel, with charcoal and sulphate of soda, in an upright furnace. The greater part of the nickel sulphide remains insoluble, although the sodium sulphide found in the furnace dissolves a large part of the copper sulphide; when the molten mass cools, it settles in an upper layer containing chiefly copper and a lower layer chiefly nickel. By three repetitions of this treatment there is produced a nickel sulphide containing about 1% copper; this is pulverized in a ball-mill, steeped in water to dissolve small quantities of sodium sulphide, and then in dilute sulphuric acid, which dissolves the small quantity of iron sulphide present. By further processes, copper, cobalt, silver platinum, and palladium are separated; the protoxide of nickel remaining is smelted with charcoal to produce metallic nickel. Swedish nickel ores in general contain too much iron and too little nickel to be worked on the Orford plan. It has been suggested that, as the larger part of the metallic nickel manufactured is employed for making nickel steel, the direct production of nickel steel is the only way in which poor Swedish nickel ore can be utilized advantageously. Magnetite pyrite containing 1 to 3% nickel and free from arsenic and phosporus are available. They admit of very simple treatment; the sulphurous gases driven off in roasting them are utilized for making sulphuric acid. The roasted regulus, briquetted and smelted with charcoal, forms nickel iron containing somewhat more than 3% nickel, in which state there is the largest field for its use.

In a large blast made at Smartsville to break a bank of hard cement 80 ft. high, an adit was run in 85 ft. and cross-drifts 45 ft. long were driven at either side from the end of the drift, and at 40 ft. from the entrance. At the end and centre of each drift, two 'lifters' were driven at right angles to it, extending respectively half way to the next cross-drifts and to the face of the bank. After charging the cross-drifts the main drift was tamped and the 450 kegs of powder exploded by electricity. The bank was exposed on two sides for the blast.

COMMERCIAL PARAGRAPHS.

THE A. LESCHEN & SONS ROPE CO. has moved its Denver office and warehouse to No. 1649 and 1651 Wazee Street.

THE SULLIVAN MACHINERY CO. has issued Bulletin 60A, describing hammer drills. The pamphlet gives valuable information about this useful type of machine.

'Cores' is an attractive catalogue published by the CYCLONE DRILL CO., of Orrville, Ohio. It describes the various uses to which these drills can be put, and some useful cost data.

THE AMERICAN SPIRAL PIPE WORKS, of Chicago, announces that it will send to all those interested, circular No. 21, descriptive of its rivited pipe, forged steel flanges, and cast-iron fittings.

THE WOOD DRILL WORKS, of Paterson, N. J., will be represented henceforth in Mexico south of the 23rd parallel by the International Machinery & Engineering Co., Edificio de la Mutua, Mexico City.

THE SWEETLAND FILTER PRESS, which is described in detail in a pamphlet sent by the makers, reduces the cost of labor to a minimum. The machine is made by the Sweetland Filter Press Co., 314-315 Merchants Trust Bdg., Los Angeles, California.

THE SMOOTH-ON MFG. CO. has published a leaflet descriptive of the development and uses of Smooth-On iron cements. The company has established offices at 61-69 Jefferson St., Chicago, Ill.; 20 Sacramento St., San Francisco, Cal.; and at 8 White St., Moorfields, London, E. C.

THE JACOBSON MACHINE MFG. CO., of Warren, Pa., have recently established a southern office at Atlanta, Ga., at which point they will carry a full stock of gas and gasoline engines; also a stock of repair parts. This business will be in charge of C. R. Morrison, who has for some time been traveling representative in the Southern States. The office and store-room is at 676 Marietta St., Atlanta. This company is one of the concerns engaged in the manufacturing of gas and gasoline engines that has not experienced any decrease in the orders received, nor volume of business done.

L. S. PIERCE, 1650 Champa St., Denver, recently shipped two 20-ton Pierce amalgamators through the Allis-Chalmers Co. to Johannesburg, Transvaal; one complete placer machine to Frank M. Barnes, White Hills, Ariz., for use on the Colorado River placers; two 20-ton machines to the Butterfly Terrible M. Co., near Ophir, Colo.; one 20-ton plant to the Texas Flat Mines Co., Raymond, Cal.; two 38 by 47 in., 150 tons each, machines to the Philadelphia Exploration L. & M. Co. of Philadelphia to Gold Hill, B. C. These machines are used in stamp-mills, cyanide plants, placer work, and on gold dredges.

THE ROBINS NEW CONVEYOR CO., which has been recently incorporated, will be operated under the management of Thomas Robins, who founded the Robins Conveying Belt Co. in 1896 and was president of that concern until March, 1907, when its management passed into other hands. The position of chief engineer in the new company is filled by C. Kemble Baldwin, who has served in the Robins Conveying Belt Co. in the same capacity for the last seven years. The offices of the company are at 38 Wall St. and 1240 Old Colony Bdg., Chicago.

THE DEARBORN DRUG & CHEMICAL CO. announces that at the recent directors' meeting officers for the ensuing year were elected, following the purchase of the holdings of the late Wm. H. Edgar and those of C. M. Eddy by Robt. F. Carr and associates. Mr. Eddy has decided to devote all of his time to his personal business interests. The following officers are now in control of this well known company's extensive interests: Robt. F. Carr, president and general manager; George R. Carr, vice-president; Grant W. Spear, vice-president; Wm. B. McVicker, vice-president and eastern manager; J. D. Purcell, assistant general manager; W. A. Converse, assistant secretary and chemical director; R. R. Browning, assistant treasurer; A. E. Carpenter, superintendent.

BOOKS RECEIVED.

'How to Read Plans.' By Charles G. Peker. 60 pages, with drawings. Cloth. Price 50 cents. This little book is to teach how to interpret plans and how to work from a drawing.

'Wilson's Mining Laws,' annotated, with forms and corporation laws of Arizona. By Calvert Wilson. Third edition. 140 pages. Price 50 cents, paper; $1, cloth. This is a useful handbook and has commanded a ready sale among mine operators. For sale by the MINING AND SCIENTIFIC PRESS.

'Mine Gases and Explosions.' By J. T. Beard. John Wiley & Sons. Price $3. 402 pages. This volume treats the subject in a simple way, explaining fully the fundamental principles of chemistry and physics as they apply to the subject. Safety lamps are also described in some detail. For sale by the MINING AND SCIENTIFIC PRESS.

'Analysis of Mixed Paints, Color Pigments and Varnishes,' by C. D. Holley and E. F. Ladd. J. Wiley & Sons. 238 pages. $2.50. This is a concise work on the analysis of paints and paint products. The book enables a chemist of ordinary experience to make a complete analysis of any paint, and also furnishes sufficient data so that the results of the analysis may be interpreted in a rational way. For sale by the MINING AND SCIENTIFIC PRESS.

'Modern Pigments and Their Vehicles.' F. Maire. J. Wiley & Sons. 266 pages. $2. The purpose of this volume is to give a brief history of all valuable pigments useful in painting, and describe the main sources of their derivation and supply; their properties and chief uses; their qualities, and best methods of detecting adulteration. The book is written for the men who use or sell pigments and those who want to know what to expect of them. For sale by the MINING AND SCIENTIFIC PRESS.

'Metallurgy of Iron and Steel.' By Bradley Stoughton. Hill Publishing Co. Price $3. 500 pages. This book covers every phase of iron and steel processes, with a number of interesting illustrations. The author, a graduate of Yale and the Massachusetts Institute of Technology, has had considerable experience in designing, erecting, and managing steel works, and consequently writes in an understanding way. The book is not laborious or difficult. For sale by the MINING AND SCIENTIFIC PRESS.

PUBLICATIONS RECEIVED.

The following folios of the U. S. Geologic Atlas have been published: No. 154, Winslow folio, Arkansas-Indian Territory, and No. 155, Ann Arbor folio, Michigan.

'Ninth Annual Report of the Mining Industry of Idaho,' for the year 1907. By Robert N. Bell, State Inspector of Mines. 216 pages. Illustrated. This is a highly creditable volume; it contains much useful and interesting information carefully compiled.

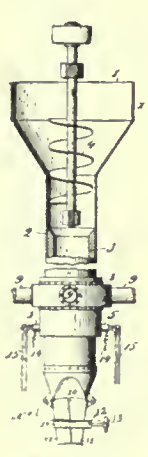
We have received the following bulletins from the U. S. Geological Survey: No. 326, 'On the Arkansas Coal Field,' by Arthur J. Collier; No. 334, on 'The Burning of Coals Without Smoke in Boiler Plants'; and No. 339, on 'The Purchase of Coal Under Government and Commercial Specification on the Basis of Its Heating Value,' both by D. T. Randall.

'The Geology of the Coromandel Subdivision, Hauraki, Auckland.' By Colin Fraser, assisted by James Henry Adams. Published by the New Zealand Geological Survey. This is one of those conscientiously prepared and admirably illustrated monographs for which the New Zealand Survey has made a deserved reputation. It is interesting to note that the gold veins occurring in the Tertiary volcanics of the Coromandel peninsula are like those of the Thames district in so far as their formation is due to solutions ascending from some rock deeper than any now exposed at the surface. In this regard the authors, after making tests on the encasing country, are in accord with J. R. Dow.

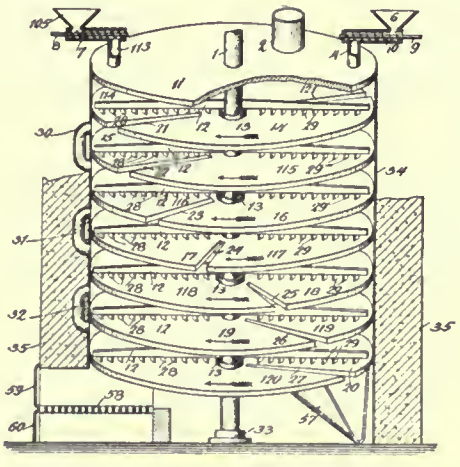
MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE-REDUCING FURNACE.—No. 874,527. James McLoughlin, Rye, New York.



No. 874,527



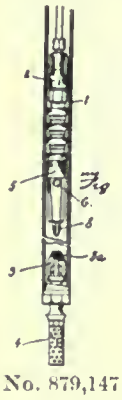
No. 879,842

A furnace for the reduction of zinc-bearing ores, having an elongated furnace body open at both ends, one open end serving for the admission of the ore and the other serving as an outlet for the solid products of the reduction, means for axially constricting the alined outlet of the furnace, means for feeding the material in the ore-chamber of the furnace from the receiving to the discharging end, and means for producing an electric arc in the ore-chamber, said chamber having in its walls fume-apertures disposed between the reduction point and the charging end of the furnace and extending from the ore-chamber obliquely outward and toward the receiving end of the chamber.

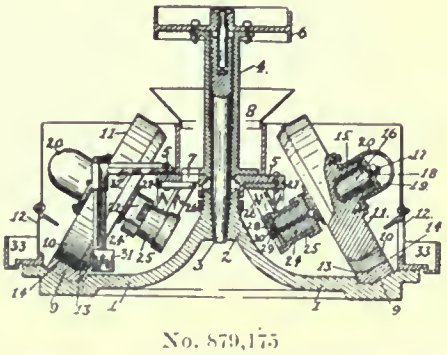
ROASTER.—No. 879,842; Walter G. Swart, Denver, Colorado.

A roaster having a hearth with a plurality of substantially radial slots extending inward from its periphery.

STAND-VALVE EXTRACTING MEANS FOR OIL-WELL PUMPS.—No. 879,147; Evelyn A. Copeland, Tionesta, Pennsylvania.



No. 879,147



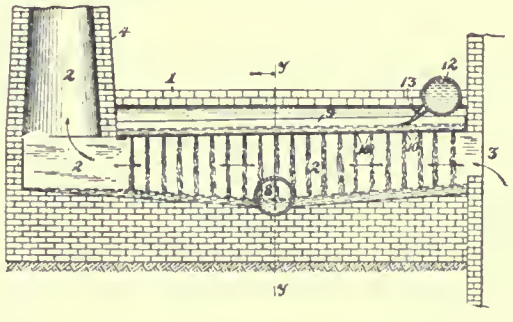
No. 879,175

In means of the class described, the combination with an oil-well pump including a plunger, and a stand-valve having a threaded portion at its upper end, of an attachment applied to the lower end of the plunger and consisting of a supporting member secured to the plunger, and an extracting member mounted for rotation with said supporting member but movable into a position in which it does not project from said supporting member, said extracting member having a threaded portion at its lower end for connection with that of the stand valve.

CRUSHING-MILL.—No. 879,175; Frank A. Huntington, San Francisco, California.

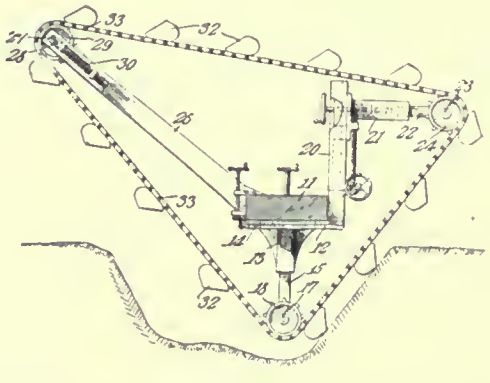
In a crushing-mill of the roller type the combination of a pan, screens in the pan-rim, a crushing roller in the pan inwardly inclined from the bottom upwardly, said roller having the inner side of its crushing surfaces inclined to its axis of rotation to form a straight horizontal portion at the bottom, and having the remainder of its crushing surface parallel with the axis of rotation to form a straight upwardly inclined outer portion; a ring die in the pan against which the crushing roller acts, said die having its crushing surface formed with a straight horizontal inner portion and a straight upwardly inclined outer portion, to correspond with the crushing surface of the roller and a driving means for effecting the orbital travel of the roller in the pan, said driving means including pivotal connections to enable the roller to swing centrifugally.

DEVICE FOR PURIFYING PRODUCTS OF COMBUSTION AND OXIDATION.—No. 879,149; Alexander A. Cunningham, San Francisco, California.



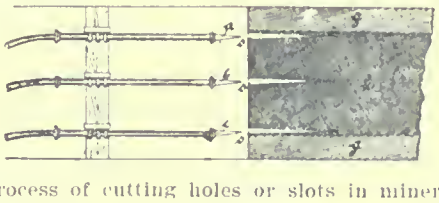
In a device of the character described, the combination of walls enclosing a purification chamber, means for causing the products of combustion and oxidation to pass through the purification chamber, a series of distributing troughs arranged in the upper portion of chamber, and provided with discharge openings, a supply pipe extending transversely across the distributing troughs, and provided with means for supplying the various troughs with a liquid, and means for discharging the liquid from the bottom of the chamber.

EXCAVATING-MACHINE.—No. 879,231; Frank M. Wrabek, Lesueur Center, Minnesota.



In a machine of the class described, a support, a plurality of sprocket-wheels, an endless belt excavator guided around said sprocket wheels, and bearings carrying said sprocket-wheels, each of said bearings being adjustable independent of each of the other bearings.

MINING PROCESS.—No. 878,208. Jacob Kirschniok, Zabrze, Germany.



The process of cutting holes or slots in minerals which consists in directing one or more fine jets of water under a very high pressure against the mineral in the direction the hole or cut is desired.

DURABILITY OF ELECTRICAL APPARATUS.

Electrical apparatus, when well constructed, is well nigh indestructible if subjected only to the ordinary amount of wear and tear, and often comes out with flying colors from the devastating effects of flood and fire. The few incidents quoted below are excellent examples of the amount of hard usage that well constructed electrical apparatus will survive in working condition.

In the Knights Deep mine near Johannesburg, Transvaal, there were installed thirty-six 15 k.w. transformers and twelve three-phase 50 hp. G. E. induction motors for operating the pumps. Through a peculiar combination of circumstances the mine was allowed to fill with water, the motors and transformers remaining under several hundred feet of water for over two years. When taken out, three of the motors were re-wound in the local repair shop. The others were simply dried out and then soaked in oil. Contrary to expectations and to the surprise of all concerned, the insulation was found to be in excellent condition, and the motors were put into service, apparently none the worse for their high-pressure bath. The transformers were treated in the same manner, and shortly afterward they replaced several transformers of English make, which had burned out only a short time after being installed.

A railway power-station situated near the Mississippi river experienced a severe flood during the season of high water. Two 1500 kw. 6000-volt generators were more than half under water for nearly a week, but when dried carried their load without giving any trouble whatever. In fact, the first machine to be dried carried the entire railway load until the second machine could be put into condition.

A three horse-power induction motor was taken from the ruins of the printing office of *The Democrat* at Ellsworth, Maine, some few days after the entire building had been destroyed by fire. After being freed from the protecting coat of ice and cinders, the motor was dried and cleaned. When connected to the circuit it ran as smoothly as when first installed. Some idea of the intensity of the heat to which the motor was subjected may be gained from the fact that the switchboard and instruments were completely destroyed.

A 20 hp. 550-volt three-phase induction-motor, installed in a leather warehouse at Salem, Mass., was subjected to a severe ordeal during a fire. After the building and its contents had been deluged with water, the motor was removed, and after being cleaned, dried, and fitted with another pulley, started immediately on application of the current. The motor has since carried its rated load, and does not appear to be damaged in any way except as to appearance. Another excellent example of the durability of the induction-motor was shown by the remarkable performance of a 5-hp. motor used in driving a pump in the G. H. Perry Co.'s quarry in South Dakota. The motor was often allowed to run without any attention over night, especially during the rainy season. One night a heavy rainstorm filled the quarry to such a height that the motor was half under water. When started the next morning, it picked up its load and carried it steadily until the pit was emptied of water. On examination it was found to be none the worse for its prolonged bath, although a new pulley had to be put in place of the old one, which was softened and warped out of shape.

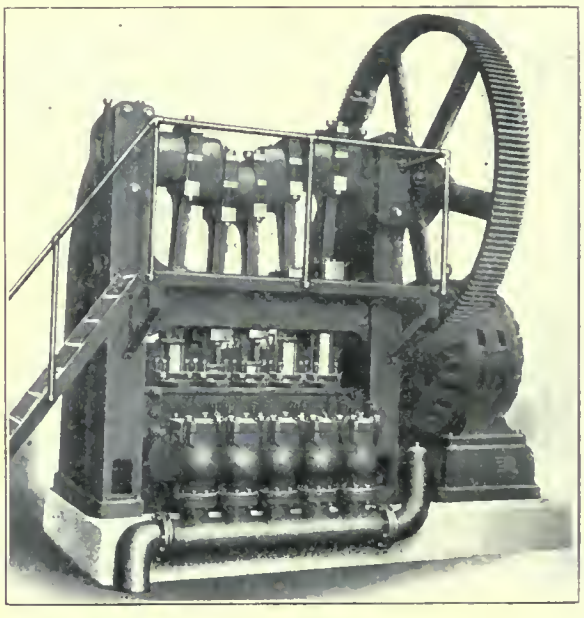
Several hundred General Electric flat-irons passed through the San Francisco fire, and aside from the fact that the wooden handle was destroyed and the iron slightly disfigured, the iron was as good as ever.

TRADE TREATISES.

The BALDWIN LOCOMOTIVE WORKS and the WESTINGHOUSE ELECTRIC & MFG. CO. have just issued a comprehensive catalogue of the electric locomotives for mine and industrial service manufactured jointly by these two concerns. The electric features of these well-known locomotives are the work of the Westinghouse Electric & Mfg. Co. and the mechanical features that of the Baldwin Locomotive Works. The numerous illustrations of typical installations show the extent to which locomotives of this make have been adopted. Among the illustrations is one of the testing plant in the Baldwin Locomotive Works, similar in construction to the highly successful testing plant in use at the St. Louis Exposition. This plant enables a complete record to be made of the performance of every locomotive before it leaves the works, thus determining positively just what may be expected of it under service conditions. Considerable space in the catalogue is devoted to the rating and performance of locomotives, and 'hour rating' and 'continuous capacity' are fully discussed. It is claimed that the Baldwin-Westinghouse locomotives are designed with particular reference to their 'continuous capacity,' experience having demonstrated that equipment thus rated is the least expensive for maintenance. The last two chapters are devoted to gathering locomotives and traction reel locomotives. The latter type is provided with a hooked steel cable, which winds about a vertical reel, driven by means of a small independent motor. A separate controller starts the reel-motor and the cars are hauled toward the locomotive, which itself remains stationary with brakes set.

ELECTRIC PUMP IN THE ANACONDA MINE.

An interesting electric pumping installation is being made by the Anaconda Copper Co. in its mines at Butte, Mont. The pump, which is illustrated herewith, is a 6 by 12 in. Aldrich vertical quintuplex type made by the Allentown Rolling Mills, Allentown, Pa., and is designed to deliver 425 gal. per min. against a head of 1100 ft. This pump is to be driven by a Westinghouse type CCL alternating current motor of 150 hp. capacity, at 450 r.p.m. The duty calls for heavy, substantial construction, and acid-



resisting material was required to be used in making the throat and plungers and other parts of the water end, on account of the bad condition of the mine-water that is to be handled. The use of five plungers operating from one crank-shaft, having connecting rods placed 72° apart, gives a uniform velocity of water in the pipes, thus adding greatly to the efficiency of the outfit.

The plungers are single-acting and outside packed. It is claimed that owing to the large size of the throats and valves and the comparatively low water-velocity through all the orifices, a high efficiency is obtained. This type of pump is becoming very popular in the Montana copper country by reason of its reliability and high efficiency, both of which are particularly important in mining operations, especially where power is purchased from transmission lines.

Editorial.

METAL PRICES are improving steadily and general conditions in business are becoming more cheerful. Locally there is a renewal of activity among operators, notably in quicksilver mining in Napa county and in copper mining in Calaveras and Shasta counties. In Nevada there is plenty of life and the wild-cat is coming out of the enforced hibernation that followed the panic. But there is lots of gold in Nevada, and even the wild-cats cannot kill the real mining and the sane business that are bringing that State to a leading position as a gold region.

ANOTHER district soon to be the scene of a mining excitement is Golden Circle, 52 miles northeast from Goleonda and about 42 miles in a similar direction from Battle Mountain, Nevada. An automobile stage line leaves both places daily, and 1000 people are already on the ground. The making of booms is much better understood than the making of mines: the first counts confidently on the greed of humankind, plus a generous allowance for the adventurous spirit, while the latter is compelled to overcome all the obstacles of Nature, the chances of fortune, and the cussedness of things in general.

COMPRESSED AIR has become so important a form of motive power that any elucidation of the principles involved is bound to be interesting. And no one is better fitted to expound this subject than Mr. Edward A. Rix. It is 30 years since he and his partners, W. H. and John B. Reynolds, brought the Ingersoll drill to the aid of Adolf Sutro in the making of the great adit that drained the Comstock lode, and it is 30 years since Mr. Rix took the same drill to the Idaho mine at Grass Valley and replaced the old Burleigh machines, which weighed 600 pounds apiece, as against, say, 275 pounds for a drill of equal utility today. The Burleigh had just made a record in the Hoosac tunnel, a railway bore in Massachusetts, where this first machine-drill was invented about 1872.

CALIFORNIA is so celebrated for her treasures of gold that most people overlook her wealth of copper. Yet this State produces 32,000,000 pounds of copper per annum. Most of this comes from a cluster of mines in Shasta county, but some of it comes from the foothill country flanking the Sierra Nevada, especially in the counties of Fresno, Calaveras, and Amador. It is a region that is destined to become more productive as the coal deposits of the Pacific Coast become better developed and a varied smelting industry is firmly established. An understanding of the geological conditions surrounding the occurrence of these copper deposits is neces-

sary to anyone wanting to exploit them, and this gives point to the valuable article by our friend Mr. John A. Reid, a young geologist who has given much energy and intelligence to the investigation of this region.

Theories of Ore Deposition.

ANY EDITOR would be pleased to give his readers such a contribution as that of Mr. Horace V. Winchell, in which that experienced geologist discusses the theory of ore deposition presented lately by Mr. J. E. Spurr. The letter from Mr. Winchell bears the marks of a man who has been underground in a copper mine, and, having doffed his overalls, has found a comfortable chair in a library rich in books of reference. The kindly humor and the philosophic banter suggest the highly civilizing effects of an excellent cigar, and if not that, then a good nature such as not even my Lady Nicotine need pacify. Assuredly we wish that discussion of Mr. Winchell's kind were forthcoming every week. His criticism is penetrating but polite; it is scientific, yet humane. We hope that other geological friends will be prompted to take their part in a controversy so pleasantly begun.

In the meanwhile it behooves Mr. Spurr to sharpen his pencil or dip his pen in illuminating ink, to the end that some obvious contradictions may be explained and some dark places made light. It looks like the old story of a generalization that failed to cover creation, and, like a carpet made for a small house, it became a shriveled-looking covering for the floor of a mansion. The edifice of knowledge is growing continually; it becomes broader and wider as the base of fundamental fact is enlarged, and it becomes more lofty as the intelligence of man is enriched by investigation. And yet we confess to a liking for the enthusiasm that provokes a geologist to risk his generalization on the strength of new evidence. Such leaders of thought carry a light into the cross-cuts that penetrate into new ground, and even though a blast of cold criticism may occasionally blow out the torch of a suggestive theory, we are grateful to the torch-bearer who has pioneered the way and stimulated enquiry. To come to concrete examples: It is safe to say that the debates on ore deposition associated with the names of Emmons, Posepny, and Van Hise did an immense service in sharpening the observation of geologists and in kindling the intelligent curiosity of all of those who go down the mine in skips. Then there was the memorable discussion before the Geological Society of Washington, in 1903, when Messrs. W. H. Weed and J. E. Spurr submitted a new classification that elicited a vigorous exchange of ideas. Such give and take of opinion, when accompanied by submission of the facts each man has collected in the course of his work as a geologist or an engineer, have a greater value than the single utterance of an individual, however eminent or learned, and it is astonishing how these discussions have enlisted the interest of people engaged in mining. The value of geology has been brought home to the untechnical and the application of science to industry has been much emphasized.

Only ignorant people sneer at theories. An impregnable theory is as much an impossibility as an impregnable armor-plate. There never was an armor-plate but there was, sooner or later, a gun that could smash it; and there never was a theory so flawless that it survived, unchanged and unharmed, the buffeting of the waves of Time and the artillery of ascertained facts. The man that expects to say the last word on a scientific problem is possessed of a splendid conceit; the man that is willing to stimulate thought by launching a working hypothesis is a benefactor, for even if his mental vessel must finally be wrecked, before its cruise is ended it will have sailed into unknown seas and carried a freight of understanding from one shore to another. All of us are compelled to theorize on insufficient knowledge, for even the youngest is not infallible. Each man covers a small area of observation, and his theories express the trend of his thought, as a tangent represents the direction of a curve over a small arc. But the tangent leads away from the curve; so also the theory, if followed with more enthusiasm than judgment, is likely to carry the observer away from his facts. We strike new tangents to fresh curves; we formulate new theories on the strength of fresh facts, and thus we avoid rushing too far into the limbo of supposition. Theories come and go, but knowledge widens. On the stepping stones of dead theories the geologist climbs slowly to the high summits of his science; he climbs, but never reaches the topmost crest; range after range is surmounted only to show range upon range beyond.

Mining and Metallurgical Societies.—II.

AMONG the societies organized in the interest of those who are engaged in mining, the American Mining Congress has achieved some prominence. Before arriving at any conclusion as regards the need of a new association, it will be well to enquire what the Congress has done and what it may hope to do. Founded eleven years ago, the American Mining Congress has had plenty of time to settle down to its chosen work. It was started as the International Mining Congress, but neither the membership nor the performance ever warranted a title so comprehensive. At its baptism it expressed the flamboyant expectations of the founders, a small clique whose avowed purpose was to stimulate popular agitation in favor of a Department of Mines at Washington. Annual conventions have been held, and as financial support was difficult to obtain, an appeal was made to different mining centres, successively; these furnished money and a transitory enthusiasm, in return for which the locality was generously 'boomed' by speeches, mineral displays, and a brief prominence in the daily press. This went on for a few years: then financial irregularities and mismanagement brought the International Mining Congress to the verge of ruin, so that, six years ago, it was resuscitated as the American Min-

ing Congress. Then, under a new management, it obtained a fresh lease of life, more vigorous and more sane. Mr. James H. Richards, of Boise, became president, and his friends became directors. They were assisted by a few mining engineers and geologists, who increased the prestige of the Congress by reading some excellent papers on technical subjects. The attendance at the annual conventions was improved thereby. But the Congress continued to be a complex institution, in part political, in part social, but also industrial and technical, while to such manifold activities there was always tied, like a tin can to the tail of this hybrid organism, a recurrent noisy effort to boom this or that mining district. Mr. Richards, a lawyer of wide experience and high character, has held together the diverse forces that give momentum to the undertaking, and it is to him and a small group of optimists that the organization owes its vitality. While it is true that the Congress is in the hands of a coterie, it is fair to add that but for the efforts of these few men the Congress would not have survived, nor is it apparent today that any other group would be willing to do the same work so persistently. For the Congress has not won any such measure of general support as was expected. Why? In the answer to this question lies the value of this enquiry as it affects the plans for a new organization.

Taxation without representation once received a historic protest, but representation without taxation is hardly less opposed to the logic of human affairs. This fundamental principle is transgressed by the Congress. It has never had a representative membership and it has never been placed on a respectable financial basis, because it is not supported by its own members. The list published in the last report shows 400 names, but of these 165 members are credited to Colorado, and bespeak the support given to the convention held at Denver in 1906. Members paid $631 in dues, while $835 was received from entrance fees, indicating the insignificant income derived directly from the rank and file of the organization. On the other hand, the City of Denver donated $1000 and the Chamber of Commerce in the same city collected $3500 more. This simply proves, as is well known, that the Congress is dependent upon the financial aid of the community in which its annual convention happens to be held, and, in return, the business of that community profits by the attendance of delegates and members from other parts of the country. While delegates cannot vote on the internal affairs of the Congress, they can take part in the proceedings, and as a matter of fact it is to them that the Congress looks for entertainment. Usually the most exciting event of each annual session is the choice of the place of next meeting; this involves a general debate, led by one or two orators, followed by impassioned speeches that evoke great enthusiasm. At the Denver convention there were about 250 delegates, of whom 150 represented the State in which the convention met. These delegates are nominated by Governors, Mayors, Chambers of Commerce, and so forth; the nomination means nothing, and not 10 per cent of those selected ever signify the least intention of accepting the appointment or of attending the Congress. In 1904 the President of the United States appointed three delegates (of whom one attended the Portland meeting), and in 1905 he requested the Director of the Geological Survey to select a larger number; those chosen finally received a letter signed by the Chief Clerk of the Survey, so that the whole thing descended into a formal absurdity. Thus, both as to membership and delegation, the Mining Congress fails to be in the least representative. Therein lies its failure.

And yet it has not utterly failed, for the Congress has held forth in advocacy of a Federal Department of Mines, and it deserves credit for having finally prompted legislation on this subject. Yet it looks now as if all the effort made were to end in a mere enlargement of the technological branch of the Survey. This result is not devoid of humor. It is to the members of the Survey that the meetings of the Congress have owed much of their interest, for the Government geologists have read papers of more than local interest, and their addresses on the waste of natural resources, on mine accidents, and on kindred subjects, have given the conventions a national character and a dignity much needed. It has been obvious to the onlooker that the policy of the Director of the Survey has been to recognize the Congress and steer its course in matters affecting the welfare of the Survey. For its success the Director may be complimented; and this refers to both Mr. Charles D. Walcott and Mr. George Otis Smith. Now that the Mining Department question is practically shelved, the Mining Congress has lost one of the chief stimulants to its vitality, and is likely to devote itself to voicing the grievances of mine operators against the smelting corporations, to advocating measures for the prevention of fraud in mining, and to other subjects of public interest. But as long as it remains in the hands of a coterie of mixed character, as long as its membership is neither representative nor self-supporting, and as long as it is at the mercy of local 'boosters,' it will accomplish no useful purpose. To be a force in the country, the Congress must depend neither upon mine promoters nor hotel-keepers, and it must be shorn of its appendages, such as the reading of technical papers. The mixed audience that the Congress affords is not fitted for the consideration of technical questions; no useful scientific discussion is possible before a nondescript gathering, agitated by cross-currents of a political nature. Some excellent papers that ought to have appeared in the transactions of technical institutions, have been entombed amid the oratorical confectionery of Mr. Josephs of Utah or Mr. Lafe Pence of Colorado. As an organ of public opinion the Congress may have a useful function to perform, but as it is now constituted it suffers from numerous adhesions of a debilitating character. A surgical operation seems necessary, followed by adequate sustenance from a vigorous body of self-supporting membership. Whether it will survive such capital treatment may be doubted; it may prove one of those highly successful operations that please the surgeons while killing the patient, but it is also the only one likely to preserve his life.

Personal.

ALFRED JAMES is in Mexico.

W. J. LORING is expected in London.

JOHN B. FARISH is in Sonora, Mexico.

LEO VON ROSENBERG was at St. Louis lately.

HAROLD RICKARD is on his way to Guatemala.

R. S. RAINSFORD, of Salt Lake, is at New York.

JOHN R. FARRELL is now living in San Francisco.

P. R. BRADLEY is at New York, from British Guiana.

RUPERT C. ALABASTER is at Cloncurry, In Queensland.

M. PARRY GOSSET is now at Tominil, in Durango, Mexico.

R. STUART BROWNE has returned to San Francisco from Mexico.

CHARLES BUTTERS has returned to San Francisco, from Mexico.

DONALD FERGUSON, of Goldfield, Nevada, is here on a short holiday.

CHARLES L. TUTT, of Colorado Springs, is at the St. Francis hotel.

C. E. ARNOLD is working in the Hoatson shaft, at Bisbee, Arizona.

C. J. KENNEDY, of Seattle, was here on a visit from the Comstock.

JOHN A. PORTER has returned to Denver, from San Jose, California.

A. CHESTER BEATTY has been taking a few days holiday in Bermuda.

W. G. SCOTT, foreman with the Arizona Copper Co., is here from Morenci.

FRANK LAWRENCE has returned from Australia, on his way to Colorado.

H. W. HARDINGE has gone to southern Nevada and expects to visit Rawhide.

MARTIN J. HELLER has moved his office to 43 Exchange Place, New York.

WILLIAM DE L. BENEDICT is on his way back to New York, from San Francisco.

FREDERICK S. HARRIS is ill of typhoid fever at the Agnew Sanitarium, San Diego, California.

LOUIS JANIN came from his farm near Santa Barbara, and remained in San Francisco for a few days.

MARK R. LAMB, formerly with Charles Butters & Co., is now with the Moore Filter Co., of New York.

GEORGE A. SCHROTER, consulting engineer to the Creston Colorada Co., in Sonora, is now at Los Angeles.

FRANK A. KEITH has resigned as manager for the Tonopah Mining Co., owing to pressure of private business.

O. M. PUDOR, lately general manager for the Texas-Nevada Gold Mining Co., of Olinghouse, Nevada, has gone to Rawhide.

W. S. WARD has been appointed director of the department of art and minerals in the Colorado Museum of Natural History, at Denver.

P. T. FARNSWORTH has resigned as manager of the Horn Silver mine, in Utah. He has been succeeded by M. C. MORRIS, formerly assistant secretary of the company.

J. E. SPURR has gone to Matehnala, San Luis Potosi, Mexico, to make a geological examination of the Cobriza mine for its owners, the Compañia Metallurgica Nacional.

HOWARD P. SAUNDERS, of Salt Lake, is examining the Nevada Superior mines, at Humboldt, and then he will go to Cherry Creek, also in Nevada, to supervise the construction of the new stamp-mill of the Cocomongo Gold Mining Company.

DIVIDEND.

The Minas Pedrazzini Co., of San Francisco, has declared dividend No. 4 extra, payable April 1, and the regular No. 5 of 2½%, payable May 15.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Maggie vein on United Globe ground has been struck in the north cross-cut from B shaft on the tenth level of the Old Dominion ground. Sulphide vein No. 1 was struck on the 15th level from the winze to the 16th. The Maggie vein was struck at a distance of 850 ft. from B shaft, and although the vein has been cut for only a few feet, the ore disclosed so far is of high grade. Sulphide vein No. 1 was struck on the 15th level, 95 ft. from the winze, and the full breast in the cross-cut is in ore. The grade of the ore is similar to that on the foot-wall of the vein on the 16th level running low in copper and high in sulphur. The diagonal cross-cut driven from the main cross-cut on the 5th level of the Great Eastern mine of the Superior & Boston to intersect the Black Hawk vein at a point 40 ft. west of where the vein was first struck, has now penetrated the vein, but has not yet cut through it. This proves up the Black Hawk vein for a length of 220 ft. on Great Eastern ground. The drift which is being driven from the Black Hawk mine along the vein is now 100 ft. into the Superior & Boston ground, with no apparent change in the character of the ore.——The first consignment of the new pumps to be installed on the 1000-ft. level of the Big Shaft of the Tombstone Con. Co., consisting of three car-loads, has arrived. The new pump will complete an installation of a daily capacity of 10,000,000 gal. The quantity of water at present raised is about half that amount.——At the Emerald mine satisfactory developments are being made. The winze that is being sunk from the 800-ft. level is in ore, the limits of which have not yet been determined.

GILA COUNTY.

The discovery of a low-grade copper deposit is reported from the district on the old Mineral Park Chloride wagon-road about ¾ mile from the Western Railway of Arizona. Carbonate of copper is found impregnating a breccia, but little development work has been done. The deposit is below the limestone on Nigger Head Mtn.——The labor troubles between the Warrior Copper Co. and the Globe miners' union have been settled.——The annual meeting of the stockholders of the Octave Mining Co. was recently held in Phoenix. The report showed the mine to be in excellent condition, with over 268,000 tons of ore blocked out, assaying about $8 per ton. As soon as the ore reserves justify enlargement, additional stamps will be erected and an electric power-plant installed.

GRAHAM COUNTY.

The New England & Clifton Copper Co., which recently resumed operations, is now making regular shipments of ore to the Shannon smelter. The double-compartment shaft at the Antietam has been straightened and will soon be completed. From the mines in the upper part of the district shipments are made daily over the tram-road recently built by the company. A new air-compressor has been shipped to the Antietam mine and shipments will soon be increased.——At the Copper King mine development is progressing well, and 25 tons of ore are shipped daily.——The New York-Arizona Co. will soon erect a 10-stamp mill, as sufficient milling ore is now blocked out to justify the expense.——Ore has been found in a cross-cut on the 1200-ft. level of the Gem shaft of the Globe Con. Co. A 2-ft. vein was encountered in the north cross-cut at 330 ft. from the shaft. The cross-cut will be continued 150 ft. farther, where it should encounter the Future vein. This vein was barren on the 500-ft. level, though well defined walls were found, between which vein-stuff 22 ft. wide occurred.——Rich ore has been found on the Iron Cap mine of the National Mining Exploration Co. Six feet of high-grade carbonate ore was found in the west drift on the 460-ft. level.

SANTA CRUZ COUNTY.

A 30-ton smelter will be erected at the Mansfield mine. J. A. Traylor, of the Traylor Machinery Co., is consulting engineer to the company.

YAVAPAI COUNTY.

W. A. Robinson and J. Kennedy, who have a lease on the Samoan mine at Chloride, have 37 tons of ore on the dump ready for shipment to the smelter.——The mill which is being erected by the Yucca Clanide Mining & Milling Co. near Cedar is nearly completed.——A stringer of rich ore has been found by J. H. Haas on his claim south of the Keystone, Mineral Park.——At the Bullwhacker mine, situated 3 miles east of Prescott, rich ore has been found on the 60-ft. level.

YUMA COUNTY.

At the Colonial Mining Co.'s plant in the Weaver mining district, near Ehrenburg, ore is now being run through the 36-ton quicksilver furnace. The ore is broken down in the stopes, sorted and run into mill-holes, the waste from the mine being used for filling. From chutes at the bottom of the mill-holes the ore is trammed to shaft-pockets, from

Map of Arizona.

which a self-dumping skip is filled, hoisted to the top of a head-frame, and dumped over a grizzly, the fines falling into a 100-ton bin, the coarse going to a crusher, after which it goes, together with the fines, to the furnace bin.

CALIFORNIA.

EL DORADO COUNTY.

At the Woodside-Eureka mines, the work of grading for the foundations of the head-frame and hoisting-engine at the old Eureka shaft will be begun shortly. The old shaft is 240-ft. deep. One of the new 60-hp. boilers and hoisting-engines will be moved from the new 3-compartment shaft 600 ft. south, to the old shaft, and after unwatering the old workings, several hundred tons of the ore now exposed in the lower workings will be extracted, and development carried down to 70 ft. below the present lowest level.——It is reported that a shoot of high-grade ore has been found on patented land, between the Taylor and the Argonaut mines, on the Collins ranch.——Sinking has been resumed at the Little Chief mine and a pump has been installed.——Lumber is being hauled to the Gilbert mine for surface improvements, and development work is progressing.——The Green Valley Mining Co., which is operating on a gold-bearing channel in the Dormody ranch, has installed an elevator, actuated by a gasoline engine. This supplies water under pressure to run the gravel down from 8 to 15 ft. into sluices.——At the Clipper mine in the Georgetown district, preparations are under way to commence sinking the shaft to the 500-ft. level.——At the Collins-Bacchi mine

work will soon be commenced on the new shaft.——At Craddock's mine in the Canyon, the cross-cut adit has struck the Smith and Kohn vein. Drifting will now be begun both ways.

NEVADA COUNTY.

(Special Correspondence).—The adit at the Posey Canyon has reached a point below the channel. A raise is being driven to tap the gravel.——The shaft at the Bessie mine is down 200 ft. in ore. Considerable ore is on the dump and the company is arranging for the installation of a stamp-mill. Byron Burgiss is superintendent.——A good body of ore has been struck in the south drift in the Gold Mound mine at a depth of 150 ft. An 8-ft. vein of good grade milling ore is being developed. The shaft will be sunk to a depth of 800 ft. as rapidly as conditions permit. Howard P. Dennis is superintendent.——The Kenosha shaft is rapidly going down. High-grade ore continues to come from the vicinity of the 300 level.——Extensive development work is under way in the lower workings of the North Star mines. Eighty stamps are constantly falling on good ore.——Work has been abandoned at the old Malakoff mine and the track and underground supplies removed.——Owing to deep snows at the scene of operations, the Anchu mine has suspended work until warm weather sets in.—— The orebody recently encountered in the west drift on the 1000-ft. level in the Murchie mine continues to show well with development. Preliminary work on the sinking of the shaft 200 ft. will commence at an early date.——At the Oustomah considerable exploration and development work is going on. Good ore has been blocked out at several points.——Promising bodies of ore are being developed in the Golden Gate. Much of the ore is high grade. W. P. Martin and associates are working the mine under a lease. ——Robert Johnson has developed the antimony vein on his ranch for a considerable distance. Tests of the ore show good percentages of antimony, with small quantities of other valuable metals.——The shaft at the Normandie is going down steadily, and it is expected that the main veins will soon be intersected. Several men are employed. ——Bray Wilkins states that his company is prepared to work the Idaho-Maryland mine on a large scale. The rich vein recently encountered on the 500 level continues to show splendidly. Ten stamps are running on ore coming from this vein.——Several claims have been recently located in the Bloomfield district and notices filed with the County Recorder.——Reports continue to be circulated to the effect that work at the Conlan mine will soon start.—— The two veins under development in the Union Hill are showing well. A fair tonnage of ore has been blocked out. ——Representatives of Eastern mining interests have been examining properties in the Grass Valley-Nevada City district with a view to their acquisition.——Local mine operators are said to be heavily interested in the company which recently purchased the Mason and adjoining ranches, below the city, for mining purposes.

Grass Valley, March 16.

PLACER COUNTY.

The water has been pumped out of the Mountain Gate mine and gravel is being extracted. The ground will be worked through the Hidden Treasure adit.——The Homestake mine at Last Chance is being operated by R. L. Fletcher. A mill will be erected as soon as the snow is off. Much of the gravel is cemented and requires milling, but it is of good grade. The Slope, Wasson, and Blackhawk mines will also be worked under the same management through the Paragon adit.

SHASTA COUNTY.

The improvements at the Kennett smelter of the Mammoth Copper Co. have been nearly finished, and the two new blast-furnaces and two converter-stands are now in operation. The blast-furnaces are 50 by 180 in., with water-jacketed tops and settlers of 16 ft. diam. and an intermittent tap. About 1300 tons of crude ore will be treated and the matte re-melted in a blast-furnace before it passes to the converters. The new converter building has two converter stands and eight shells, 96 by 150 in. The converter building is served by two Morgan electric overhead cranes of 50-ft. span and a main hoist of 50 tons capacity, with two subsidiary hoists of 15 tons each. In the power-house four Connersville blowers have been added, and also a converter blowing engine of 10,000 cu. ft. capacity at 15 lb. per sq. in., driven by a 750-hp. G. E. motor. A relining plant for the converters is equipped with two pneumatic tapping machines of the Ingersoll-Rand pattern. A new dust-chamber and steel stack 200 ft. high and 18 ft. diam. has been erected for the blast furnaces, and the old one will be used for the converter plant.

COLORADO.

CLEAR CREEK COUNTY.

Work will soon be resumed on the old Georgetown adit, the portal of which is on Columbia Mtn., by the Georgetown Mining, Power & Tunnel Co. It is the intention of this company to drive the adit 6000 ft. and tap the mines in Democrat Mtn. The adit will be 8 by 8 ft. in the clear. ——The Charter-Raton Mining & Milling Co. is driving the La Moe tunnel on Breckenridge Mtn. The tunnel has been advanced 950 ft.——A rich streak of ore from 6 to 10 in. wide has been found in the Sporting Times mine on Griffith and Alpine Mtn.——The machinery at the Mendota mill, being operated by the Mendota Mines Co., has been started up after repairs. Three shifts will be worked and lead, zinc, and iron concentrates will be shipped. The plant will treat dumps and some ore left in the old stopes above the Victoria tunnel level. The mill has a capacity of 25 tons per day.——The Shively cross-cut adit is being driven with Temple electric drills. This will cut the Shively shaft at the 500-ft. station.——Rich shoots of ore have recently been found at the Capital mine. In the west drift on the Aetna vein a rich orebody has been found, but its size has not yet been determined. The 100-ton mill is running steadily, and a night shift will soon be put on.

GUNNISON COUNTY.

Richards & Co., who recently took a lease and bond on the War Dance and War Dance extension claims in lower Willis gulch in the Russell district, have struck high-grade ore in driving at a depth of 140 ft. Lessees have taken out several tons and expect to make a record shipment to the sampling works. The strike was made on the War Dance, which is down a depth of 140 ft.——It is reported that a discovery has been made in the Jumbo adit, situated on the east side of Jenny Lind gulch and near Boulder Park. The adit is now in a distance of 700 ft., and the vein just opened is reported to be 20 ft. wide.——The Champion Mining & Milling Co., operating in the Phoenix district, is getting out some ore at its Lone Star mine, where work is being done at a depth of about 250 ft. The company is arranging for the deepening of the shaft.——The work of unwatering the Paoli mine in Leavenworth gulch is progressing favorably, the water now being down below the first level, where they have some good ore. The main shaft is down 220 ft., and as soon as unwatered and re-timbered wherever necessary, the lessees will sink as well as carry on considerable drifting work. Machinery has been installed and the surface buildings are to be painted.——A shipment of 30 tons of smelting ore was made from the upper workings of the Two-Forty property in Willis gulch recently to the Argo smelter, which gave returns of about $20 per ton. The property is being worked by lessees.

SAN JUAN COUNTY.

The Auburn Con. Mining Co. will start active development as soon as the weather improves. A new 25 kw. transformer will be installed for use with the Temple electric drills, and a new mill will be commenced as soon as the adit reaches the vein.——Ten men are steadily engaged in driving the tunnel on the Bullion King mine. High-grade ore has recently been found.——At the San Antonio mine at Red Mountain work will soon be actively resumed, and a deep level adit commenced. This will be started near the Junction, and will cut the veins at a depth of 600 ft. when 3150 ft. in length. The adit on the Camp Robber group will also be extended to the orebodies, which will

cut them at 250 ft. below the surface, and the Salem adit will be driven 600 ft. forward to open up unexplored ground. At the Carbon Lake mine the shaft will be unwatered and sinking will be resumed. At present the shaft is only 200 ft. deep, and there is less than 500 ft. of drifting and cross-cutting. The ore formerly mined averaged $21 per ton.

TELLER COUNTY.

Active development work is progressing on the property of the Michorado Gold Mining Co. on Iron Clad hill. On the Seven-Thirty claim, adjoining the Forest Queen, a contract has been let for the sinking of the shaft to the 250-ft. level. The shaft is now at a depth of 190 ft. and several stringers of good ore have been encountered. A station will be cut at the 200-ft. level and a drift started on the vein.——The Summit claim, owned by this company, situated near the Ironclad mill, is leased to G. E. Walcott for two years. A shaft, 8 by 8 in the clear, is being sunk, and is now 30 ft. deep.——The Pride of Cripple Creek Leasing Co., operating on Iron Clad hill, has shipped a car-load of $25 ore, which was stoped from a 3-ft. vein on the 560-ft. level.——The Little Ciara Leasing Co., operating on the south end of the Little Ciara through the Ophelia tunnel, is reported to have worked the main No. 45 vein up to the side line of the Lucky Corner claim of the Doctor-Jack Pot Co. The same parties, the Humphreys-Thompson lease partnership, are also reported to be sinking the shaft on the Callie claim of the Stratton estate. This shaft, now 675 ft. deep, is reported entering another flat formation, the assays taken taken from the vein recently disclosed being low. With an additional depth of 25 ft., cross-cuts are to be carried east into the Little Ciara and west into the Morning Glory No. 4. On the middle block of the Little Ciara, under lease to the Union Leasing Co., development work is in progress, but shipping ore has not been encountered to date. The Work company directorate at its last meeting in February declared a dividend of $15,000 and the distribution will be made on April 4. The company has paid to date $165,000.

A petition was filed in the district Court yesterday by the Franklin Mining Co., asking for a writ of injunction to restrain the Gold Sovereign Mining & Tunnel Co. from interfering with the shipment of ore by the plaintiff. It is alleged in the complaint that the defendant company is seeking to coerce the plaintiff to ship its ore to the United States Reduction & Refining Co., in spite of the contract existing to ship it to the Golden Cycle Co. It sets forth that on Dec. 19, 1907, the defendant leased to Albert Lewin the property known as the Gold Sovereign and James G. Blaine lode mining claims, survey 8600, and the same day Lewin assigned the lease to the plaintiff for three years. It is alleged that an understanding existed with the defendant that all ore should be shipped to the Golden Cycle Co., and that a contract for three years was made with such company. Now it is charged that the defendant wants the ore shipped to the United States Reduction & Refining Co., claiming it has made some agreement with this company. Plaintiff insists that it is a trick to cause plaintiff to violate its contract, so that the lease can be declared forfeited. It is further charged that the defendant has issued orders to the railroads to ship all ore from the mines to the United States Reduction & Refining Co., and that the railroads are holding the ore, at great loss to the plaintiff, pending court action. A writ of injunction is asked and also damages. An interesting feature in connection with the litigation between the Franklin and the Gold Sovereign companies is the fact that there are now 11 cars of ore tied up because of having been ordered to different mills by the rival litigants. While the disposition of this ore is awaiting settlement by the courts the railroads are charging $2 a day demurrage on each car.

Lessees on the Sitting Bull claim of the Keystone Mining & Milling Co., situated on Bull hill, have shipped four carloads of ore assaying $30 per ton. A vein 3 ft. wide has been opened up and drifting on the ore is now in progress at an approximate depth of 300 ft.——The Columbia Mining & Leasing Co., operating on the Chicken Hawk claim of the Katinka company, has more ore extracted than can be shipped with the present facilities. The ore assays $25 per ton, and a good sized body has been found on the 700-ft. level. The company is also doing some development work by extending the cross-cuts to the north and west to cut veins which are believed to traverse the property, as they have been explored on the adjoining Doctor-Jack Pot claim.

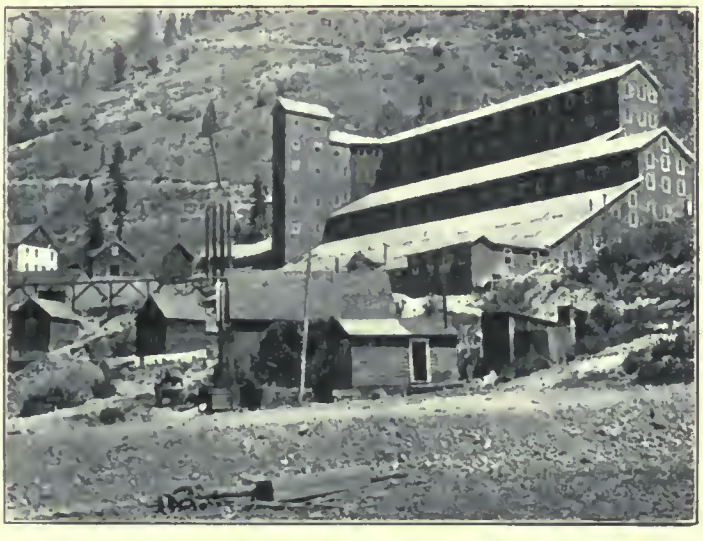
IDAHO.

IDAHO COUNTY.

The work on the 300-ft. station of the Buster mine has been completed and sinking resumed. About 30 men are employed and the mill was completed in December.

LATAH COUNTY.

(Special Correspondence).—Much activity is anticipated in the Hoodoo district during the coming season. The last consignment of machinery for the Mountain Gulch Mining Co. has arrived at Harvard, and as soon as snow has melted sufficiently, it will be taken to the mines. Millwrights will be sent to put in foundations, etc., within a short time. A two-stamp mill is already on the property, and a Huntington mill is among the new machinery added this season. ——The Mizpah Copper Mining Co. will begin development at once by raising from the No. 3 adit to a 50-ft. shaft, which will open up 200 ft. of ore. This ore is cuprite, malachite, and azurite, and is of high grade. It is said that with the completion of this raise the company will be ready to ship ore. Estimates have been received for an aerial tramway 200 ft. in length to the railway. The Washington, Idaho, & Montana railway has graded to within this distance of the mine, and has given assurance that as soon as a sufficient tonnage is secured, track-laying will be started.



Smuggler-Union Mill Near Telluride, Colorado

Spokane, March 4.

NEZ PERCE COUNTY.

(Special Correspondence).—The Orogrande Placer Mining Co. has been incorporated in Spokane by a number of Idaho and Washington men, and will begin working the rich gravel deposits of the Pierce City district as soon as the snow is off this spring. The incorporators are: W. H. Stole, W. S. Willis, W. O. Jones, R. D. Cleek, C. E. Horton, H. T. Madgwick, and Bedford Brown. The territory to be worked consists of 12 claims in the Orogrande creek bottoms, near the mouth of Rhoades creek. The ground is composed of boulders and fine sand, over which a growth of willows has spread. It will be worked by a Rubel elevator. A machine of this type operated for the past two

years by J. H. Porter has given excellent results, and it is said that ground carrying ten cents in gold can be profitably worked. The work of clearing the land and digging the ditch will be commenced by R. D. Cleek as soon as possible, and it is hoped to be washing gravel by August.——The Ozark Mining & Milling Co. has bought an air-compressor, power-drills, etc., and will erect them at the Wild Rose adit at once. This is the first power machinery ever taken into the Pierce City district. The company has been carrying on development work all the winter, but will now increase its force. Work is being concentrated on the 1200-ft. tunnel, which is to cross-cut the main lode, and the Ozark group is lying idle. From surface indications it is thought there are several smaller parallel veins which will be cut by the tunnel. Work has now progressed 150 ft.——A number of other companies are preparing for spring work, and within a short time dredges and elevators will begin.

Spokane, March 14.

SHOSHONE COUNTY.

The Snowstorm mine is shipping 100 tons of ore per day, and an increased output will soon be made. The ore is shipped to Tacoma, and the Granby smelters at Grand Forks and Great Falls. The Leslie mine has been unable to run its compressor, owing to the snow, which is 11 ft. deep. The water to run the machinery is now collecting in the reservoir, and operations will soon be resumed. About 6600 ft. of development work has been done, and it is expected that the vein will be struck by driving 50 ft. farther at a depth of 1100 ft. below the outcrop.——A tunnel is being driven on the Buffalo mine by contract. The tunnel is to be 1300 ft. long and will strike the main vein at 900 ft. and at a depth of 700 ft. When the vein is struck drifting will begin both ways.——The Rex mine is shipping ore regularly, the lead concentrate being sent to the smelter at East Helena, and the zinc product being stored until the market improves.

NEVADA.

ELKO COUNTY.

Gold Circle is about 35 miles from Battle Mtn. and about 47 miles from Golconda. It can be reached by automobile from either point, although it is handier now from Golconda, whence one may travel to the camp in three and a half hours. At present a road is being surveyed from Battle Mountain, and six regular autos and two stage lines are running form Golconda.——There are two town-sites, Midas and Summit, about a mile distant, which have been consolidated within the past few days under the direction of one corporation. At present the camp contains approximately 300 inhabitants, with newcomers arriving at the rate of 25 to 30 per day. Since the first discovery, which was made on the Bamberger claim some time in September last, little work has been done on account of snow, but with its disappearance, conditions are rapidly improving. Natural conditions are good, water being right on the ground in Midas, and water rights have been taken up in Summit, where the stream is said to be capable of generating nearly 1000 hp. for electrical power. The Bamberger strike, within 10 ft. of the surface, is perhaps the best yet uncovered. The Spotted Dog claim is also good, and the Esmeralda, four miles distant, shows the extent of the good territory. The Elko Prince has an adit driven in a distance of 100 ft. and is in good ore, while the St. Paul shaft is down 40 ft. The best ore is a very close-grained rock caller jasper, in which it is impossible to see free gold, but which pans most satisfactorily. At Golconda the hotel accommodations are good. All trains except the Limited stop there, and transportation is an easy matter.

ESMERALDA COUNTY.

A vein has been discovered on the 1250-ft. level of the North Star mine, which is more than six feet in width. The ore was found in a cross-cut 560 ft. north of the shaft, and is similar to that in the other important mines of the camp. This discovery is as deep as any workings at Tonopah, and would correspond to a depth of 1000 ft. below the collar of the Montana-Tonopah mine.——A 44-hp. hoist has been ordered by the Buckeye-Tonopah Mining Co., and sinking resumed. The shaft is now 275 ft. in depth. Four machine-drills and a compressor will also be installed.

A new find is reported at Lorena, a camp situated 18 miles southwest of Rawhide, on the road from Mina. High-grade ore is said to occur, and a boom has been started.——The control of the Combination Fraction is supposed to have passed to Goldfield Con. interests. The property is being worked and three car-loads a week averaging $70 per ton are being shipped. Daisy is developing excellent ore. The work is being done in shaft No. 1, and a raise is being driven from the 210-ft. level on ore that assays over $100 per ton. In addition to 3 ft. of shipping ore, a wide vein of milling ore occurs. The material for the Consolidated mill is arriving, and it is hoped that the construction will be finished by Sept. 1.

HUMBOLDT COUNTY.

(Special Correspondence).—A 10-stamp mill is to be built at the Mazuma Hill mine in Seven Troughs district. J. Hill of Lovelock is managing the property. He states that the ore is free-milling and most of the gold will be saved on the plates, though concentrating tables will also be erected. The machinery will be operated by a gasoline engine. The mine is opened by adits and by a shaft that was sunk from the lowest level.——The Kindergarten M. Co. is erecting a 10-stamp mill in Seven Troughs, which will be run by a gasoline engine. L. A. Friedman and J. Knight of Utah are interested in this property.——The Nevada United Mines Co., managed by J. T. Read, has been developing a prospect for some time in East range, 30 miles southeast of Lovelock. For the purpose of cutting a well known copper lode at about 1000 ft. depth, a long cross-cut is being driven. It is now in 1500 ft. and the lode will be intersected at approximately 2100 ft. from the portal. The cross-cutting is being done with air-drills, the compressor being steam-driven.——The Chase-Andrews Co. of New York is erecting a 100-ton concentrator four miles from Lovelock to handle the antimonial ores from the mine of the American Antimony Co., situated 14 miles from Lovelock. This mine is well developed to a depth of 400 ft. The mill is to be equipped with jigs, and is situated on the Humboldt river.——The mine and mill of the Bonanza King M. Co., which have been idle some time, are expected to resume operations this spring. The ore there carries gold and silver, and the mill has 15 stamps and four tables. The property is 30 miles out of Lovelock.——The Jessup district is described by J. T. Nagel as being 30 miles southwest of Lovelock, in a country of porphyry and rhyolite. Jessup peak, a landmark of that section, rises to an altitude of 7500 ft., the surrounding plateau being at an elevation of 3500 ft. The first discoveries of gold were made by Jessup and Murray last January in the lower hills of the plateau. The ore is in quartz veins, accompanied by talc. Some of the veins are at the contact of phonolite and porphyry. Mr. Nenzel, who lives in the district, states that considerable work is in progress by lessees.

Lovelock, March 14.

LINCOLN COUNTY.

One of the most important developments in this district for some time is the beginning of operations on the 5000-ft. tunnel from the Day mine, of the Nevada-Utah Co., through the mountain to the Bristol side. By means of this tunnel a highly mineralized district on the other side of the mountain is made accessible. There are several properties of promise in addition to the Bristol mine which will be affected. It is understood that the Bristol property has been taken over by the Nevada-Utah interests.——In the Columbus-Pioche, situated near the Half Moon, about 2½ miles from the town, has recently been opened a large body of silver-manganese ore similar in character to that of the Black Prince mine. The vein has been stripped for 60 ft., and on account of its desirable fluxing quality is a body of unusual promise.——The Ploche-Demijohn Co., while sinking its shaft recently, encountered a body of rich ore.——The Lincoln-Nevada Co. is below the 200-ft. level with its shaft. A station is being cut at the 200 level, where a 12-ft. vein of ore exists. Preparations are being made to stope

and ship ore, some of which is said to be of high grade. The shaft has been in ore all the way down.——The California-Pioche Con. Mining Co., which owns four claims adjoining the Ohio-Kentucky and Nevada-Utah, has just erected a 40-ft. head-frame, and is sinking a two-compartment shaft to develop its property, which contains an extension of the vein that the Ohio-Kentucky is working. This vein has every appearance of being of value, and can be traced from the Ohio-Kentucky lines almost a claim length. It is the intention of the company to sink 300 ft. and cross-cut to the vein.——The Prince Con. mine is opening up well under the vigorous development campaign being carried on there.

NYE COUNTY.

A rich stringer has been found on the Riggs-Forman lease on the Earl ground, on Litigation hill. The high-grade ore is being sacked from a streak about four inches wide on the side of a vein from one to three feet wide.——A mill will be erected to treat the ores from the Solid Gold lease on the property of the Round Mountain Daisy mine. The vein is 5 ft. wide and assays about $25 per ton.——The M. & M. lease is stoping ore, which will be treated in the custom mill at Round Mountain as soon as it is completed. A raise from the 90-ft. level has penetrated a vein 4½ ft. wide for 20 ft. A cross-cut on the 140 level has struck a new vein north of the main shaft, averaging $12 per ton. ——The Atchison Leasing Co. on the Round Mountain Combination has been sinking in ore from the surface. The shaft is now down 35 ft. A gasoline hoist will soon be installed.

STOREY COUNTY.

(Special Correspondence).—The Selby Con. M. & M. Co., managed by Emerson Gee of Reno, has performed 1000 ft. of work on its property three miles from Virginia City. The ore carries gold, and the company announces that a mill will be erected within the next few months.

Virginia City, March 16.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Black Tail group of four claims, lying contiguous to the Lone Pine group, which the Syndicated Deep Mines Co. is working, has been taken on a working bond by J. E. McFarland, and will probably be operated in conjunction with the latter. A crew of men will be put to work shortly. The Black Tail group was a shipper in the early days of the Republic camp, when it sent 377 tons to the Granby smelter which averaged $18 in gold and silver. Another lot, put through the old Republic mill, ran about $14 to the ton. Since the collapse of the Republic mill this property has lain idle. This is the third group to become active within the last three months, and seems to indicate that the Republic district is to become a mining centre again. The Lone Pine has shipped two cars of ore, stoping having been begun about three weeks ago.

Spokane, March 13.

SNOHOMISH COUNTY.

At the Index-Bornite mine a 4-ft. vein with a pay-streak of rich copper ore has been found in the lowest adit. Driving on the vein has proved the vein for 34 ft. A shaft 70 ft. deep was formerly sunk on the vein and some rich copper ore obtained, but the present workings have developed the vein at greater depth. This property is three miles up the river from Index, and will be within half a mile of the proposed Index-Trout Creek railroad.——Development work is progressing on the Tillicum claims. An open cut has been made on the vein about 500 yd. from the county road, and copper and molybdenite ores discovered. The claims are now to be developed by an adit driven on the vein, which is now 125 ft. in length. This must be driven 75 ft. farther before the old workings will be reached.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—Rumors of a gold strike of importance in the Le Roi mine, near Rossland, were confirmed March 11 by Andrew Larson, the superintendent, who admitted that a rich find had been made. The ore was found at the 1650-ft. level, where a cross-cut had been run from the main lode to tap the south lode. The gold runs from $5 to $40, and small shoots have gone as high as 5 oz. This is considered to prove the south lode in depth, which had been worked out above the 900-ft. level. A diamond-drill hole driven on the 900-ft. level a distance of 800 ft. to tap this same lode to the east, led to the driving of a cross-cut tunnel, which is now also in high-grade ore. This seems to prove the eastward extension of the south lode, which had been found barren as stoping progressed east. There have been no smelter returns as yet on this gold ore, as the company will ship it separately from the regular output.

Rossland, March 13.

(Special Correspondence).—The shipments of silver ore from the Cobalt camp last week were: Nipissing, 64.35 tons; La Rose, 45.09; O'Brien, 32.55; Coniagas, 30.94; Kerr Lake, 33.085; Temiskaming & Hudson Bay, 30; Silver Queen, 26.85; Nova Scotia, 20; Cobalt Central, 24.7 tons. The latter shipment consisted of a car of concentrates. According to the returns of the Dominion Government, the total silver production of Canada for 1907 amounted to 12,750,044 oz. of refined silver, valued at $8,000,000, of which the Cobalt camp produced about $6,500,000. It is estimated that this production will be doubled in the present year, as several of the big properties, among which is Cobalt Central, have only begun shipping regularly since the first of the year.——As the result of diamond-drill tests, the Silver Queen has decided to continue its main shaft to a depth of 400 ft. The Cobalt Central mines are also rapidly deepening their main shaft on the Big Pete property. The lowest level in the mine has now reached a depth of 240 ft., where four veins have been opened up. Within the last week another new vein, known as No. 5, has been cut on this property at the lowest level. On Lot 38, across the lake from the Big Pete, a new vein has been uncovered on the surface which closely resembles the rich No. 2 vein on the latter property. The Kerr Lake Crown Reserve's new vein is considered as rich as the Bonanza 49 on the Nipissing, or possibly richer, but not so wide. The vein is 25 in. wide, with large slabs of native silver standing up perpendicularly.

Cobalt, March 12.

MEXICO.

SONORA.

The Mejia Mining Co., which is operating a great antigua at Las Planchas de Plata, from which mine the company takes its name, has ordered a Merrill mill from San Francisco, whence the machinery is coming by steamer to Guaymas. As soon as the machinery reaches its destination it will be assembled and put in operation.

The Tribine Mining Co. has let a contract to the Arizona & Sonora Mfg. Co. for the erection of a reduction plant on its property in the Magdalena district beyond the Santo Domingo river. It will include a 20-stamp mill, power plant, and cyanide plant. Work will be commenced immediately, and the plant is to be completed and in operation by the first of September. At the mine development continues most satisfactorily, and it is reported that there is in sight sufficient ore to run the mill two years or more. A mill-run of 30 tons made recently in the Tucabe mill produced results that are reported as quite satisfactory.

COAHUILA.

The final payment of $220,000 has been made for the Boca del Cobre mine, 40 miles from Pedricena. In October, 1906, the property was bonded, and since December, when active development was commenced, the ore shipped to the Torreon smelter has produced $171,000 net. The company has now decided to develop the mine more actively, and a large shipment of machinery has been made from Denver. This consignment includes a 12-drill compressor and drills, two winze hoisting engines, an electric plant and a large quantity of tools.——The Purissima mine, near Bermejillo, has been bonded by local operators, and active development will be started.

Special Correspondence.

MEXICO.

Cyanidation at Pachuca.—Old Mills Change.—New Plants.—A Drainage Adit.—News From El Oro.

Following close upon the success which has been met by all in the old camp of Guanajuato in the use of the cyanide process for the treatment of its ores, comes now the almost full adoption of the same at the quite as famous old camp of Pachuca, which for over four hundred years has been a remarkable producer of the precious white metal. And even the name itself, Pachuca, which is said to mean, in Aztec, the 'City of Sighs,' is, according to traditions handed down from that race, derived from the result of a great battle fought by them to maintain the possession of their mines above the settlement; Pachuca being, as it were, on the road to Real del Monte, 1000 ft. above. The Spaniards finally obtained control, however, and here in 1557 the patio process was discovered and introduced by Bartolomé de Medina. Though these Spaniards practically abandoned their workings as soon as water was encountered and took up new ground, still for the treatment of all the ores there was no change from the patio process until the smelters came into Mexico, when the higher grade ores went there for treatment. But the medium and low grades were still treated on the patio until the purchase of the Real del Monte mines by the United States M. S. & R. Co., and their experiments proved conclusively the adaptability of the cyanide process in the treatment of Pachuca ores, and the company immediately began the erection of two 180-ton plants. But to the old Hacienda of San Francisco belongs the title of pioneer in the cyanide process in Pachuca, for, after an idleness of practically six years, it was quietly changed over and began using the cyanide treatment last year. It was soon followed by the Medina and then La Union. Now the United States M. S. & R. Co. has finished its two mills, the Loreto and the Guerrero, and will probably have them both in full operation before the end of April. The San Diego, which has been idle for two years, has resumed operation with concentration and cyanide. The Guadalupe of the Santa Gertrudis will probably soon be turned over to the cyanide treatment. The Amalgamated M. & M. Co., operating El Chico, and the Hidalgo Copper M. & S. Co., operating at Zimapan, both under the control of the Ludlow Bros., will use cyanide on such ores as are suited. And thus in this old camp, the birthplace of the patio, the time-honored Mexican process will soon be a thing of the past. But almost of as much interest and importance to the camp as the introduction of the cyanide process is the work being done by Gabriel Mancera of Mexico City. This is the drainage adit of Pachuca, which was started in a small way some 15 years ago, with the primary object of draining Atotonilco, El Chico, and adjoining mines. Now, however, a ₱100,000 electric plant is being installed, and it is believed that with the modern machinery that is to be introduced, the work may be completed in four years. Pachuca is now spending close to ₱1,000,000 per year in handling its water, but with the completion of the adit the greater part of that amount will be saved, as the adit will strike in about 200 metres deeper than the present lowest workings, will be 10 kilometres in length, and will drain El Chico, Pachuca, Real del Monte, and Azoyatla.

The camp of El Oro, in the State of Mexico, has not been materially affected by the decrease in the price of silver, for the greater value of the ores being in gold the higher rate of exchange has tended to equalize the loss in the silver value by reason of the low price of that metal. The three principal mines, El Oro, Esperanza, and Dos Estrellas, continue with about their same productions and high returns of something over $100,000 per month each. On the other side of the hill from the Dos Estrellas, in Tlalpujahua, the La Lucha mine has made a nice strike, and its 50-ton mill, which is in course of construction, will probably be placed in commission during April. Neither the Sirio nor Los Pleyades shafts of the El Oro Mining & Railway Co. has found the San Rafael vein, so that some uncertainty is felt in that quarter, but it is believed that it is a faulting and that the vein will be found by the shaft of the Descubridora company. For the last 250 ft. in this shaft good stringers assaying well have been encountered, and at the 750-ft. level two cross-cuts are being run, and the same are closely watched, as they should test the value and extent of the Chihuahua, Calera, and Descubridora veins, and the southerly course of the San Rafael vein, which latter, if proved, will open up a large new territory of great value to the El Oro district.

The Patio Process.

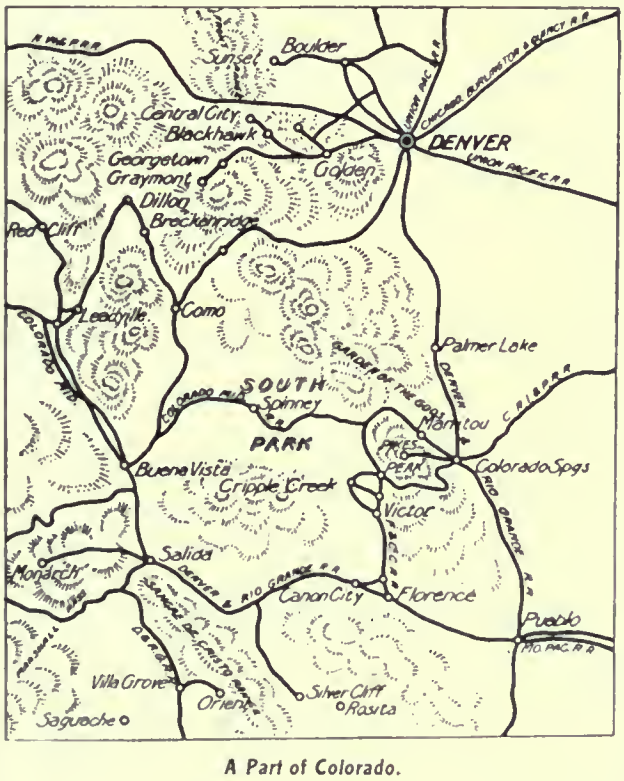
BUTTE, MONTANA.

Resumption of Mining.—Cost of Copper.—Surplus of Labor.—Butte Consolidated.—Butte & London.—Ore Market.

The return to normal mining at the Amalgamated properties is slower than had been expected, though Mr. Gillie said when orders for resumption were given that the normal output of ore from the mines would not be reached before the first of April. It is yet too early to determine if the orders for better results from the miners and the observance of greater economies in operations have borne fruit, but it is believed that when the returns are made from the various departments that they will show a material reduction in the cost of Amalgamated copper. It had been generally believed that the average cost of Amalgamated production was, during recent years, in excess of 11 c. per lb., but it is stated on good authority that the cost was not more than 10½ c. per lb., including refining and selling. It is the expectation that this will be reduced. The cost of production during recent years increased rapidly, in spite of the fact that the value of the ore mined increased also. The increasing cost was due, however, to causes that affected other districts as much as

they did Butte, such as the higher price of lumber and other supplies, the increase in wages, shorter hours, and inefficiency of labor.——The resumption of mining is raising a serious difficulty, as thousands of idle men from all parts of the West, including hundreds of Nevada miners who were locked out by the trouble at Goldfield, have been flocking to Butte, and there are thousands of applicants for work for whom there are no places.

The new section of the Butte district several miles north of the North Butte mines, which the Butte & Bacorn Co. started to develop, is being demonstrated to be of great promise by the Butte Consolidated Copper Co. This company, of which Capt. Alvin P. Nipgen of Butte is president, is financed by Cleveland and other Eastern capitalists. It owns 10 patented claims adjoining the properties of the Butte & Bacorn on the north, and also has 24 unpatented claims. When the Butte & Bacorn Co. stopped work, the Butte Consolidated began to develop its ground



A Part of Colorado.

by sinking a two-compartment shaft on the Susie claim. The shaft has reached a depth of 150 ft. and opened such a large volume of water that the miners were flooded out. The shaft is sunk on the vein and sulphide ore was reached at the water-level. The sulphide and the water are significant and encouraging indications. Assays of gold and silver, and a trace in copper have been taken. No water in any quantity has been encountered by any of the other developing operations in the neighborhood, and even the Butte & Bacorn Co., at a depth of 1000 ft., has very little water. The surface and vein characteristics are identical with those of the famous Anaconda hill. The Butte Consolidated Co. has a fine tunnel-site and may conclude to open the property by that means, but that has not been decided on. An adit would give a depth on the Susie vein of about 500 ft.——There are no immediate prospects of a resumption of work by the Butte & Bacorn Co., as financial conditions among its Pittsburg friends have not yet become satisfactory. The company has a lot of money coming on subscriptions, but since the panic it has been impossible to collect it.

The Butte & London Co. is continuing its exploration work on the 1100-ft. level, and the results are becoming most satisfactory. The east drift from the south cross-cut is showing up well. Assays yield an average of 5.7 oz. silver, $2 in gold, and 2.3% copper. The character of the vein encourages the belief that a large body of commercial ore will be opened soon in that vein.——The Davis-Daly Estates Copper Co. has cut another vein in the Colorado. It was found by the east drift from the 1000-ft. level, but its extent is yet unknown, as driving is being done on a 2-ft. vein of ore, which is being opened. The ore assays 40% zinc, and contains little else in mineral value, but it is worth $15 per ton to the company. This vein, like the one opened south of the shaft, has a northwest strike. Work is also progressing in the cross-cut on the 800, which will develop the vein that was opened on the 1000-ft. level south of the shaft.

With the re-opening of the Washoe smelter at Anaconda and the announcement that it will again receive custom ore, a number of lessees are starting work in this district. As the North Butte is transferring all its ore to the Washoe plant, the Butte Reduction Works is open to a larger number of custom ore shippers. The East Helena smelter has also reduced its rates somewhat, and a number of markets are therefore being offered to lessees.

DENVER, COLORADO.

Activity at Leadville.—The Vidler Tunnel.—News From Idaho Springs.—Upper Clear Creek.—Mining at Silverton.—United Rico Mines Co.—Output of Cripple Creek.

Leadville is slowly coming back to normal conditions as the general metal market improves. Output for February was approximately 60,000 tons, which is a 10% increase over the preceding month. The re-opening of the Tuscan mine contributed largely to improve conditions, and this mine will add considerably to its working force during March. Many of the smaller properties in the district have resumed work, and are maintaining a small daily output. William P. Malburn of Denver has purchased a sixteenth interest in the Greenback property at Adelaide Park, near Leadville. The control of this mine is now in the hands of W. A. Clark and others of Salt Lake City.

Georgetown is getting a great deal of undeserved notoriety, especially in England, by the exposure of the Vidler tunnel scandal. It is another case of a promoter getting into the confidence of foreign and American capitalists and convincing them that it was unnecessary to have a reliable engineer's report on the property before they invested. It is to be hoped that this simple rule will be learned some day by all who have money to invest in mining ventures. ——Operators at Idaho Springs have been wanting a local smelter for some time. The recent development work on the Saratoga lateral from the Newhouse tunnel has been so encouraging that the manager of that property has leased the smelting plant at Golden, which belongs to Berry brothers of Detroit. Repair work is now in progress. It is estimated that the mine will be able to supply the smelter, should the present rates be cut by competition to such an extent that custom smelting would become impracticable.——The Headlight and Halifax claims near Empire have been let, with option to purchase if the examination is satisfactory. The workings are being unwatered preparatory to inspection. The properties are equipped with hoisting and pumping machinery and all necessary buildings.

There is more than the usual amount of development work in the Upper Clear Creek district. All the mines connecting with the Newhouse tunnel are working larger forces than for several months. Lessees in the Gem mine are finding especially good ore. The only difficulty now apparent in the dis-

trict is the inability on the part of many to get their ore to market as fast as produced. The Summit vein in Silver Age gulch has been cut again at over 500 ft. on the dip. This was a good producer in the upper levels and has been eagerly sought several times since it was lost, pinching out, apparently.

Mining activity in Silverton is seriously affected by the recent snow-slides. The soft weather of early March caused several slides to run, doing considerable damage, and injuring a few people. The Iowa mine had part of its buildings demolished and some of its employees injured. One slide carried away part of the Silver Lake tram, and badly wrecked the tram-house. Mine buildings have been destroyed by the slides on Mineral creek. Telephone lines throughout the district are down, as are also the power lines of the Animas Power Co. The damage thus far reported will amount to at least $16,000. ——The property of the Custer Mining & Realty Co. has been sold by the sheriff to satisfy a claim of only $745.——The Bull Domingo mine, which was closed recently on account of a cave, is being reopened.—— The United Rico Mines Co., at Rico, has changed the Pro Patria mill to treat lead-zinc ore by magnetic concentration. The company has also given leases on some of its property on Newman hill. Increased activity is evident at Telluride and Ouray. The ore-carrying companies are increasing the number of their teams and burros as much as 50% in some cases.

The control of the El Paso company is settled for another year, and now the reports from Cripple Creek should become less belligerent than of late. The old board of directors was re-elected. The Drainage Adit is progressing rapidly, having advanced 350 ft. in the last thirty days. This excellent progress is encouraging to operators whose ore reserves above the water-level are limited. A drilling contest, which is to last 14 days, has been arranged by the different makers of the small hammer-drills used in the camp. The contest is to be held in the Last Dollar mine, which is under lease to the Western Investment Co. The arrangement is for 4-ft. holes in sinking, raising, and driving. The competing machines are the Shaw, Waugh, Murphy, McFarland, Sullivan, Traylor, Hardsocg, and Jones. The first conviction under the new law which makes 'high-grading' equivalent to grand larceny, was made in the District Court at Cripple Creek on March 7.——The output from Cripple Creek for February was 58,222 tons, exceeding the tonnage for January by 1,437 tons. The value of the output was $1,241,613, which is $94,207 less than the preceding month. The decrease in the grade of ore was due to the recent favorable rates on low-grade ore. It is now possible to ship at a profit ore worth less than $8 per ton.

The demand for leases was never so great as at present. There is scarcely a mining company that has any promising ground that has not received several applications. Dump leases are especially sought. The manager of the Stratton estate reports over 100 applications for such leases. A large number of properties that have been idle for several years are starting up, and in several instances good strikes have already been made. The ore-hauling concerns are unable to transport all the ore offered to them. They are increasing their equipment as fast as possible. The railroads are likewise being pushed to their fullest capacity to get the ore to the plants at Florence and Colorado City. The deep drainage adit continues to advance at the rate of a little over 10 ft. per day, which is just twice the rate under the former contractors. The contract for the intermediate shaft has been let, and work is already in progress at that point.——The Portland Gold Mining Co. is being sued by the State of Iowa for taxes claimed to be due. The Portland company was incorporated under the laws of Iowa, and that State now regards it as an outside corporation and subject to the tax which the State law levies on such corporations. The outcome of the case is of considerable interest, as well as the feeling which it indicates as growing in the minds of legislators that if a corporation receives something from a State, the State should likewise receive something from the corporation.

TORONTO, CANADA.

The Canadian Mining Institute.—Important Meeting.—Valuable Papers.—Exciting Election.

The annual meeting of the Canadian Mining Institute was held at Ottawa, commencing March 4, and was largely attended. F. Keffer, the president, in his annual address referred to the expected visit of the London Institution of Mining & Metallurgy next autumn, on the invitation of the Canadian Institute. He expressed gratification at the growth of the Institute, the membership of which had increased from 500 to upward of 700 during the year. He deprecated the dissension that seemed to be developing between the Ontario and Quebec members, and favored the preservation of the national character and scope of the organization, in preference to the formation of provincial bodies.

A very full program of papers and addresses was presented. R. Hedley described how 3000 tons of ore per day was handled at the Granby mines and smelter. H. P. H. Brumell read a comprehensive paper on the 'Modes of Occurrence of Canadian Graphite.' J. Obalski spoke concerning 'Gold in the Eastern Townships of Quebec,' where a quarter of a century ago mines had been worked along the Gilbert river, in the Chaudiere valley, yielding gold to the value of $2,000,000. D. B. Dowling, of the Canadian Geological Survey, described mining conditions in the Rocky Mountains, showing a number of fine photographs taken by him in the course of his explorations for coal. John McLeish, of the Canadian Department of Mines, presented the preliminary report on the mineral production of Canada in 1907. The total production was $86,183,477, as compared with $79,057,308 in 1906. Of last year's production, $42,434,087 was metallic and $43,449,390 non-metallic. The items of metallic production were as follows: Antimony ore, 2016 tons, $65,000; copper, 57,381,746 lb., $11,478,644; gold, Yukon, $3,150,000; elsewhere, $5,114,765; total, $8,264,765; iron ore (exports), 25,901 tons, $45,907; pig iron from Canadian ore, 107,599 tons, $1,982,307; lead, 47,565,000 lb., $2,532,836; nickel, 21,189,793 lb., $9,535,407; silver, 12,750,044 oz., $8,329,221; cobalt, zinc, etc., $200,000. Of the non-metallic items the most important were asbestos, 62,018 tons, $2,482,984; coal, 10,510,961 tons, $24,560,238; petroleum, 788,872 bbl., $1,057,088; and portland cement, 2,368,593 bbl., $3,374,828.

A number of papers dealt with iron ore and iron and steel manufacture. One of the most important was by C. K. Leith, who, in a paper on 'The Iron Ores of Ontario,' pointed out the opportunities presented by Canada for metallurgical industry. A. B. Willmott, of Sault Ste. Marie, in treating of the iron and steel industries of Ontario, presented some interesting facts as to the development of these enterprises. R. H. Sweetzer, of Columbus, Ohio, dealing with the use of charcoal as blast-furnace fuel in northern Ontario, contended that the abundance of material for this fuel should make the province independent of all outside fuel sources. F. N. Flynn, Arthur A. Cole, and Frank C. Lowry read papers dealing with the Cobalt silver deposits.

Resolutions were adopted favoring the continuation and increase of the bounty on lead, and a deputation was appointed to wait on the Government regarding the matter. Dr. Goodwin moved a resolu-

tion recommending to the Minister of Mines that a conference be held with the heads of the provincial bureaus of mines to devise, if possible, a uniform method of collecting statistics and valuing mineral products. The resolution was adopted. The election of officers resulted in a keen contest over the positions of secretary and treasurer, many of the Ontario delegates favoring the election of H. E. Haultain for secretary, and Milton L. Hersey as treasurer, with a view to having the headquarters of the Institute removed from Montreal to Toronto. The number of votes cast was 342, the largest in any election so far held, and the result was in favor of the old officials. The following were elected: President, Willet G. Miller, by acclamation; 1st vice president, G. E. Drummond; 2nd vice president, W. F. Robertson; secretary, H. Mortimer Lamb; treasurer, J. Stevenson Brown; council, W. M. Brewer, Arthur Cole, R. H. Drury, Chas. Fergie, J. E. Hardman, R. T. Hopper, J. McNabb, W. F. C. Parsons, R. W. Robb, O. B. Smith, R. H. Stewart, and J. B. Tyrell. The question of a change in the headquarters will be decided by a mail vote.

A good deal of attention is being attracted to the new camp lying south of the township of Lorraine in unsurveyed territory, where a discovery was first made in the fall, since when over 200 claims have been taken up. It lies three miles west of Lake Temiskaming, and about 22 miles south of Cobalt. The Haileybury Silver Mining Co. started to work on a location here some weeks ago on a vein of cobalt-niccolite, carrying silver, and is sacking ore from an open-cut. The Keeley property is also yielding ore. An early rush to the camp is expected. It is about 10 miles distant from Temagami station on the Temiskaming & New Ontario railway. Shipments in the summer can be made by way of Lake Temiskaming.

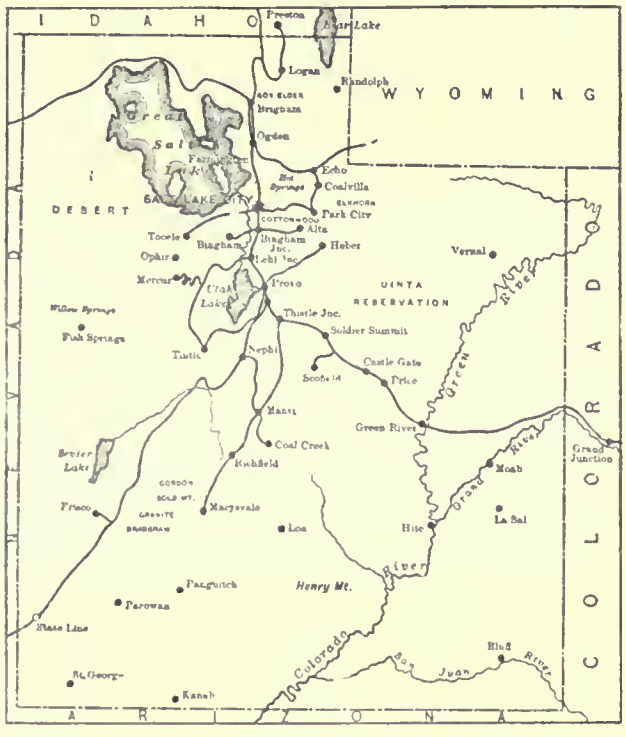
SALT LAKE, UTAH.

Sale and Consolidation of Mines.—Shipments From Park City.—Output of Tintic.

The revival of mining at Butte and other parts of the West is being felt in the coal camps of southern Utah. The demand for fuel has increased. Sunnyside coke is in demand at the Butte and Anaconda smelters.——A deal has been closed for the sale of the Century mine in the Park Valley district (in Boxelder county) to a New York syndicate. The first payment has been made, and the second will be forthcoming in 90 days. The Century mine has been a dividend-payer in the past, and is equipped with a good milling plant. The purchasers propose to install an electric-power plant and operate the property upon an elaborate scale.——The merger of the Ohio Copper and Bingham Consolidated properties is being arranged satisfactorily. The Bingham Con. properties, which are in debt nearly $1,500,000, are to be turned into the Ohio Copper Co. free of incumbrance, and it is understood that in consideration of 3⅓ shares of Ohio stock being issued for one share of Bingham Con. stock, the shareholders of the latter are to turn into the Ohio treasury $1,000,000 in cash. The proposition will shortly be submitted to the shareholders of both corporations.——The Utah Copper Co. has had trouble lately with the power-plant at its Garfield mill, and therefore the production during March will fall short. For the same reason, the ninth section of the mill has not been placed in commission, but it is ready to start.

Ore shipments from the Park City mines last week amounted to 835 tons, the contributing mines being: Daly Judge, 254; Daly West, 149, and Silver King, 432 tons. The water in the Ontario drainage adit is receding at the rate of more than four feet per day, and at last accounts was 80 ft. below the 1200-ft. level of No. 3 Ontario shaft. It is expected that the drainage will be complete to the adit-level before the end of May, when it will be possible to clear out the last section of the obstructed portion of the adit. It is generally considered that the Ontario drainage adit is the key to profitable mining at Park City, and its restoration is eagerly awaited. In the American Flag and other mines, levels that have been flooded since the caves occurred, over three years ago, are now accessible.——The new zinc plant of the Grassalli Chemical Co., at Park City, will be in commission about April 1. It will begin operation on zinc middling from the Daly Judge mill.

The case of the Black Rock Mining Co. against the State of Utah has been won by the defendant. The suit was brought to test the constitutionality of the incorporation tax law passed at the last session of the legislature. An appeal will be taken to the Supreme Court of the State. The plaintiff set forth in the complaint that the enforcement of the law would amount to double taxation and therefore could



Utah.

not be constitutional.——The Black Jack Mining Co., at Tintic, has begun driving a 2000-ft. tunnel, which, when completed, will reduce the cost of ore extraction as well as expense of transportation to the smelter. The Eureka Hill railway will transport the ore to the Tintic Smelting Co.'s plant for 25 cents per ton.——A special meeting of directors of the Columbus Consolidated Co. is scheduled to be held during the week, and it is probable that an assessment of 20 cents a share will be levied. The Columbus is at Alta and last year paid out $226,000 in dividends; but production ceased when metal prices fell last autumn. In the meantime, development work has progressed, with the result that the company has overdrafts at the bank.——The directors of the Nevada Hills Co. have decided to pass the March dividend, and it may be several months before another one will be posted, since mill construction and other improvements are planned. The Nevada Hill mine is at Fairview, Nevada, but the headquarters of the company are here.——Ore shipments from Tintic last week amounted to 53 car-loads, the contributing mines and amounts being: Centennial Eureka, 45; Bullion Beck, 5; Eureka Hill, 2; Tintic Iron, 1 car-load. All but about 50 tons per day of the Centennial Eureka product goes to the Mammoth smelter at Kennett, California, for treatment.

RAWHIDE, NEVADA.

The Boom.—Character of the Ore.—Specimens and Assays.—Mill Construction.—Distribution of Claims.—Leasing Companies.—Reported High-Grade Ore.

The town of Rawhide is built along an arroyo that drains southerly to a desert flat surrounded by mountains. On the east side of the arroyo are Grutt, Balloon, and Murray hills, connected, one to the other, by saddles; while on the opposite side is Rosebury or Hooligan hill. These hills are centres of activity in prospecting and development. Another centre of activity is in the foothills of the higher range two miles west of town, where there are two or more parallel veins having the same north-south strike as those that cut through Grutt and Balloon hills. The holdings of the Rawhide Queen Mines Co. cover the major part of Balloon hill, containing what is believed to be three different veins. On the westerly slope of the hill is the principal vein, having a rhyolite dike as the hanging wall, giving the vein an easterly dip. Another vein, having the same general strike, is found on the easterly slope, but having a westerly dip. At the top of the hill is a fairly defined vertical vein. Kearns leases No. 1 and 2 cover a portion of the vein on the westerly slope. The principals in this company are E. W. King, W. Law, Daniel Snowgosse, J. H. Barrett, and G. W. Lloyd. The company has leased out most of this ground to 15 sets of lessees, the term of leases being 18 months. The Kearns leases have two shafts over 100 ft. deep, with some cross-cuts and drifts, showing 8 ft. of ore on lease No. 2. The ore sacked and shipped is said to have run from $117 to $200 per ton. A gasoline hoist has been installed on this property. The Rawhide Lode Leasing Co., having a lease on a portion of Balloon hill's principal lode, has a 130-ft. shaft, with a cross-cut at the 100-ft. level to the ore, showing a vein 10 ft. wide said to assay $100 per ton. L. R. Thatcher, manager of this lease, has ordered a gasoline hoist.——Grutt brothers practically control Grutt hill, which has one well defined vein cutting through it. Much of this ground is leased. The Grutt Mining Co., operating a lease on the Wild West claim, has 6 ft. of ore said to be worth $200 per ton. The same company is developing the Grutt fraction. The Last Chance lessees, on the north end of the hill, have five shafts from 10 to 50 ft., with some open-cuts, showing ore. Grutt Bros. likewise have 190 acres on Murray hill, the Grey Eagle Fraction between Balloon and Grutt hills, and some ground between Murray and Rosebury hills. The Murray lease on Murray hill is one in which some excellent ore has been uncovered.——The Owl group, on the south slope of Rosebury hill, contains 95 acres, and is in the hands of 27 lessees, 20 of whom are at work. On this hill there appears to be a number of veins, which carry silver in sulphide and chloride form, as well as gold. The greatest depth here is 50 to 60 ft. The Big Four Leasing Co., operating on Murray hill, has some of the highest-grade ore thus far found in the district. The vein is 4 ft. wide.

The Miller lease, on Rosebury hill, was taken over by Thos. Kearns and associates. It has an 80-ft. shaft and 100 ft. of drift on the vein at the 50-ft. level. It is asserted that it contains three feet of ore that samples $300 per ton.——The Rawhide Coalition Mines Co., owning the unsold lots in the townsite and adjacent mineral ground, is now in control of E. W. King and asociates. The Rawhide Junction M. Co., having ground on the lower part of the gulch, has let 12 leases, and some of the lessees are at work. By sinking to bedrock, at 54 ft., the wash was found to be of value as placer ground. It is stated that both wet and dry placer machines are to be used to handle the stuff. Charles A. Gehrmann of the Bank of Rawhide is concerned in this enterprise.——In the western part of the district are the Royal, Tiger, Bushwhacker, Jack Pot, Nevada King, Regent, and others. Here the veins are well defined and strong, and at 50 to 115 ft. depth a good grade of ore has been obtained. The Royal is under lease to John E. Pelton and associates, and a considerable tonnage of ore is being sacked. There are more sulphides in this ore than appears in that of Balloon and Grutt hills. The Tiger is so located as to enable the lessees to develop through adit levels. One of these opened an 8-ft. vein of ore, some of which runs $200 per ton. The lessees are R. E. Lee and C. G. Elliott. The Bushwhacker was sold to Capt. G. W. Thatcher for $20,000. It adjoins the Royal and Tiger, and has two veins carrying high-grade ore.

There are approximately 300 leases in force in the district, and many of the lessees are companies, whose stocks are on the market. Many of the leases are offered for sale at high prices; the fairly long terms of the leases, one to three years, make them attractive to traders and speculators. While much work is in progress on some of the leases, there are others apparently being held for sale, and the work being done is merely to meet the agreements.——C. E. Loss of the California Contracting Co., E. W. King, Fred Grutt, and S. D. Crump are the organizers of a company that purposes building a railroad from Schurz to Rawhide, a distance of 31 miles. It is announced that the road will be built within the next six months. J. A. Carmichael has spent some time in Rawhide making tests with a view to erecting a custom mill. He believes Rawhide will eventually become a great milling district.

When the psychological moment arrived, Rawhide blossomed forth in all her glory as a full-fledged town with over 6000 fortune-hunters. The strike at Goldfield, the closing of mines in other localities, and the fact that there had to be a mining excitement in Nevada, made Rawhide possible. Aside from this, it is a fact that Rawhide has some extraordinarily rich surface showings, some of which are merely knife-blade streaks; but the gold is there and the lessees and mine-operators have faith that these 'knife-blades' will open out into bonanzas or enrich the dikes sufficiently to make shipping ore. Some of these expectations have been partly realized. The dikes of quartz porphyry and andesite breccia, when sufficiently silicified, yield profitable ore, but the dikes are only mineralized in part; if they were mineralized throughout one could figure on a certain tonnage of a given class of ore, but such is not the case, so that good ore in one portion of a dike is no guarantee of the same condition in other portions. As to the mineralization continuing downward, there is a marked improvement to the shallow depth already reached, but whether this will extend below the zone of secondary enrichment remains to be proved.

There is no doubt that with favorable conditions, such as cheap and efficient labor, cheap power and timbers, there would be ore for many large mills; but such is not the case; with high union labor, almost prohibitive timber costs, and no cheap power, only the best grades of milling ore can be worked. Some of the lessees are shipping ore ($50 to $250), but the great majority are only expending money.

The camp is an ideal one for boom purposes; high assays are common, the ore yields fine specimens, and the area over which good ore has been found bids fair to make a number of profitable mines. As compared with Goldfield at the same age, the comparison is in favor of Rawhide; but the deposits being of a character not well understood, the future is difficult to predict. The sociological experience of Goldfield is likely to be repeated here, and a new boom in some

other locality in Nevada is apt to divert interest to a fresh scene of excitement.

A branch railroad from Schurz to Rawhide will be built, and as there are no engineering difficulties to be overcome, the construction will depend upon the delivery of construction material at Schurz. There is talk of half a dozen mills being put up here, but this will depend upon how readily the public subscribes to the undertakings. That there will be a big mill here or at Walker lake, there is little doubt, but there being no regular tonnage available or possible to be guaranteed at present, it is too soon to figure on big mills. We are in the assay stage, with the usual exaggerations. The $76,000 assay from the Hooligan claim came from a stringer, it represents a sack-full of ore and it may take three months more work to get another sack-full of the same kind of stuff. When a stringer like this is blasted, an assay of the fine stuff from the bottom of the shaft may yield $400 for "the full width of the shaft." That sort of thing is common in all boom camps. It misleads the inexperienced.

The I. X. L. Mining & Leasing Co. has a 15-hp. gasoline hoist ready to put up. The shaft is down 75 ft., and driving and cross-cutting will be started on the 100-ft. level. On the Big Four lease within 6 ft. of the surface some very rich ore was uncovered. The stringer is from ½ to 6 in. wide and shows big crystals of gold. Kearn's No. 2 lease does not exhibit such a specimen ore, but it pans better over a wider area. The Burns lease on Silver King hill shows a 16-in. streak of blue quartz mineralized with sulphides.

LONDON.

Cornish Tin Mining.—Broken Hill Proprietary.

The results at Dolcoath during the second half of 1907 show what effect the fall in the price of tin has had in reducing profits. The total amount received from the sales of concentrates was £80,549, as compared with £104,094 during the first half of the year. The ore crushed was 49,795 long tons, yielding 845 tons of concentrates. The product per ton of ore was 38 lb., and the average price of the concentrates was £95 6s. per ton. During the first half of the year 51,243 tons of ore yielded 863 tons of concentrates, the product was 37½ lb., and the price £120 11s. 9d. For the last five years the output and yield per ton have kept at about these figures, and the price of tin has been the sole cause of variation in the receipts. Twelve years ago, when the present company was started, the amount of ore crushed was about three-fifths of what it is now, and the product of concentrates per ton was almost exactly double, so that the actual output of concentrates was over a thousand tons in the half-year. On the other hand, the price of tin was wretchedly low, the average return from the concentrates being only £30. To return to the past half-year, the total income from all sources was £82,415, the working costs were £60,283, and the lord's royalties £5376, leaving a net profit of £16,755. This compares with a profit of £41,421 during the first half-year. The directors propose to pay a dividend of £12,750, which is at the rate of 7½% on the paid up capital of £340,000. During the previous half-year the dividend was at the rate of 20%. The company is well provided with working capital and has ample reserve cash. These resources consist of £47,798 in cash and £28,390 in consols, and were accumulated during the recent boom in tin. Perhaps the most interesting item in the report is the income of £130 from the sale of copper and arsenic. Though small, it shows that the Elmore vacuum plant mentioned by me in a recent issue is beginning to yield returns. The amount mentioned is not very much, it is true, but I look for substantial returns during the current year.

The fall in the price of tin has hit the Carn Brea & Tincroft company in such a manner as to bring the balance on the wrong side for the half-year ended in December. The receipts were £41,363 and the working costs £42,726. In addition, there were lord's royalties amounting to £1568, so that the loss on the half-year was £2931. The ore is lower grade than at Dolcoath, and it contains wolfram, arsenic, and copper as well. The ore treated was 29,677 tons, and the tin concentrates sold was 396 tons, a recovery of 29.9 lb. per ton. The receipts from tin concentrates were £34,649, an average yield of £87 per ton. I would here interpolate the remark that I use the plural advisedly when speaking of concentrates, as every Cornish mine produces a series of grades. The receipts at Carn Brea & Tincroft included £140 for copper ore, £2323 for arsenic, £689 for wolfram, and £3871 for tin in residues. These two mines have belonged to the present company since 1900, and production has been pretty regular. As a rule the balance has been on the wrong side and, owing to the method of bookkeeping, it is somewhat difficult to ascertain whether the costs are charged to capital or revenue. During 1905 and 1906 and the first half of 1907 the accounts showed profits. My own opinion is that the company should raise new capital and re-organize its methods of working and dressing. The accompanying photograph is a view of Dolcoath and Carn Brea that I took when in Cornwall last October.

A Group of Cornish Mines.

The Broken Hill Proprietary Co. has published the results of working during the six months ended November 30. The ore treated was 298,327 tons and the output was 2,785,535 oz. silver and 29,612 tons of pig lead. The average prices obtained were 2s. 9d. per oz. silver and £16 4s. 9d. per ton lead. The zinc concentration plant treated 175,021 tons of zinc tailing, producing 41,203 tons of zinc concentrate. The profit for the half-year was £137,642, being 8s. 9d. per ton of ore treated, as compared with £1 0s. 9d. during the previous half-year. This drop is accounted for chiefly by the fall in the price of metals, but it is also due to the extra expenditure on development, £40,000 having been spent in this way, equal to 2s. 6d. per ton of ore treated. The company had in hand large balances of undistributed profit from the two previous half-years, so it has been able to pay £288,000 in dividends during the half-year in question.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The speed of a belt is found by multiplying the diameter of the pulley in feet by 3.14 and by its revolutions per minute.

One pound of natural gas occupies 22 cu. ft. at 62°F. One cubic foot requires 10 cu. ft. of air for its combustion, and evolves about 1000 B. T. U.

The Sutro tunnel enters the Comstock lode at a depth of 1700 ft. The length of the main tunnel is 3⅞ miles, and the cost of construction, $2,096,566.

Antimony in gold ore forms a voluminous amalgam, and gives considerable trouble in the clean-up, though it does not in any way hinder amalgamation of the gold.

Selenium occurs in the ores of Tonopah, and the presence of it is indicated by the cherry color of the condensed fume obtained when parting the bullion in the last slag of smelting.

Secondary enrichment at Butte is exceptional in regard to the depth at which secondary sulphides occur. The ground-water level has risen as a result of faulting on the western face of the granite hills to the east of Butte.

A one-inch four-ply belt, traveling 900 ft. per min. will transmit 1 hp. The power increases in direct proportion with the speed and width of the belt. For instance, a 2-in. 4-ply belt traveling 1800 ft. per min. will transmit 4 horse-power.

In the chlorination of gold ores, the water should be filtered free from organic matter and should contain neither alkaline salts nor ferrous sulphate in solution. Thus mine-waters, sea-water, and water from many springs and lakes is unfit for use without purification.

In the construction of dams and embankments, the effect of shrinkage should be carefully considered. This may amount to 15% or more. If a rubble dam is to be faced with concrete, care should be taken to allow the fill to settle as completely as possible, so that shrinkage cannot cause cracks in the facing.

Fire-killed timber checks badly when left in the tree, and this is an obstacle in the way of utilizing it for some purposes. For the manufacture of lumber it should be used, if possible, within a year after it is killed, but satisfactory railroad ties have been made from timber killed fifty years previously.

The sulphuric anhydride discharged from the Washoe smelter at Anaconda would produce 2500 tons of sulphuric acid per day. If it is condensed, it will be difficult to find a use for this quantity, but a reduction in cost will develop new processes, and it will stimulate research in the wet methods of ore reduction.

Sulphuric acid is a by-product from the smelting of pyritic ores, and is manufactured locally by the Mountain Copper Co., the Peyton Chemical Works, and the Standard Oil Co. The last mentioned uses the acid in refining its own oil, while the Mountain Copper Co. manufactures super-phosphate, which is used as a fertilizer.

Wet milling is now so general that dry milling is regarded as unusual practice. As a matter of fact, dry milling is by far the older method, and it only gave way to wet milling gradually when it was found that water assisted in clearing the mortar of pulp and assisted in the separation of the valuable minerals from the waste.

Cross-cutting is not sufficiently practised in most mining districts. Parallelism in veins and ore-shoots is common, and systematic cross-cutting usually develops ore. When a cross-cut is stopped, a drill-hole should be driven into the face for 5 or 6 ft. and the drillings assayed. Such a hole is almost as effective as driving the drift forward 5 ft., and is much cheaper.

Legal money is a term technically applied to the gold and silver coined by the Government, the certificates of deposit issued against the same, and the United States notes, all of these being by the statute legal tender. The expansion and contraction of these forms of currency have been regulated partly by statute and partly by the automatic influence of gold production.

Economy in timber has been effected in many collieries by making the ends of the timbers somewhat pointed, so that when the pressure of the ground presses on the end of the timbers, the weakest part is the end, and the timber will fray at the end instead of breaking in the middle. When the timbers are removed, they can be used again, and the loss of length does not exceed a few inches.

Amalgam often contains base metals, such as iron and antimony. After retorting, the resulting sponge may assay as high as 50% of iron. Iron readily amalgamates in presence of sodium amalgam, and in cleaning up batteries where sodium amalgam is used the iron is frequently noticed to be slightly amalgamated in spots. The remedy after retorting to recover as much mercury as possible, is to subject the residue to a thorough oxidizing roast, and then wash out the ferric oxide by means of sulphuric acid, before proceeding to melt the bullion.

Lead is said to act like steel at ordinary temperatures when reduced to a very low temperature in liquid air. It will serve as a helical spring, for example. These facts, which keep cropping up, of the behavior of soft, non-elastic metals are interesting. They show how important temperature is. Just as iron is soft and inelastic at a high red color, so lead is dull and soft at ordinary temperatures, for it is well on its way to be melted. Mercury is actually fluid at ordinary temperatures, but can be frozen at about 20°F into a soft metal. At lower temperatures it may, perhaps, be possible to make springs of mercury.

Puddle is a mixture of gravel and clay which is wet and rammed into place. A good mixture is 1 cu. yd. of gravel, 0.35 of sand, and 0.25 of clay. This will make 1.16 cu. yd. of puddle, and will shrink to 1.1 cu. yd. when rammed. If the bottom of a reservoir is to be covered, the gravel is spread in a layer about 3 in. thick, the clay spread over the gravel, and the sand over the clay, in their respective proportions. An ordinary harrow is then dragged over it until mixing is complete. Water is next sprinkled over it in amount sufficient to cause the mass to knead like stiff dough under a two-ton sectional roller. Such a puddle is as heavy as concrete, and resists abrasion almost as well. The cost of puddle is about 50 c. per cubic yard.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Theory of Ore-Deposition.

The Editor:

Sir—In Hutton's 'Theory of the Earth,' Vol. I, page 394, may be found the following statement: "That mineral veins have been filled with matter in a fluid state, is acknowledged by everybody who has either looked at a mineral vein in the earth, or in a cabinet specimen; mineralists and geologists, in general, suppose this to have been done by means of solutions and concretions, a supposition by no means warranted by appearances, which, on the contrary, in general demonstrate that the materials of those veins had been introduced in the fluid state of fusion." On page 405 of the same volume it is stated by the same Scotch scientist that "there is not a mineral vein (so far at least as I have seen) in which the appearances may be explained by anything else besides the operation of fire or fusion."

These views, which were published in 1795, may well be looked upon as extreme; and the author can hardly escape the criticism of having generalized upon too few facts.

In 1900 Mr. J. E. Spurr published one of his illuminating and suggestive treatises upon 'Ore Deposits,' discussing in this instance* those of Monte Cristo, Washington, of which he speaks as follows: "The ores in the Monte Cristo district consist of pyrite, pyrrhotite, arsenopyrite, blende, galena, and chalcopyrite. Realgar as an alteration product from arsenopyrite is common. Among the rarer minerals are chalcocite, bornite, molybdenite, and stibnite." The ores carry relatively small amounts of silver and gold.

"In the observed veins of the district it is found that the ores are most abundant near the surface."

"Upon various grounds it has been concluded that the upper sulphide zone, which contains the most and richest ore, was deposited, largely at least, since the development of approximately the present topography, by downward tending waters. Lead, one of the most conspicuous metals of this zone, is not known to be present in the lowest ores, and so is not regarded as having been derived by the concentration of ores like those in the lowest zones; but is, perhaps, as the known facts indicate, an original deposit by descending waters. This theory involves the derivation of the lead ores from the surrounding rock. The lower sulphide zones afford less evidence as to their origin, but what there is tends in the same direction as that for the upper zones, so that the general suggestion is deduced that all the zones were precipitated, in part simultaneously, by downward percolating waters, the different belts of mineral being precipitated in order according to their relative solubility. Similar phenomena in other regions, and the known chemistry of such phenomena, support these deductions derived from independent local evidence."

* U. S. Geol. Sur. 22nd Ann. Rep. Pt. II, pp. 777-865.

In brief, Mr. Spurr presents in this report the theory that all the ores of this district, even the most complex and base, were derived by solution from the adjacent rocks, and deposited in joints and other fractures (while the present topography was forming) by descending waters. This again is an extreme view. I do not recall another instance in recent years of such radicalism on the side of the discensionists.

Once more the wheel turns; and in the MINING AND SCIENTIFIC PRESS of February 22, 1908, Mr. Spurr most ingeniously presents a line of reasoning that leads him to conclude "that most ore deposits and mineral veins, as a class, represent one or the other of the extreme products of magmatic differentiation"; and this theory is said to cover, "with a few doubtful exceptions, all the important deposits of metals" with which he is familiar.

Here we are, back again to the Huttonian extreme: and possibly falling into his predicament as to generalization. The existence of 'extremes' is in itself an indication of 'means'; and from the known relation between their products it may be possible to determine Mr. Spurr's actual deductions and conclusions. We may at least infer that he is sometimes torn between two desires, and could be happy with either "were t'other dear charmer away."

In other words, it is difficult for one who found much truth in his Monte Cristo report to take him seriously in his latest article, and impossible to believe that he intends to make his theory as broad as his language indicates. Can it be that he includes under the heading of magmatic differentiations the disseminated and replaced limestone ores of the Mississippi Valley, when no eruptives younger than the sediments occur within fifty or a hundred miles? Or the world-wide copper strata of the Permian and Triassic periods? Or the copper ores at Bisbee or Butte, where the valuable ore minerals are so clearly secondary? Or the drainage-slope joint-fillings of Monte Cristo? Of course his theory is not intended to cover the goldfields of the Rand, nor the native copper ores of Lake Superior. Nor does it seem to answer the requirements of the enormous copper impregnations in sandstone in the Congo Free State. The list of possible exceptions that quickly come to mind is therefore somewhat formidable; and we are startled out of our usual attitude of ready acceptance of Spurr's conclusions, to a more careful consideration of his new theory.

What restless fellows, these geologists! We no sooner learn from one authority that ore deposits are formed by underground waters than along comes another who proves that these waters are not chiefly ascending but *circulating*. And when we have settled down to an acceptance of the effective agency of circulating and descending solutions we are shown that they cannot and do not descend very far; but may originally all have arisen from magmas at great depth. Then we admit the agency of magmatic waters in the deposition of primary ores; and presto! we are asked to forget all we know about the deposition of ores from solutions far removed from any magmas; to abandon the firm ground of

the formation of the richer portions of veins by secondary enrichment through descension, and to place ourselves upon the shifting and uncertain territory of magmatic differentiation. We are now to look upon most deposits of the metallic ores, as 'dikes' that are 'intrusive' into the country rocks where they are found. Water itself is to be considered as an ultra-refined magma, and quartz, next to ice, its final crystallization product.

No longer shall we find it necessary to warn clients of the possibility or probability of early exhaustion of their secondary bonanza ores, and the approaching days of famine and leanness; for it will be possible to recognize "successive vertical zones of ore deposition," and "there may result in a vertical section of orebodies (or) zones of deposition separated from one another by barren intervening spaces." In other words, a mine may contain as much rich ore at the depth of two miles as within a thousand feet of the surface. New hope for the prospector; new life for hundreds and thousands of mines abandoned because their ores became too low-grade to mine profitably! No longer need we fearsomely anticipate the exhaustion of our mineral resources; for "the metallic hearth or the factory in which the ores originate is the zone of differentiation, which is in the lower part of the zone of crystallization" (or say from 5000 to 10,000 metres below the surface). And everybody knows that our deepest sulphide mines have not as yet attained the depth of 1000 metres.

It has been customary for several years past for writers on ore deposits to call attention to the generally close relation existing between ore deposits and igneous rocks. It seems about time for someone to emphasize the relation between the richer ore deposits and the top of the ground; for here is a relationship of far greater practical importance and quite as close consanguinity.

Speaking seriously, it seems to me that Spurr has conceived and described magmatic processes and with convincing logic followed them to their legitimate and inevitable results. Exception must be taken, however, to his attempt to make all veins 'intrusive' in the same sense as 'dikes,' and to ignore entirely the effects of descending surface waters in the formation of the secondary ores. For many primary ores in regions of eruptive rocks his explanation is ideal and beyond criticism. It is not apparent, however, how we can escape the conclusion that both ascending and descending waters which long ages ago lost their line of descent from magmas must be constantly at work dissolving, transporting, and re-depositing ores and minerals. And there seems to be something more than suspicious in the constant presence of such waters and of the richer ores within 2000 ft. of the present surface, and the great scarcity of both of them below some such depth.

Another question not quite clear in my mind is as to the method by which most of the volatile watery vapor is to be retained within a cooling and differentiating magma only until differentiation is completed, and why at that particular time "all the accumulated water in the magma" (the aqueous residue), should deposit quartz veins and ores, and then, having "lost most of its heat" and "left behind nearly all of the elements with which it was associated," find its way to the surface and mingle "with the great body of surface and shallow-seated waters which has been so plausibly regarded as the accumulated residue of all crystallized magmas." Why should not some of this water begin to escape upward to the surface as soon as the catastrophe occurred that made differentiation possible in a particular unclassified magma? And what prevented those ascending hot vapors from transporting and depositing ores in the manner usually ascribed to ascending hot waters and vapors?

Is it not a lamentable fact that workable sulphide ores do not extend to great depths? Would they not continue downward practically unchanged, or richer; nay, should they not be encountered at considerable depth and followed to far greater depths if they were truly crystallized magmas?

If it be true that acid magmas possess greater mobility and fluidity than basic magmas, and if because of this fact they solidify nearer the surface, how shall their products be distinguished from the quartz veins and silicious rocks deposited by meteoric waters in circulation in the same zone. Or is Van Hise mistaken in his statement that "of the substances deposited in the belt of cementation quartz is undoubtedly the one which predominates over all others. The one great process in the belt of cementation is silication. * * * Hence it is highly probable that silicic acid is the dominant constituent contained in downward percolating waters. Therefore we have a source both for the deposited quartz and for the process of silication which forms the silicates."†

Another common feature of veins that does not seem to be readily explained by Spurr's theory is that of 'crustification.' This phenomenon is by no means universal, and is more frequently exhibited by genuine fissure veins, that is, those formed in open cracks in the rocks; yet it is also often seen in veins of substitution in shear zones where the rocks are so crushed that it is doubtful whether open spaces could ever have existed. In the latter instances there have been successive periods of rock replacement, and the resultant banding is seldom as minutely and beautifully parallel as in the filling of spaces of discision.

Personally, I am not yet satisfied that some of the richer secondary sulphides, like chalcocite, are ever formed in nature except from sulphate solutions. And since magmatic vapors and hot spring emanations are characteristically alkaline, while descending waters are acid, the very fact of the existence of such ores in a vein indicates the agency of descending waters; and the other phenomena are usually in concordance with that supposition.

In view of Spurr's opening plea for an indulgence until he presents his full discussion and "illustrates" it with facts and specific instances, it is hardly fair to urge further objections at this time. No doubt

† "Genesis of Ore Deposits." A. I. M. E., 1901, p. 332.

he will meet most of them in such manner as to shake to their foundations many of our most thoroughly established theories. And since to no one writer do I feel under greater personal obligations, so much the more readily will I lay aside cherished beliefs and adopt the new ones when complete and satisfactory proof is presented.

Minneapolis, March 6.

Biographical Note.

The Editor:

Sir—I notice in your issue of February 29, under the above heading, you mention the death of W. R. Boggs, Jr., who you say "met a tragic death in Mexico, being stoned by a mob of workmen clamoring for their wages." Mr. Boggs was the superintendent for the Topia Mining Co. at Topia, in Durango, Mexico, and in his death the company suffered the loss of a man whose energy, good judgment, and technical ability it will be hard to replace. I was in Topia making an examination of the company's property, and prior to his death, which occurred during my stay, I was with Mr. Boggs much of the time; but he was killed late at night while trying to eject, unaided and unarmed, a number of drunken *peones* from the company's mill. The rumor that the murder was committed by a "mob of workmen clamoring for their wages" was circulated at Durango by a discharged bookkeeper named A. B. Pettersen. The murder took place a day or so before the regular pay-day, and the men were paid off in full at the usual time.

I may add, for the benefit of mining men operating in Mexico, that two of the principals were finally caught, and the company has the assurance of the authorities that they will be promptly executed.

A Curious Accident.

The Editor:

Sir—A rather extraordinary accident happened in this camp the other day, and as it may be of some interest I shall describe it. Two mining men were examining some rock from the collar of an assessment hole. They had completed their work and were about to leave, when one of the parties picked up a small piece of ore and, carrying it up to where he had been breaking the others, struck it with a hammer; it exploded, blowing out one of his eyes and badly cutting the other. The other party, looking over his shoulder, fortunately escaped with a few cuts. The question naturally arises, why did this rock explode? It was a small piece, had been looked over before breaking, and it seemed the same as the other rock. The only explanation that seems possible is that at some time a stick of powder had been thrown on the dump, and in the hot sun this particular rock had absorbed enough glycerine to make it explosive, as there was no actual powder in the rock.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

In California, mining claims are located upon veins or lodes of quartz, or other rock, or veins of metal, or its ores, by posting thereon two notices, written or printed upon paper or some metallic or other substance, each to be posted in such a manner as to expose to view the full contents of the notice, and one of which shall be posted in a conspicuous place at each end of the claim. Such notices shall contain the name or names of the locators, the date of the location, and such a description of the claim or claims, by reference to some natural object or permanent monument, as will identify the claim.

Yosemite Mining Co. *v.* Emerson, 28 Sup. Ct. Rep. (U. S.) 196, Jan., '08.

A person who was employed on an idle oil claim part of the time as watchman, and at other times in pumping oil from the claim for use in the boiler, was entitled to a mechanic's lien for the value of his services in the pumping of the oil, under the statute providing that any person who performs labor in a mining claim, or in or upon real property worked as a mine, either in the development thereof, or in working therein by the subtractive process, has a lien thereon. But for his services performed as watchman, he could only hold the owner liable personally.

Donaldson *v.* Orchard Oil Co., (Cal.) 92 Pac. 1046, Oct., '07.

The 60 days within which the locator must perform his work begins to run from the date of the discovery of mineral and posting his discovery notice; and a locator cannot extend his time to do his work by changing the date on his discovery stake, or by renewing his notice of discovery. There cannot be two discoveries of the same thing by the same person, and the law having fixed the time in which the work must be performed, the locator has no power or authority to extend or enlarge that period for his own convenience. If the discovery shaft is not completed within the legal time, it is mere folly to pull down the old notice and put up another of a later date, as the 60 days begins to run from the date of discovery, and no self-serving act of the locator can enlarge the time. The exact rule may be stated thus: The locator is not permitted to re-enter and oust himself, predicating such re-entry and ouster on his own delinquency, and permitting him to re-enter and re-oust himself periodically to save the necessity of developing his claim. To permit the original locator the power within himself to make effectual a forfeiture arising from his own delinquency by perfecting a relocation, is to place in his hands the extraordinary privilege of holding mineral lands perpetually without doing any location work whatever.

Ingemarson *v.* Coffey, (Colo.) 92 Pac. 908, Dec., '07.

The re-location of an abandoned lode claim must be made by sinking a new discovery shaft and fixing new boundaries in the same manner as if it were a location of a new claim; or, in lieu thereof, the re-locator may sink an original discovery shaft 10 ft. deeper than it was at the time of the abandonment. No less work, and work which is not a substantial compliance with this provision, will amount to a re-location of an abandoned lode claim.

Ingemarson *v.* Coffey, (Colo.) 92 Pac. 908, Dec., '07.

A person will not be permitted to re-locate a claim because of the failure of the former locator to give the notice required by the mining district regulations, where he had knowledge of the location, and the exact boundaries of the former location were pointed out to him; and where the ground embraced within the exterior boundaries of the claim attempted to be located, was the same ground included within the exterior boundaries of the former location.

Yosemite Mining Co. *v.* Emerson, 28 Sup. Ct. Rep. (U. S.) 196, Jan., '08.

FOOTHILL COPPER BELT OF THE SIERRA NEVADA.

Written for the MINING AND SCIENTIFIC PRESS
By JOHN A. REID.

It is a lamentable fact that the literature of mining geology contains so little about the copper belt in the foothill region of the Sierra Nevada. This lack of full and proper description is all the more to be regretted on account of the great value of these deposits. In order that more attention be given to this region by those concerned in legitimate mining, and in view of the fact that some of the essential geological features of the belt have not heretofore been recognized, this brief paper, beginning a complete study and description, is offered for use at the present time. Geological work on the south half of the belt is greatly hindered by the absence of topographic maps, and the United States Geological Survey should be requested to complete the field-work south of the Jackson quadrangle. The Survey should also, as soon as possible, give us monographs on both the Copper Belt and the Mother Lode.

The more important papers dealing with the Foothill Copper Belt are listed below.[1] Of these it is very unfortunate that the ones on Pine Hill and Copperopolis are the sole representatives of detailed work. The folios of the United States Geological Survey, with the exception of the Redding, merely note the existence of copper at a few points.[2]

Before discussing the immediate subject of this paper, I desire to call attention to a distinction between certain groups of geological facts relating to mining, a distinction that I believe should be made by mining geologists whenever possible. The complete set of facts about any mining property consists of two more or less well defined classes: (1) Those broad and fundamental relations between structure, rocks, and ore, the character of deposit, and so forth, that can readily be grasped and immediately used by the operative miner; and (2) those more minute and technical details of petrography, mineralogy, genesis of ore, and so forth, that, while ultimately vital to a full grasp of the deposit, are not at once necessary to the practical worker. If this clear distinction be always made, so that the non-scientific man be not confused by a wealth (to him) of unnecessary details, the recognition of the value of geology to mining will become more universal. This paper aims to present, as a preliminary study, some of the facts that are vitally necessary to a proper understanding and development of the copper belt, and which may readily be grasped and used by miner or prospector. Not only are these facts stated, but also the details proving them are presented.

[2] The folios of the U. S. G. S. that cover any part of the foothill copper belt, from north to south, are: Smartsville, Sacramento, Placerville, Jackson, and Sonora. The Redding folio describes the deposits of Shasta county.

The foothill copper belt of the Sierra Nevada is a distinct part of the greater copper belt of California. It extends in a northwest-southeast direction along the foothills of the Sierra a few miles west of and parallel to the Mother Lode. The length is about 250 miles, reaching from Yuba county south into Fresno. Farther north the line of copper deposit turns northeastward into the summit region of the range. The important deposits of Shasta county are on the line of the foothill belt but separated from it by the Sacramento valley. South of Fresno county scattered copper ores are found, but our knowledge of them is very fragmentary. In fact, the information concerning the belt under discussion is yet so slight that it is impossible to formulate any broad generalization. Whether or not the belt posssesses unity as a province of any class, metallographic, petrographic, or structural, is yet to be settled. The general geologic features of the northern half are presented in the several folios of the United States Geological Survey. The southern half, which is probably the more important, is the one forming the main subject of this paper.

A few miles south of the Jackson quadrangle lie the important Copperopolis and Napoleon mines, with many promising properties near-by. About 25 miles southeast of the former place, the copper belt enters the west side of the Sonora quadrangle, the southwest corner of which it crosses. South of this area, in the region untouched by the Survey, lie the important mines of Mariposa and other southern counties. There are certain important geological conditions throughout the belt south of Campo Seco that tend to establish a definite unity within this portion of it. Further study will probably extend such unity to cover the whole. The important features to which I desire to call attention are as follows:

1. The foothill copper deposits occur in a struc-

Copperopolis, Looking Southeast.

The Gravestone Slates of the Copper Belt.

tural belt of which the most prominent feature is a weakness of the rocks. A complete investigation shows two rock-groups, distinct in time and physical characteristics. The earlier of these consists of the relatively abundant weak schists and slates; the later is composed of a series of massive igneous intrusives. Much variation in hardness exists in the earlier rocks, yet the belt as a whole is notable for the weakness of the component lithological units. More particularly, the older group embraces the various metamorphic tuffs and volcanics, now occurring as amphibolite schist, chlorite schist, meta-andesite, both schistose and massive, with all their variations, and the several facies of the Mariposa slates, from ordinary fissile black clay-slate to mica and andalusite schist. The ores occur at different places within all of them, irrespective of their exact petrographic and chemical nature. It is evident that, of the two possible factors governing ore deposition, the structural weakness of the rocks is the essential one, and that the precise characteristics of them as individual species is of secondary importance. At the same time, in the middle portion of the belt the physical qualities of the sedimentary and igneous schists appear to have exercised a differential control upon the basic intrusives responsible for the ore. These intrusives, and the connected ore deposits, follow the rocks of igneous origin, such as the meta-andesites, rather than the clay slates. In the southern part of the copper belt the mines are in schist derived from the Mariposa slate.

2. In the central part of the copper belt, from Campo Seco south to the Stanislaus river, there exist two lines of ore deposition, one following the east and the other the west side. The Campo Seco and Napoleon groups are on the west Copperopolis and the mines north of Littlehales are on the east.[3] Between these lies a broad belt of Mariposa slate, usually devoid of copper. These rocks are comparatively tough, and offer a greater resistance to igneous intrusions than the schistose tuffs and flows. A good example of this is found a few miles north of Copperopolis, where a serpentine dike has bowed and contorted a thin slate tongue but was unable to break through, though readily penetrating the adjacent schist. North of Campo Seco and south of the Stanislaus river it is yet uncertain whether or not the same conditions obtain. The two lines of deposit probably mark the places of maximum fracturing and igneous intrusions, and therefore of greatest ore deposition.

3. The structural weakness of the older slates and schists has been a feature of the range from early geological time to the present. The result of this has been the intrusion of a series of igneous rocks, with some of which ore deposition is connected. A glance at the Jackson and Sonora folios will show the distribution of the larger intrusive masses. There is a complex history of these, only a part of which is yet entirely clear. The whole series may be divided into two parts, upon a basis of time, petrographic, and structural relations. The earlier rocks are of plutonic habit, chemically basic or ultra-basic, and of very dark or black color. The grain is from fine to very coarse. They occur typically in long dike-like areas and true dikes, whose maximum extension is prevailingly parallel to the schistosity and therefore to the lines of greatest weakness of the pre-existing rocks. A few intrusions cross the foliation planes, but only under exceptional local conditions. The later intrusives are chemically acid, of both granitic and porphyritic habits, and usually of light color. The granitic rocks show few dike-like forms, but are commonly in rounded bosses and larger irregular domes having no orientation whatever to the surrounding schists or slates. A few rare granitic dikes do occur, as at Copperopolis. The porphyritic rocks, represented by quartz-porphyry in the copper belt, are always in dikes, and are few in number. The rounded forms of the acid plutonic are probably due chiefly to the viscosity of the acid magma and its inability to follow small openings. A weak belt of rocks may have become relatively stronger at the time of intrusion, due to compressive forces set up by larger masses of grano-diorite to the east. This would tend to prevent the formation of dikes, and may have been a real factor.

4. The massive igneous rocks are vitally important in the study of the copper deposits, as some of them are connected with the origin of the ores. These rocks, in order of relative age, are:

CLASS I.

1. Serpentine, from percolatite.
2. Pyroxenite and hornblendite, including some diabasic rocks.
3. Gabbro.

CLASS II.

4. Granite and granodiorite.
5. Quartz-porphyry.

The relative age of the last is yet uncertain. It is provisionally placed latest by reason of its possible relations to the acid plutonic.[4] It must not be confused with some older meta-rhyolite, that occurs in large amount in Gopher Ridge, at Campo Seco, and elsewhere in the meta-andesite formation. These older quartz-porphyries are among the earlier rocks of the copper belt. With the exception of a few yet obscure relations of the quartz-porphyry to adjacent rocks, from Campo Seco south the acid intrusives are distinctly later than the copper ore. Campo Seco itself has not been sufficiently studied by the writer to warrant any precise statements in this connection.

Of the first class of igneous intrusions, the serpentine is earlier than the copper ore, the gabbro later, and the hornblendite and diabase connected genetically with the deposits. The grano-diorite is later, but is in its turn related to deposits of auriferous pyrite in a quartz gangue. It is a probable condition that the gold-bearing quartz veins of the Mother Lode are connected with the acid plutonic intrusive.

[3] See Jackson Folio. U. S. G. S.

[4] The main argument for a later age of the quartz-porphyry is based upon its texture compared with that of the grano-diorite. The plutonic rock, now well exposed on the surface, crystallized from a molten condition at great depth; the quartz-porphyry solidified relatively near the surface. The two rocks now exist side by side, so that it becomes obvious that the porphyritic rock was intruded after the plutonic had cooled and much of the overlying material carried away by erosion. After a complete study of the intrusives the quartz-porphyry will undoubtedly be placed in a class by itself.

No deposits of ore undoubtedly associated with the quartz-porphyry are known to the writer.

5. The copper belt is characterized by a small amount of secondary ore, either oxidized or sulphide. The Pocohontas mine is an exception. Because of local fracturing and opening of the ground to vadose waters by an intrusion of grano-diorite, a zone of oxidized ore extends from the surface down for 90 ft., below which a small amount of secondary sulphides were formed. The causes of this condition of little oxidation are two. The easy erosion of the soft rocks of the belt has allowed the removal of surface ores at a comparatively rapid rate. Also, the tangential forces of compression present in the range have prevented the formation of an extensive vadose circulation, with resultant secondary ores. The second cause seems the more important. It is often the case, as at Copperopolis, that large bodies of original sulphide ore are capped by an inconspicuous gossan. The large bodies of nearly pure pyrite with low copper content have an extensive limonite cap, but such deposits are not typical of the belt.

6. Because the rocks containing the copper ore are foliated, the type of deposit consists of veinlets and stringers of the sulphides along the planes of schistosity. The aggregate of a particular group of ore stringers is commonly a lens or shoot. Not enough is known about the details of the great number of deposits to warrant a closer statement than this. At both Campo Seco and Copperopolis, as examples of comparatively well opened mines, the orebodies are usually called lenses, yet it is entirely possible that they are not lenses but true ore-shoots, reaching unbroken to a great depth. Some of the Mariposa county mines exhibit a different form. The Pocohontas ore is due to the metasomatic replacement of a basic dike and adjacent schist by sulphides of iron, copper, and zinc. The Great Northern mine near-by contains ore due both to a replacement of a basic dike and to the deposition of sulphide along the parting planes of the country. At the Cavan mine, a few miles south, the ore occurs as veinlets in the schist along the line of a basic intrusive, but the shallow workings are insufficient to show all the conditions of ore deposition. The essential point, in at least the south half of the copper belt, is the genetic relation of the ore to basic intrusives; the precise form of the orebody is of secondary importance.

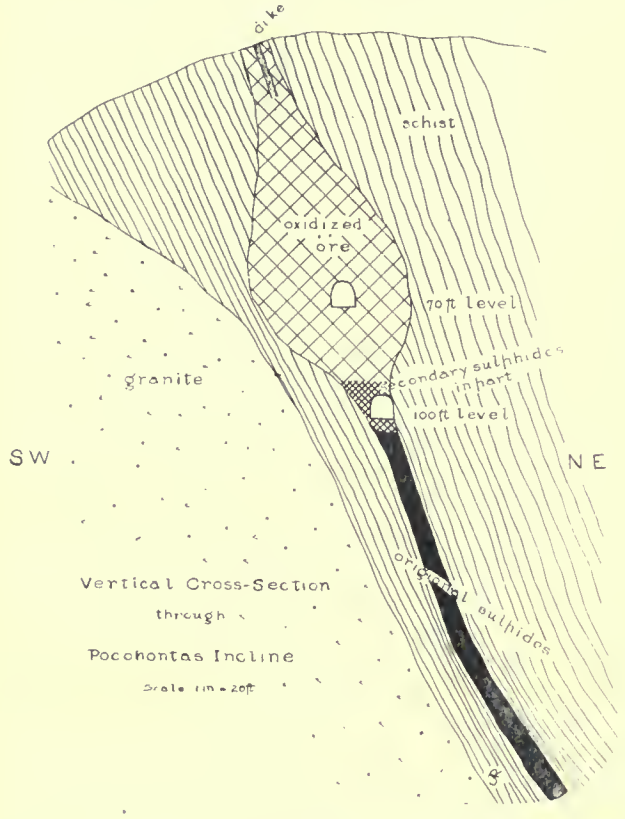
7. The question of depth is one always vital to the economic value of an ore deposit. Some of the irregular masses of low-grade pyrite of obscure origin have not kept their value with depth, but the mines exploiting deposits typical of the belt show no tendency to pinch out. The ore at Campo Seco has always varied as the workings have been extended, but the average tenor remains about the same. At Copperopolis the ore varies most in its physical condition; the change in copper content from top to bottom is little and irregular. Further, a winze sunk from the lowest level has cut a good body of high-grade chalcopyrite. This ore may be the apex of a new lens, or the downward prolongation of the ore-shoot above, displaced to the east by a nearly horizontal fault. The Napoleon shows good ore in the bottom. The comparatively shallow depths reached by the more southern mines have disclosed not a lessening in value, but rather a steady content of copper and little change in size of orebodies. None of the mine openings are yet of sufficient magnitude to bring to light any direct evidence beyond that already cited. Hence we are thrown upon a consideration of general geological relation for a more comprehensive view of the question. There is this to offer: The main mass of the ores are unaltered sulphides; they are connected genetically with deep-seated intrusives; the country rock, whose fissility often affects the ore deposition, maintains its character as a schist to great depths; the deepest mines on the Mother Lode show the schists and slates in their lowest workings identical with those on the surface. There is no reason, therefore, for expecting the copper ores to pinch out, but there are several good reasons for anticipating the existence of ore far below any point yet touched. Those large irregular masses of low-grade pyrite are excluded from these remarks, for the writer, of his own experience, knows nothing about them.

To illustrate the various statements made above, brief descriptions will be given of a few typical mines. Of these Copperopolis stands pre-eminent as a type in all details save the mineralogy of the ore.

Copperopolis.

The weak rocks of the copper belt at Copperopolis are embraced in the meta-andesite formation. The ore occurs as lenses or shoots in a chlorite schist, a local modification of the rock-mass. Intruded into the earlier formation are serpentine, hornblendite, gabbro, and grano-diorite. The serpentine, including talc, often framing the west wall of the ore zone, is older than the ore, as seams and films of the sulphides are found along the gliding planes within it. The hornblende is always within the ore-bearing schist and contains chalcopyrite as an original constituent. Its physical appearance indicates that it has undergone about as much compression as the ore. The gabbro, occurring only in one small boss, appears later than the ore, as it cuts directly across the main line of deposit but contains no traces of copper. It also fails to show the results of as great compression as that experienced by the ore and hornblendite. The grano-diorite occurs as a series of tongues and larger masses intruded into the ore zone, in which it has caused both physical and chemical changes. In those parts of the Union mine best opened the seams of ore have been displaced by a great number of small faults dipping gently to the east. Each individual fault is characterized by a shifting of the foot-wall a few inches to the east; the nature of the movement is therefore that of a direct thrust, with the peculiarity that the foot-wall and not the hanging wall has been moved by the active force. This series of small movements is due to the lateral pressure caused by the intrusion of a tongue of grano-diorite. The accompanying photograph illustrates this feature. Other faults also are necessary in the complete dynamics of these intrusions, and they are not rare.

Such faults are found crossing the schist nearly at right angles to the strike, with nearly vertical dip, and with their movement depending upon the position of the intrusive tongue. That wall of each of these faults that lies nearest the grano-diorite has moved outward, or eastward, as the rocks are actually placed. A few of these dislocations are shown in the photograph. The general effect upon the ore



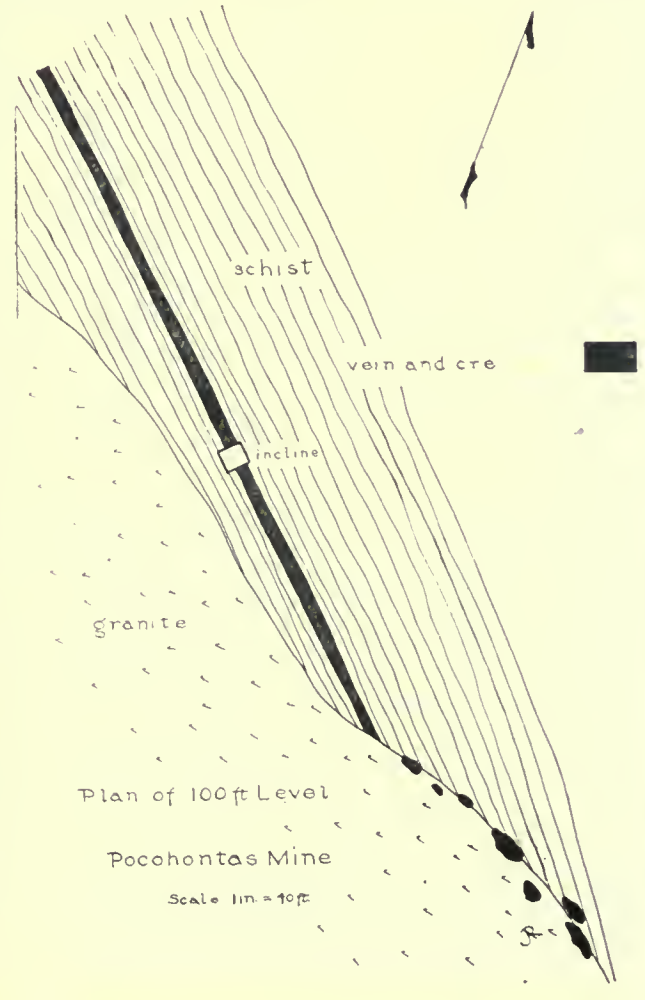
has been to decrease the angle of dip of the ore-shoot, while that of the individual seams has not been altered. The chemical effect of the acid intrusive is no less marked. The normal ore is noted for its lack of free silica and with sulphides in sharply defined seams. Where the grano-diorite has pushed its way into the ore the chalcopyrite has been recrystallized into irregular grains and masses in a gangue of quartz, calcite, and chlorite of different grain from that of the original schist. A photograph shows the top of a tongue of the plutonic with the ore seams curved around its periphery. The ore directly on the tongue is much silicified; that a few inches away less so; that a foot distant is little altered except where cut by quartz veinlets. Much pyrite with not a trace of copper is present within the body of the tongue. The metal is present near the outer limits of the intrusion, where some absorption of ore has occurred. The fact that pyrite is present as an original constituent in the upper portions of the grano-diorite is important. This mineral is dissimilar to that associated with the chalcopyrite, as it contains gold but not copper. It is present chiefly in the upper parts of the intrusive tongues, which are also more silicious than the normal phase of the rock. Veinlets of quartz, and quartz with feldspar, project upward from the intrusion into the adjacent schist and ore. Quartz-calcite veins also are found on another part of the mining ground. The upper portions of the granitic magma were thus rich in silica, carbon dioxide, vapors containing some form of sulphur, probably hydrogen sulphide, and gold, but no copper in appreciable quantity. Elsewhere on the surface over known intrusions of the acid rock there are found veins and irregular masses of auriferous pyrite with quartz. Such pyrite is usually coarsely crystalline and different in appearance from the same mineral as found in the copper ore. For full particulars on Copperopolis the reader is referred to the larger paper.[5]

Pocohontas.

This group of mines is situated in Mariposa county near Lewis postoffice, east of Merced. There are several important features of the copper belt exhibited by these deposits. The prevailing rock is andalusite schist, of the Mariposa slate formation. It is intruded by basic and acid plutonics, the petrography of which is not yet worked out, nor is it essential to the needs of the present paper. The basic rocks appear to be both diabasic and ultrabasic, with possible gradations. The acid rocks have but the one usual representative, a granitic one, which will here be referred to as granite.

The chief properties are the Pocohontas and Great Northern. Across the land owned by the present company there are three well defined lines of basic igneous intrusions. Others occur still farther west. On the east line lies the Pocohontas; on the west about a mile distant lies the Great Northern. The middle line shows no ore at this place, as the covering of alluvium masks the rocks, but along its southward extension ore is found. At the Pocohontas the

5 'The Ore Deposits of Copperopolis, California.' *Economic Geology.* Vol. II, No. 4, 1907.



schists strike almost northwest and southeast, dipping about 70° east. Intruded along the cleavage planes is a narrow dike of rock much like a diabase in hand specimens yet having the appearance of a hornblendite in some coarser grained facies taken from the surface. Below the 100-ft. level the ore is in its original condition and shows 4 ft. of practically solid sulphides between clean schist walls. The ore has metasomatically replaced the dike and some schist. The actual thickness of the dike is yet undetermined, as material clearly recognizable as such is found only with the gossan on the surface. Above the 100-ft. level the sulphides are present for 10 ft., on top of which is a large body of carbonate and silicate of copper. There is a maximum width of perhaps 40 ft. of this material at the 70-ft. level, though not more than 20 ft. is workable ore. The oxidized body narrows toward the surface, where comparatively few stringers of green ore in an iron-stained schist indicate the presence of the deposit. Below the 100-ft. level in the shaft the vein descends in a uniform manner, both in respect to copper content and size. The dip changes somewhat, due to the pressure exerted by the intrusive granite. The section presents these features. On the level to the north no particular change in the vein occurs; to the south for 100 ft. from the shaft some secondary sulphides are present to a depth of 140 ft. Farther south the vein and ore are cut off by the granite. The granite-schist contact here strikes about west-northwest, but varies at different points. South of the end of the unbroken vein are found bunches of ore scattered along the contact of granite and schist, some of which have considerable value. It is these occurrences that have caused the belief that the main orebody is a contact deposit. The section shows this condition. The ore is a mixture of chalcopyrite, pyrite, sphalerite, and possibly a little pyrrhotite, with some gold.

The Great Northern mine is situated on a deposit similar to that of the Pocohontas, but differing from it in a few noteworthy particulars. A dike of ultrabasic rock occurs within the boundaries of the ore zone. It is a hornblendite or closely allied species, but is now so altered by the vein solutions that a precise determination is yet to be made. The ore is partly the metasomatic replacement of the dike and in part consists of veinlets and seams along the foliation planes of the adjacent schists. Nearly 40 ft. of schist is ore-bearing. The entire substance of the intrusive is not replaced, and the part remaining has not been reduced to an aggregate of radial bunches of a light colored amphibole in which the sulphides occur both finely disseminated and in larger discrete masses. In addition to the sulphides noted in the Pocohontas vein, arsenopyrite also is found in the altered amphibolitic dike. The ore in the schist shows little or no arsenical minerals.

The large granite intrusion that crosses this part of Mariposa county in a general east-west direction lies to the south of the Great Northern. South of the granite the copper belt continues and contains many promising properties. The Cavan mine lies about four miles south of the Pocohontas and shows similar conditions of ore deposition. The deepest workings of these mines are but a few hundred feet, and much development work is needed.

It is an interesting fact that at one other locality a granite intrusion cuts across the copper belt. The large area of this rock east of Sacramento lies within the boundaries of the belt, and has undoubtedly acted upon the copper deposits of that immediate region as it has done farther south.

Conclusions.

The conclusions to be drawn from the facts presented in this paper are not many, but they are important:

The foothill copper belt is one of weak schistose rocks whose precise composition is of secondary importance to their general weakness. Into them have been intruded at different times a series of igneous rocks of two main classes. The first consists of basic plutonics of different ages: the second is chiefly acid grano-diorite or granite. In the first class, hornblendite and allied species are genetically connected with the copper ore: the acid rocks are related to later deposits of auriferous pyrite and gold-quartz veins. The basic rocks are typically in dikes or dike-like forms intruded into the schist parallel to the line of maximum weakness. Hence the copper orebodies strike with the country rock and consist of veins, lens-shaped deposits, or ore-shoots in the schist. The ore consists essentially of original sulphides, little secondary material having been formed. A gossan is always present, but a small limonite capping does not necessarily mean a small body of ore below. The depth of the orebodies is unknown, but is probably great. The belt as a whole is badly in need of intelligent prospecting and mine development.

The ores of the Goldfield district in Nevada occur in the form of masses of shattered, altered rock of very irregular shape. The common gangue of the unoxidized ore is compact, almost flinty, quartz which in most cases has resulted from the silicification of dacite, rhyolite or andesite. Associated with the quartz in much of the ore are soft white substances which in most cases are either alunite or kaolinite or a mixture of the two. These are commonly called 'talc' by the miners. The ore contains pyrite, bismuthinite, native gold, and a brownish copper-bearing mineral having the general composition of tetrahedrite. Chemical analyses nearly all show a little tellurium and a small speck of sphalerite has been found in the Goldfield-Belmont ore. The best ore is characterized by concentric shells of ore minerals about greatly altered rock-fragments. An inner zone of free gold and quartz up to an eighth of an inch in thickness may be covered by a shell of tetrahedrite and this by an outer crust of pyrite. In the Florence mine similar fragments show first a shell of pyrite, then one of tetrahedrite, and finally a thick crust of quartz with native gold, tetrahedrite, and pyrite, and transfixed by needles of bismuthinite.

SIMPLE PROBLEMS IN AIR-COMPRESSION.

Contributed to the MINING AND SCIENTIFIC PRESS
By EDWARD A. RIX.

*Before we undertake to solve the problem that I shall present for your consideration, I shall give you some of the practical data on which my calculations are based.

During the last twenty years, I have kept a log of all the compressed-air plants I have tested, and also the actual performances of a great number, covering almost every kind of compressor and compressed-air motor or tool, and I have averaged all the indicator-cards taken from the various compressors used in mining work and compared the indicated horse-power with the actual power required, comparing this with the displacement of the compressed cylinders, I have concluded that for a safe and sane power factor, we must allow 20 hp. for every 100 cu. ft. of cylinder-displacement, to compress air from atmospheric pressure to 90 or 95 lb. receiver gauge-pressure at sea-level.

I have made my calculations on these pressures because they are the standard pressures now used for pneumatic work, and nearly every machine and motor is constructed for these pressures. Twenty horse-power means the power delivered at the shaft of the prime mover.

If you consult tables in any engineering magazine or trade catalogue on air-compressors, you will note that the power claimed to do certain work is much less than the figure which I give you, and in explanation it must be noted that these tables are theoretical, and do not take into account the mechanical efficiency of the compressor, nor losses due to volumetric efficiency of compressors. These figures are therefore misleading and should be avoided except in comparisons between one machine and another.

It is most unfortunate that the public is not given the results of working tests upon plants of all descriptions running under ordinary conditions, as such information is much more valuable than the records of official tests, which are usually made under special conditions by experts at the most satisfactory load—a set of conditions not often realized.

You must have a safe margin in your calculations, so that neither you nor those for whom you are installing a plant will be disappointed, and I therefore have given you 20 hp. per 100 cu. ft. of cylinder displacement as a figure that will never get you into trouble, and at the same time, it is not too generous. It may also be noted that it would be just as well in small plants to make no distinction between single and two-stage machines. By small plants, I mean up to 400 cu. ft. capacity.

Second: Remember that a compressed-air cylinder will never give a quantity of air equal to the volume swept by the piston, for the reason that such things as clearance, leakage, temperature, piston speed, etc., reduce the theoretical quantity so that it is best to estimate about 80% volumetric efficiency for the average mining compressor. Many do not give 60%, and some 90 per cent.

*An address delivered before the Mining Association of the University of California.

Third: In using compressed air at 90 lb. pressure cold, it will take 24 cu. ft. free air per minute to give one horse-power in plain slide-valve engines and 15 cu. ft. with good expansion-valve gearing; and between these two limits will lie all the various types of engines. If the air be re-heated, to about 300° F, it will reduce the above quantities about one-third. In one hoisting engine which I installed, having compound Corliss cylinders and where the air was heated to 400° F before entering each cylinder, it required between 7 and 8 cu. ft. only for one horse-power. Most mines, however, use cold air and prefer the power-loss to the trouble and expense of the installation and maintenance of re-heating apparatus.

Fourth: The tables set forth in the trade catalogues for the air-consumption of standard piston rock-drills are fairly accurate and are generally in terms of the compressor-cylinder displacement.

Fifth: For operating ordinary station and sinking pumps of the direct-acting type, which is the ordinary stock pump used in mining operations, it will be safe for you to calculate that one cubic foot of free air compressed to 90 lb. gauge-pressure will do 135 foot-gallons of pumping.

Sixth: Ordinary mining hoists have a mechanical efficiency of about 75 per cent.

Seventh: For the determination of sizes of pipe, losses of pressure, and terminal pressures for compressed-air transmission, I use the Johnson formula, which is:

$$P_1^2 - P_2^2 = \frac{0.0006 V^2 L}{A^5}$$

wherein P_1 = absolute initial air-pressure.
P_2 = absolute terminal air-pressure.
V = free air equivalent passing through the pipe.
L = length of pipe in feet.
A = diameter in inches.

This formula is quite simple to solve.

With these facts at hand, we can now readily calculate the problem to be considered, which is:

Problem.—Given a water-power distant 5000 ft. from a mine, it is desired to generate compressed air and transmit it to the collar of the shaft for operating purposes. The work to be performed is as follows:

One hundred tons of ore and waste to be hoisted in 20 hours.

Thirty gallons of water per minute to be pumped, either at a station or a sinking-pump.

Five 2¼-in. standard piston rock-drills to be operated.

Three air-hammer drills to be operated.

General Conditions:

Depth of shaft, 600 ft.
Weight of skip and rope, 1000 lb.
Weight of ore hoisted, 1 ton.
Initial air-pressure, 95 lb.
Final air-pressure, 90 lb.
Altitude, sea-level.
Geared hoist and unbalanced hoisting.

Required:

Size of compressor.
Diameter of air-pipe.
Brake horse-power.
Altitude factors.
Re-heating coefficients.

Note: In problems of this kind, we must reduce all of our requirements to cubic feet of free air, because free air is the basis for all power calculations.

To determine the free air required for hoisting: If 100 tons of ore and waste are to be hoisted in 20 hours, the hoisting will be done at the rate of 5 tons per hour, and as each load hoisted contains one ton, it follows that there will be a load hoisted every 12 minutes. Of course, we know that an absolute schedule of 12 minutes between hoists can scarcely ever be carried out, for the intervals may be shorter during one hour and longer during another, or stop altogether, but the only way to figure it, is on a regular basis, and after that is determined, allowance one way or another can be made for any irregularity.

The load being 2000 lb. of material and 1000 lb. of rope and skip, makes a total of 3000 lb. which is to be hoisted 600 ft. This 3000 lb. lifted 600 ft. will require 1,800,000 foot-pounds of work, or 54 hp. theoretical. Since the hoist has a probable efficiency of 75%, the 54 hp. theoretical becomes 72 brake-power actually required.

Using cold air, it requires, as we have mentioned before, 24 cu. ft. free air per horse-power. Then $24 \times 72 = 1728$ cu. ft. of free air, which the hoist will consume to make one lift. This, you will note, gives us direct results without taking into consideration the element of time or the dimensions of the hoist. If we made a hoist every 12 minutes and it required 1728 cu. ft. to make a hoist, then the compressor must furnish 144 cu. ft. free air per minute continuously, and we must have storage capacity sufficient to accumulate the air between hoists. Right here is the vital point of hoisting economically with compressed air.

Let us assume in our problem that we hoist at the rate of 300 ft. per min.: then it will take 2 minutes to make the lift, and the hoist will be lowering and idle during the next 10 minutes. During this 10 minutes the compressor is delivering 144 cu. ft. free air per min., or 1440 cu. ft. total, which must be stored.

If the hoist is none too large for the work, you will find that if the pressure in the receiver drops more than one atmosphere, or from 90 to 75 lb., the hoist will not operate in a satisfactory manner. Then, in our problem, if we must draw 1440 cu. ft. from the receivers at a drop of one atmosphere in pressure, the receivers must have a capacity of 1440 cu ft., and if the hoist is amply large so that it will still operate after the receiver pressure has dropped two atmospheres, or from 90 to 60 lb., then the receiver capacity can be one-half of 1440 or 720 cu. ft.; but it is not wise to go below this pressure, because it will affect too materially the pressure required for operating the other machinery.

For first-class work, install receivers having a capacity equal to the storage required at one atmosphere pressure. Large receivers cost less in proportion to their storage capacity than small ones; for example, a carload consisting of four receivers 54 in. diam. by 30 ft. long, containing about 2000 cu. ft., costs at the present time about $1600, while the same storage in ordinary receivers 48 in. diam. and 12 ft. long would cost about $2200. It is better to invest more money in receivers and less in compressors, because the smaller compressor takes less power at the peak, and most power bills are figured on a constant peak.

If you install a plant and the receiver capacity is too small, you can always determine the proper quantity of storage by running the compressor with the unloader cut out, and if the receivers blow off between hoists and the pressure drops more than 15 lb. during hoisting, add more receiver capacity until it will not blow off nor drop more than 15 lb. If you arrive at the point where it does not blow off and the pressure does not fall 15 lb., then slow down the compressor until the desired drop is reached, and you will be operating your plant at the most economical point. Then cut in the unloader again and let it work when it will. An unloader only saves wear and tear on the compressor where you buy power at the peak load, as happens in most cases, but does not affect your power bill.

Let us go back to our problem. We have found that 144 cu. ft. per min. is required for hoisting. Now, while we have allowed 4 hours in 24, or 1 hr. 20 min. on each shift, for hoisting and lowering men, timbers, supplies, etc., it is entirely probable that at least once every hour someone will be going up and down the shaft, and it would be practical therefore to say that the hoist would handle 6 loads per hour, instead of 5, and we must therefore add 20% to the hoisting requirement, making say 175 cu. ft., instead of 144.

To determine the amount of compressed air required for pumping: For pumping 30 gallons per minute 600 ft., requires 30×600, or 18,000 foot-gallons of work. If one cubic foot of free air at 90 lb. gauge-pressure will give 135 ft.-gal., we shall require 133 cu. ft. free air for the pumping. This requirement is constant.

To determine the amount of compressed air required for drilling: Five 2¼-in. rock-drills will require 50 ft. free air each, or 250 cu. ft., and three air-hammer drills will require 25 cu. ft. each, or 75 cu. ft. To get these amounts, take about 80% of the requirements as stated in rock-drill catalogues, which always give quantities in compressor-cylinder displacement, which do not deliver on an average within 20% of their displacement, except in large machines.

Our total requirements will therefore be:

Work.	Cubic feet.
Hoisting	175
Pumping	133
Drilling	325
Total	633

This 633 cu. ft. does not take into consideration any ordinary pipe-leakage in the hoisting works and below ground. In conducting this air from a distance, for our problem calls for a transmission of 5000 ft., it would be well to allow for a leakage of 5% on the entire system. This would bring our requirement up to 665 cu. ft, and if we allow that our compressor will give a volumetric efficiency of at least 80%, we must have a cylinder displacement of 830 cu. ft. per minute.

You will remember that our power factor was 20 hp. per 100 cu. ft.; consequently we must have 166 hp. delivered on our water-wheel shaft to drive this compressor.

Finally, we must determine the size of the pipe, allowing 5 lb. drop in pressure for loss by friction. You will remember the formula:

$$P_1^2 - P_2^2 = \frac{0.0006 V^2 L}{A^5}$$

P_1 the initial pressure absolute $= 95 + 14.7$, or 109.7, and its square is 12034.

P_2, the terminal pressure, we have stated shall be 5 lb. less than the initial, or 90 lb., or 104.7 absolute, and its square is 10962.

The difference between these two or

$$P_1^2 - P_2^2 = 1072.$$

Substituting this in our equation, and also the values for L and V, we have

$$1072 = \frac{6 \times 5000 \times 633 \times 633}{10{,}000 \times A^5}$$

Reducing, we have $1072 \times A^5 = 3 \times 633^2$, or

$$A^5 = 1121$$

$$A = 4\text{-in. pipe.}$$

We have now to figure the size of the compressor required. If you happen to have tables and catalogues at hand, it will be an easy matter to look up a satisfactory compressor having a displacement of 830 cu. ft., but if such literature is not at hand, the size of the compressor may be determined as follows:

It almost goes without saying that you would select a two-stage compressor for anything over 400 cu. ft. capacity. This two-stage compressor will have a low-pressure or gathering cylinder, wherein the air is compressed to about 25 lb., and a high-pressure cylinder, where the air at 25 lb., after it has been cooled, will be compressed to 90 or 95 lb. pressure. The reason a two-stage machine is selected is because it has a higher volumetric efficiency, requires less power to operate it, is easier to lubricate on account of lower temperatures, and has less strains on the mechanism.

The first thing to consider is the speed at which you will operate the compressor, and this will be dictated by many things. If you have a limited amount to expend, you will naturally select as high a working speed as possible, because the higher the speed, the smaller the compressor. Again, you may have to take the future into consideration, and you may want more air when the shaft goes deeper or more water is encountered. You would then naturally select such a speed as would give you the margin of additional power required.

You may take 150 r.p.m. as the maximum for compressors from 400 to 1500 ft. capacity, and 100 r.p.m. as a speed that will give you a 50% margin for the future, so let us assume that the mine in question has a future, and take 100 r.p.m. If our requirement is 830 cu. ft. per min. we shall then require an intake or compression cylinder that will give us 8.3 cu. ft. per revolution, and inasmuch as the cylinder is double-acting, that is, makes two displacements per revolution, the cylinder must have a capacity of 4.15 cubic feet.

Experience dictates that the average compressor-cylinder is built for the following strokes and capacities:

Stroke in inches.	Capacity in feet.
6	up to 50
8	" 100
10	" 200
12	" 500
16	" 700
18	" 1500
24	" 2500

Our compressor will therefore be best suited by an 18-in. stroke, or 1.5 ft. If the capacity is 4.15 cu. ft. and the stroke 1.5 ft., the area of the cylinder will be: $4.15 \div 1.5 = 2.75$ sq. ft., or 397 sq. in., which is the area of a 22½-in. cylinder. The low-pressure cylinder will therefore be 22½ by 18 inches.

It is evident that if we have two cylinders to do our compressing, there is no good reason why one cylinder should do more work than the other, and there is a very good reason why the work performed by these cylinders should be equal, namely, because the total work and temperature developed will be at a minimum. As an explanation would lead us into mathematics, you must take the statement as a fact. There is also the mechanical reason that the strains on the machine will be at a minimum, and if you construct the compressor of the duplex type, both sides will be alike except as to the cylinders. It can be shown easily by algebraic method that if our two cylinders perform equal work, the intermediate pressure must be a mean proportional between the initial absolute pressure and the final absolute pressure, and the cylinder ratios will be as the ratios of either the high or initial absolute pressure to the intermediate. In other words, to put this in such shape that you will easily remember it:

If P = absolute initial pressure
P_1 = absolute intermediate pressure
P_{11} = absolute final pressure

then $P_1 = \sqrt{P \times P_{11}}$

Take our example: Our initial pressure is atmospheric or 14.7 lb. absolute. Our final pressure is 95 lb. gauge or 109.7 absolute. The intermediate pressure will then be $P_1 = \sqrt{14.7 \times 109.7}$, or 40 lb. absolute, or 25.3 gauge pressure. Our proportion then stands thus: 14.7 : 40 :: 40 : 109.7, which represents a ratio of $40 \div 14.7$, or $109.7 \div 40 = 2.74$.

The cylinder ratios will therefore be identical with the pressure ratios, and our high-pressure cylinder will have a capacity of $1 \div 2.74$ of the low pressure. The strokes being the same, the area of the high-pressure cylinder will be $1 \div 2.74$ of the low-pressure, which was 397 sq. in. Dividing this by 2.74, we

have 145 sq. in. as the area of the high-pressure cylinder. This corresponds to a diameter of 13½ in. The compressor will then be a 22½ by 13½ in. with 18-in. stroke, and you will be justified in taking the nearest size to this that the manufacturers can supply.

You will note that as the altitude increases, the initial absolute pressure diminishes, and as the final pressure remains the same, the pressure-ratio grows larger as the altitude increases. For example: at 10,000 ft. the atmospheric pressure is 10 lb. instead of 14.7 lb., and if you go through the same calculations that we have just made, you will find that the cylinder-ratios will be 3.3 instead of 2.74, and this will make the high-pressure cylinder only 12½ in. diam., instead of 13½ diam., and the intermediate pressure will be 18.3 lb. instead of 25.3 lb. Such a compressor would not, however, be able to do the work contemplated in the problem considered, for the reason that while the weight of air necessary to do work remains practically the same for reasonable altitudes, the capacity of the compressor diminishes as the altitude increases. It is true the volume remains the same, but it has not the weight, and therefore you must increase the size of the cylinder required at sea-level by the ratio between the ratio of compression at sea-level and the ratio of compression at altitude.

In our problem, the ratio of compression at sea-level is 7.5, and the ratio of compression at altitude of 10,000 ft. is 11. The sea-level compressor must be increased therefore 11 ÷ 7.5, or 1.47 times, to give the same weight of compressed air at 10,000 ft. altitude, or to put it even more simply, it will take 11 strokes of the same sized compressor piston at 10,000 ft. altitude to give the same compressed air or to do the work that 7½ strokes will do at sea-level. In our problem this would make a low-pressure cylinder of 27 in. instead of 22½ in., and a high-pressure cylinder of 15 instead of 13½ in. In other words, this altitude compressor must be nearly 50% larger to do the same work.

A proper understanding of these simple calculations will enable you to check compressor sizes and proportions, and no one could furnish you with a sea-level compressor for an altitude, nor the reverse. We have assumed 80% volumetric efficiency in this problem, but if the compressor happens to be a slow-speed mechanical-valve machine, 90% could be assumed. The figures I have given are safe and taken from average plants, and it will be necessary for you to use your judgment in assuming a higher or lower factor.

To determine the amount of compressed air required for re-heating: It is practical to re-heat air from 300 to 400°F in various ways, and great economy is realized, especially for pumping and hoisting, and if it is possible you may reduce the quantities of cold air that we have figured for this character of work by the ratio of the atmospheric to the compressed-air temperatures absolute. Thus, if the atmosphere is at 60°F or 520° absolute, and the compressed air is used at 300°F or 760° absolute, then the volume of cold air for your work may be taken at the ratio of 520 ÷ 760, or about 70%, thus making a saving of 30 per cent.

In conclusion, let me caution you about being led astray by the will-o'-the-wisp 'efficiency' when you come to choose between compressed air and some other power to do mining work. 'Utility' should always be the standard for comparison. It is seldom that any set of conditions calls for the exclusive use of one kind of power, and it is not good engineering to make an installation the victim of any fad or prejudice. Whether it be steam, electricity, water-power, or compressed air, or a combination of any or all of them, let the sole and only qualification be determined on the basis of commercial efficiency.

The precipitation room of the cyanide plant at the Portland mine, Colorado, contains 18 rows of zinc boxes, each row having six compartments 4 by 4 by 4 ft. and pyramidal in shape at the bottom. A 14-mesh wire screen supported by a 2-in. angle iron riveted on the inside, 20 in. above the lowest point of the pyramid forms the false bottom. These boxes are supported on timbers high enough above the cement floor to permit a man to stand up to work about them. The solution enters the first box through a false compartment, flows under the screen, then up through the zinc and over into the next compartment; 28 in. is the distance from the screen to the overflow of each compartment. A 12 by 12 in. wooden launder beneath each row of boxes carries the discharge to a launder of the same dimensions, which discharges into a steel vat with capacity for holding all of the solution from one row of zinc-boxes during a clean-up. It is connected to a 2-in. centrifugal pump which lifts the contents 30 ft. to a lead-lined tank. A hood having a 12 by 12-in. opening in the centre for the escaping fumes during a clean-up is built over the tank. Twelve sets of zinc-boxes are in use; each compartment is packed with 200 lb. of zinc shavings previously dipped in a 2% acetate of lead solution. Strong solution having 0.6 lb. cyanide per ton and a protective alkalinity 0.5 to 1.0 lb. flows through six rows of boxes, and a weak solution—the strength of cyanide per ton of solution being 0.3 to 0.4 lb. and protective alkalinity, neutral to 0.2 lb.—flows through the other six boxes.

In Central America the high-water mark is difficult to determine in the rivers, owing to the dense growth which covers the valleys between the periods of flood. These usually occur at intervals of 6 or 8 years. Trees more than a foot in diameter will grow up in this period, and the only sure test is to find the limit of the growth of hardwood. The floods carry everything before them, when they occur, and all vegetation is uprooted.

The Suffioni or hot springs of Tuscany emit steam at 110° C, which has never been utilized for power owing to the corrosive substances in the vapor. An attempt is being made to overcome the difficulty and utilize this great natural supply of power for generating electricity.

CENTRAL NEVADA.

Written for the MINING AND SCIENTIFIC PRESS
By A. H. ELFTMAN.

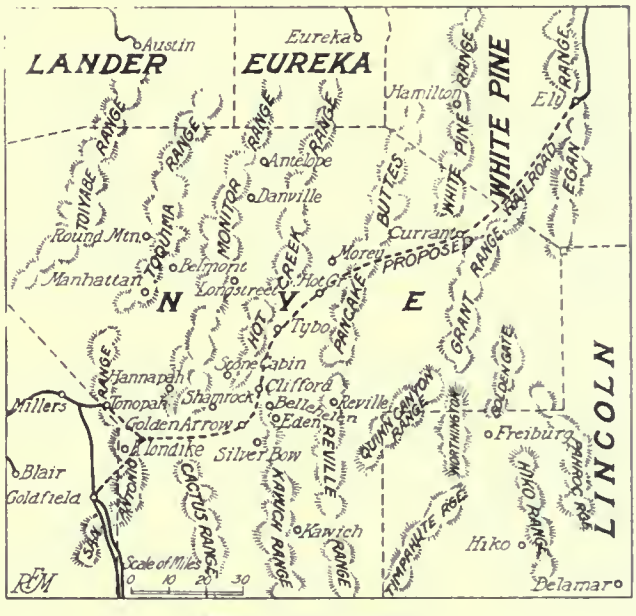
The increased activity in the development of the mineral resources of Nevada, and the projected railroad from Ely to Goldfield and Tonopah, is directing attention toward the camps of central Nevada, the progress of which has hitherto been retarded by the lack of transportation facilities. Desultory exploration in this region has proved the existence of numerous prospects warranting development even under the present adverse conditions. Indeed, several mines have been tested to a depth of several hundred feet, and many other properties show that they would be paying mines if operated under conditions similar to those found in districts favored with railroads.

A glance at the map of Nevada shows that Ely, being the acknowledged smelter centre of the State, has commercial interests that demand a short line of railroad to the southern Nevada camps if a practicable route can be found. The present distance from Goldfield to Ely by railroad is 730 miles, over three separate railroads, necessitating transfers at Mina, Hazen, and Cobre. A railroad direct from Ely to Goldfield would be about 175 miles long, or only one-fourth the present distance. The accompanying map, comprising an area 150 miles square, shows the position of the towns, railroads, and mountain ranges of the central part of the State. This region is traversed by a number of high ranges whose main axis is nearly north and south. Between the Southern Pacific railroad in the north and the Clark railroad in the south there is only one pass that is feasible for a railroad across the central part of the State. This is the Clifford or Warm Springs pass, separating the Kawich range from the Hot Creek range. The whole route is very favorable to the construction of a railroad. Leaving Goldfield at an altitude of 5700 ft. the first 12 miles would drop 400 ft. to the Ralston valley, which is nearly level at an altitude of 5300 ft. for 25 miles to the western slope of the Kawich mountains. The next 30 miles rise to 6300 ft. at the Clifford pass. The following 25 miles drop about 500 ft., and the remaining 80 miles varies from 5500 to 6400 ft. at Ely. The most difficult feature of the road is the outlet across the Egan range at Ely.

The first mining district encountered is that of Kawich, from 50 to 75 miles east of Goldfield. This comprises the camps of Golden Arrow, Silver Bow, Horseshoe, Bellehelen, Clifford, and Eden, situated around the north end of the Kawich mountains. Of these Golden Arrow is the most developed, and from its favorable site is likely to be the distributing centre for the Kawich country. The deepest mine, at Golden Arrow, is down 230 ft., with large veins of good ore. Water was encountered at a vertical depth of 175 ft., thus assuring a sufficient supply for all purposes. Other mines are securing equally favorable results with depth. The camp is now 45 miles distant from Tonopah. Silver Bow is 15 miles southeast of Golden Arrow and 60 miles from Tonopah. There are two mines that can ship ore at a profit at the present distance.

Bellehelen and Clifford, respectively 8 and 15 miles northeast of Golden Arrow, and both 52 miles from Tonopah, have several mines developed to a depth of over 100 ft., exposing large bodies of milling ore. The ores of the Kawich camps are silicious, carrying gold and silver.

The next important mining country is that around Hot Creek, which is 25 miles northward. This comprises the camps of Tybo, Hot Creek, and Morey, all of which were thriving producers twenty years ago, and now have a large tonnage of ore ready for shipment as soon as a railroad is built. The ores are base, carrying copper and lead, with silver and gold. About 50 miles east of Hot Creek is Currant Creek, which will serve as an outfitting point for the



Map of Central Nevada.

development of the numerous prospects in the Grant range, and now wholly neglected. North of Currant is the Duckwater district.

The country from Currant to Ely is being developed from Ely. Several other camps will be tributary to points on the new line. The camps of Longstreet, Danville, and Morey will be nearest to Hot Creek. Reveille, an old producer, now 70 miles from a railroad, will be within 20 miles of the new road. Golden Arrow will have as its tributaries, Shamrock, a promising copper camp in the south end of the Monitor range and eight miles west, and Kawich or Gold Reed, now 75 miles from a railroad, which will be only 30 miles from Golden Arrow.

Central Nevada, from the Kawich range eastward, is well supplied with timber and water, and with improved transportation mining operations can be conducted much cheaper than at Goldfield or Tonopah. The direct benefit derived from this railroad by southern Nevada will be a new opening for its ores, reduced freight rates, and direct connection with what will be virtually an independent transcontinental line, consisting of the Tonopah & Tidewater, Tonopah & Goldfield, Ely & Goldfield railroads, and the Nevada Northern, connecting with the Western Pacific.

SUSPENDED IRON FRAME VANNER.

By Grant B. Shipley.

It will be noticed that this new machine (recently placed on the market by the Allis-Chalmers Co. of Milwaukee) is constructed of iron and steel, excepting the pulp distributor, which is of wood. In the regular vanner, as ordinarily constructed, the frame is supported on each side by rectangular steel bars, spaced an equal distance apart, and the resulting side shake or stroke is in a horizontal plane. In the iron frame suspended vanner, the frame is hung from two rods on each side, which are so arranged that the side shake imparts a peculiar motion to the belt, the longitudinal centre line remaining stationary in its vertical plane while the sides are alternately raised and lowered in their vertical planes, thus causing a panning effect so desirable in the concentration of finely crushed materials. This motion has the effect of not only settling and separating the mineral from the pulp, but it prevents the formation of sand corners, along the sides of the belt, which diminish the capacity of the machine and cause the pulp to slop over onto the working parts. The particular features of this machine are as follows:

The peculiar motion imparted by the side shake.

The adjustable side-shake motion regulated by the eccentrics.

The combined cone pulley belt-tightener and adjustable support.

The adjustable gate on each pipe of the water distributor.

The independent adjustment at the four columns for regulating grade of belt.

The universal drive for worm and worm-wheel on the head roller.

The shaking frame, built entirely of steel.

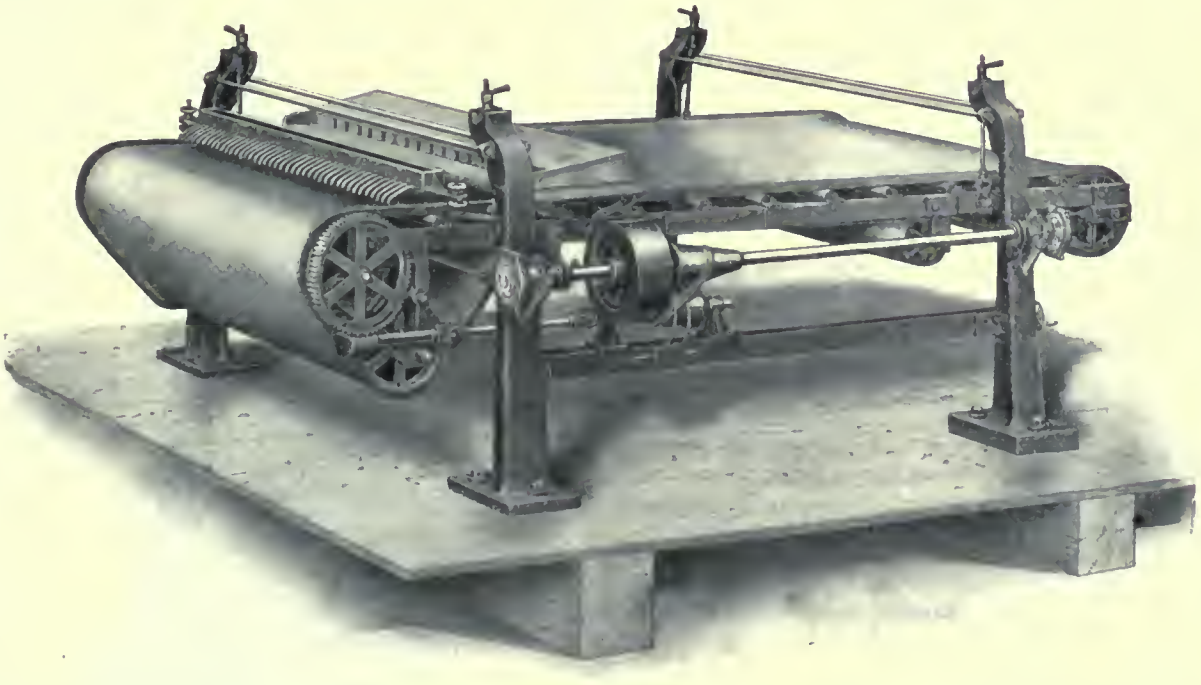
The perfect access to all adjustments and clear space underneath machine.

The driving power is applied through a belt from the overhead counter-shaft to the combined flywheel and pulley, which in turn transmits its energy to the main shaft running parallel to the length of machine, on each end of which there is secured an adjustable eccentric for giving the side shake to the frame. Adjacent to the main pulley, on this shaft, a cone-pulley is located that drives a similar pulley, on the worm-shaft, through a belt. These two cone-pulleys are for the purpose of giving the worm-shaft a wide range of speed, the worm transferring to the worm-wheel the desired speed for driving the head-roll.

In order that there shall be no slippage on the cone driving belt, a practical arrangement is incorporated consisting of a steel frame, adjustably supported on the rear column and guided on the front columns so that it acts as a floating belt-tightener, as well as a support for the worm-shaft and cone-pulley. For varying the speed of this worm-shaft, a sliding forked guide is provided and is controlled by a hand-wheel on the rear end of the floating support.

The travel of the belt depends upon the material treated. If a rich coarse pulp is fed onto the machine, the speed will be slower than if concentrating a lean coarse pulp; and the same thing will be true when handling slime. The incline of the belt also depends upon the character of material treated and will vary from two to six inches in its complete length. When concentrating a fine pulp, containing a large proportion of gangue and only a small portion of mineral, the grade of belt will be small, say about two to three inches, whereas, if the material is coarse and heavy, the grade will be increased. With the adjustment of this machine, the grade of the belt can be regulated quickly and accurately.

Owing to the great variety of ores treated on a machine of this kind, it must be so constructed as to permit of a wide range of adjustment. Adjustable eccentrics for varying the side shaking motion are provided, by which a long or a short stroke can be obtained.



BOOKS RECEIVED.

'Mining, Mineral, and Geological Law.' A treatise on the Law of the United States. By Charles H. Shamel. Published by the Hill Publishing Co. 620 pages. Price $5. For sale by the Mining and Scientific Press. This business-like volume, of standard 6 by 9 in. size, bound in durable buckram, with a leather label, creates a good impression at first sight, and the impression is fully confirmed by a glance at the well illustrated pages. It is a most useful book, prepared by a scholar who is both a lawyer and a scientific man, and written with a generous spirit to other workers in the same field. The contents include an outline of the mining law; the definitions of geology; a sketch of the law of property in minerals; legal definitions of mineral and ore, with citations from celebrated cases; theories of ore formation, with the necessary drawings and references; the extra-lateral right and the interpretation of it; mining laws as applied to the public domain; acquisition of mining rights; scientific definitions of veins; the legal definition and litigation; tunnel and placer rights; and finally an appendix giving the United States mining laws and the Land Office rules and regulations in reference thereto, ending with a bibliography and other useful information. The foregoing will give the reader an idea of the

comprehensive and practical character of the book. It is rarely given to any writer to cover two or three branches of learning without blundering, and as a rule the attempt to be lawyer and geologist concurrently evokes vigorous criticisms from both professions, but in this case we discern no cause for finding fault; we thank the author for honest work well done, resulting in a book as useful as it is interesting, and likely to be of the greatest value to those engaged in mining.

'Engine-Room Chemistry.' By Augustus H. Gill, Associate Professor of Technical Analysis, Massachusetts Institute of Technology. Hill Publishing Co. 198 pages. Price $1. For sale by the MINING AND SCIENTIFIC PRESS. This is a compendium on the subject written for the engineer and engineman so as to enable him to understand the scientific principles underlying the modern instruments used in power plants and to comprehend the principles of combustion and lubrication. The author assumes no greater knowledge of chemistry and physics than can be obtained from elementary books such as the 'Science Primers,' published by the American Book Company.

VACUUM PUMPS FOR DIRTY WATER.

The idea of raising water by the condensation of steam in a chamber and then forcing it up to a still higher level by the direct pressure of steam on the surface of this water in the same chamber, originated with Capt. Thos. Savery, who in 1698 patented his celebrated 'fire engine.' Properly speaking, his device was not an engine but a sort of pump, a forerunner of the present Emerson steam-pump. In operating Thos. Savery's engine one cylinder was filled with steam, the steam valve was closed by the operator and a spray of water was then injected into the steam. The continual services of a man were needed to operate the steam valve and an almost continuous stream of water was delivered. A great sale was built up for this pump until Newcomen's atmospheric engine displaced it and piston pumps began to come into the field. The displacing of Savery's pump was largely due to the fact that the expansive power of the steam was wasted, and the steam consumption was hence enormous. No progress was made in vacuum steam pumps for nearly 200 years, when in 1872 and 1881 Charles Hall patented the pulsometer.

A saving of at least 25% in the amount of fuel, one of the main advantages of the Emerson pump, is the result of early steam cut-off, which is made possible by the design of the rotary slide valve steam ports.

In general, as shown in the sectional cut, the Emerson pump consists of two long cigar-shaped cylinders or receiving tanks, each connected at the bottom through upward opening valves with the suction pipe; and also connected, again with upward opening valves, with the discharge pipe, thus having but four valves in all for the average standard pump.

In the Emerson pump the steam is used twice. First it presses directly down on the surface of the water in the chamber and forces it out through the discharge pipe. Second, this same steam is itself then suddenly condensed, creating a vacuum which refills that chamber with a new charge of water. Where two cylinders are used as shown in the picture one of them (which we will call cylinder No. 1) with full boiler pressure acting on the top of the water, is discharging; while at the same time the other cylinder (which we will call No. 2) has just created an almost perfect vacuum and is sucking in the water. Filling the vacuum requires less than two seconds, and after an interval of only a fraction of a second the next inrush of steam into that chamber empties it in about two more seconds. After an interval of but a small fraction of a second, the water having been expelled and cylinder No. 1 full of live steam, a jet of cold water, as shown in the picture, is forced from cylinder No. 2 into this steam, condensing it and creating an almost perfect vacuum, thus completing the cycle for cylinder No. 1. This cycle can be summarized as follows:

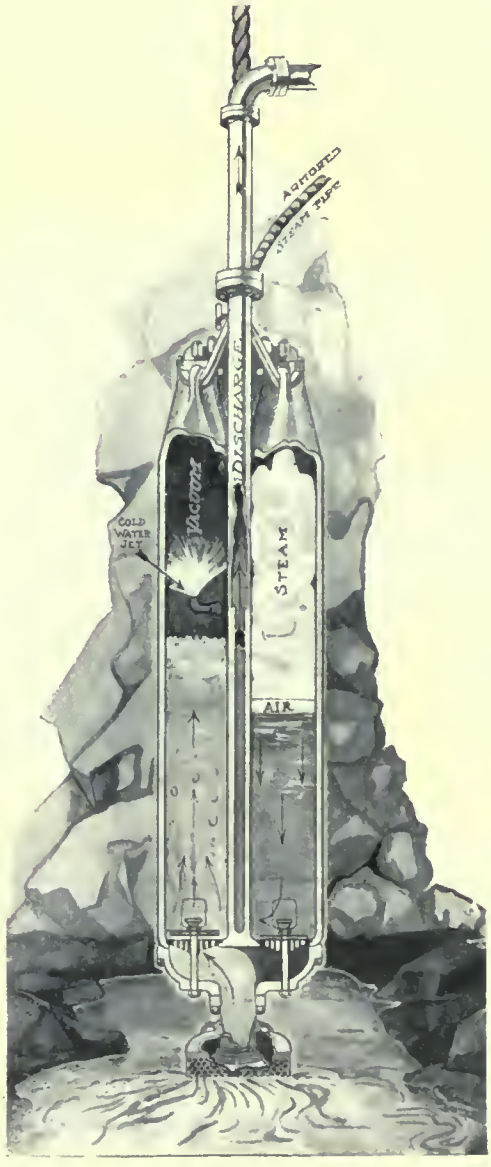
A. Steam admitted to cylinder No. 1 forces out liquid.

B. Same steam condensed by jet of cold water from cylinder No. 2 creates vacuum.

C. Vacuum thus formed refills No. 1 with water from the suction pipe, regardless of possible inrushing air, until the vacuum is relieved.

These items take place alternately in the two chambers. That is, comparing this pump with the human heart, one cylinder is acting as an auricle while the other is acting as a ventricle.

As all users of pumps realize, the wear and tear created by sand, grit, loam, or any foreign matter, is a very serious item. By studying the pictures herewith it will be noticed that the liquid being pumped never comes in contact with anything which moves, except the four round rubber valves, two in the suction and two in the discharge pipes. Thus



the gritty material can be handled without the necessity of frequent repairs because the Emerson pump employs no plungers, pistons, piston rods, glands, stuffing boxes, nor any other moving parts to come in contact with the water being pumped.

The weight per given capacity is considerably lower than that of any other pump on the market. A pump with a capacity of 1200 g.p.m. against a 25-ft. head weighs only 2700 lb. It should be remembered, too, that there is no engine to be bought in order to furnish power to the Emerson pump, since the steam from the boiler is made to act direct, both in expelling the water and, by means of a vacuum, in sucking in the supply from the sump. Since this pump is self-contained and operates entirely on the principle of steam expansion against a column of liquid, it follows that its weight is less than the weight of other pumps plus the weight of the engine necessary to drive them.

Editorial.

GENERAL FINANCIAL conditions are improving rapidly. Manufacturing establishments are re-opening, the metal markets are more cheerful, and freight traffic is increasing. The violence of liquidation has spent its force and the normal progress of industry is being resumed. As soon as the result of the presidential election can be discounted, a complete recovery will be hastened.

FROM NEW YORK we learn that there is a marked revival of financial interest in mining, notably in the enterprises under way at Guanajuato. This is due to recent discoveries of rich ore in the San Nicolas El Monte, the Penguico, and the San Cayetano mines. We hope these finds will prove important, for the men that have devoted their energies and their skill to the development of the old mines of Guanajuato deserve success. *Buena suerte mis amigos.*

LAST YEAR Mr. W. A. Caldecott, consulting metallurgist to the Consolidated Gold Fields of South Africa, came to this country and to Mexico with a view to seeing new methods of cyanidation. On his return he told his technical friends at Johannesburg what he had seen. The observations of so fair and experienced a critic are of interest to cyaniders everywhere, so we have abstracted the larger part of the paper that Mr. Caldecott read before the Chemical, Metallurgical & Mining Society of South Africa.

THE *Morning Howl* and the *Evening Scream*, the leading papers of San Francisco, continue to publish big advertisements of the Industrial Investment Co., in which that Arizona corporation offers stock in prospects at Rawhide, Nevada, to the people of California. "You can buy stock at 5 cents per share today and tomorrow," but "on Sunday next the price will go to 10 cents." Hurry up. Among the powerful arguments for making such a purchase is the fact that the *Daily Mining Record*, of Denver, "the recognized mining authority," speaks handsomely concerning the Investment Co.'s holdings. The president of the latter is advertised as "former western manager of the *Daily Mining Record*," hence the interchange of compliments between the advertisements of the one and the columns of the other. As a matter of information it may be added that the Denver paper mentioned is not in the least authoritative on any subject, and is chiefly remarkable as an incubator of wild-cats.

INFORMATION not intended for publication is usually more interesting than that which is prepared for publicity. On another page we reproduce

a letter written by one mine-operator to another in regard to Rawhide, Nevada. This general account of impressions gathered during a visit to the new mining camp is published by permission of both writer and recipient, but their names are omitted, for obvious reasons. To us the letter is interesting not only as indicating the unwillingness to form a final opinion but also the earnest effort to interpret the occurrence of ore in the light of current geological knowledge. It illustrates the tremendous advance made by the science of geology in winning the respect of hard-headed men and their belief that it aids them in understanding the conditions that make mines. Note also how disinclined the operator —an experienced man—is to condemn the district, although he sees that it is being over-boomed and is obviously being used as an excuse for all sorts of nefarious schemes. The record of Cripple Creek, Kalgoorlie, Goldfield, and other gold-mining districts that have won fame during the last twenty years has been a warning against hasty opinions. Even spurious promotion cannot kill a rich district, although it may hinder its development.

Mining and Metallurgical Societies.—III.

IN the two preceding articles we have discussed the character, function, and performance of the existing organizations comparable to the Mining and Metallurgical Association, which it is the intention of some of our friends to form forthwith. Having refreshed our memories in regard to the work done by the Institute, the Institution, and the Mining Congress, we are in a better position to discuss the prospects of the new Association. And what may be the purpose of it? This is answered by making excerpts from the circular letters received by many of our readers. It is stated that:

1. The Association is intended to be one in which membership will have some meaning as to professional standing. To accomplish this, membership is to be restricted to those credited with technical attainments and honorable achievements.

2. It is not the intention to build up a society that shall be a rival of either the Institute or the Mining Congress. The diffusion of technical knowledge is the principal object of the Institute, and the improvement of mining conditions is the end sought by the Mining Congress; the objects of the first are educational and technical; of the second, economic and legislative. The purpose of the Association is technical and ethical.

3. As it is not desired to weaken the Institute by lessening its membership or diminishing the interest in its continued prosperity, it has been suggested that membership in the Institute be a condition precedent to becoming a member of the Association.

Referring to the first paragraph, it has been proved by the experience of the other societies that absence of restriction results in a nondescript membership, impotent in public or professional matters, because deficient in solidarity; while, on the contrary, a restriction, if based on training and performance, will produce such fellowship as is stimulating to good work, that is, work in the direction for which the society is organized. One of the most effective precautions is to require a large number of sponsors, all of whom have personal knowledge of the candidate. Members should have it impressed upon them that they are on their honor not to sign applications irresponsibly.

The second paragraph states the case plainly, but, on the very face of it, there is need of a correction. The repetition of 'technical' in summarizing the objects of the three organizations, suggests that there is a chance of duplication of work and therefore of rivalry between the Institute and the Association. It is true that the Association will be composed of technical men especially qualified to discuss technical subjects, and therefore it seems natural that technical papers should be read at the meetings of its members, but if this is done, then the declaration as to unwillingness to injure the Institute, as expressed in paragraph No. 3, is without sincerity, for it is obvious that the Association will attract the reading of many of the best papers, which otherwise would be sent to the Institute for publication. As we have the most thorough belief in the sincerity of purpose prompting the organizers of this new Association, we urge them to excise the word 'technical' from their program. Any attempt to include the reading (and consequent publication) of technical papers will be a trespass on the good work now being performed by the Institute under Dr. Raymond; it will lead to rivalry, bitterness, and all sorts of misunderstandings. And it is not necessary for the Association to perform this function; it is being well done already. Besides, there is other territory not already pre-empted. It is the ethical, social, and professional sides of the mining engineer's, metallurgist's, and geologist's life that need buttressing and stimulating; it is the relation of the engineer not to nature but to his fellow man that requires elucidation and elevation. There is plenty of scope. The Association should not hesitate to invade the ground traversed by the American Mining Congress, for neither on the score of representation nor performance has the Congress won any prescriptive rights. Similarly, most of the State organizations, such as our California Miners Association, have failed to be representative and have been unable to develop any such public spirit as would have given them the motive power to be serviceable in a large way to the community. Therefore the new Association is warranted in concerning itself with such industrial and legislative problems as interest a mining engineer imbued with civic spirit. The reform of the mining law, fraud in mining, the engineer's relation thereto, smelter rates, national administration of mining affairs, the work of the Geological Survey, the labor problem—these are a few of the topics that will be perennially interesting and upon which the Association can give an authoritative opinion. In short, let the Association undertake to do what the Congress never could do; let it avoid doing what the Institute does so well; let it tackle the problems that the Institute has chosen to disregard. Above everything, the Association should

devote itself to improving the relations between professional men engaged in mining and metallurgy, and the relations of those men to the public. Surely that in itself is enough to constitute a bond of fellowship. There will be discussions, and those discussions can be printed, as are the proceedings of other societies, and in the end we shall have a body of literature quite as interesting and as useful as the description of a gold mine or the details of a cyanide plant. There is no reason to fear a lack of subjects, for when national and industrial problems relating to mining have been satisfactorily settled—in the Greek kalends—there remain ethical and professional questions of great interest and subtlety, and as numerous as the many-sided human nature of which we are all composed. We may suggest: 'Standardization of professional practice,' 'A rudimentary code,' 'Our relations to the public,' 'Amenities between the consulting engineer and the manager,' 'Duty of the engineer to his directors,' 'Should engineers speculate,' 'Is it advisable to own shares in the mine you are managing.' 'Is it right to resign when the ore becomes refractory,' 'When does loyalty end, and self-interest begin,' 'Why directors are incapable,' 'Why shareholders are a nuisance,' and so forth. Gentlemen, you have a new world to conquer, let the Institute and the Institution, and even the Mining Congress, elucidate the operation of machinery and the working of mines, you have the varied, variegated, and vast domain of human conduct in its relation to the mining industry. Is not that enough?

Next, as to details: Would it not be well to have an understanding or unwritten law among members that membership be not used as a diploma of efficiency, nor appear on letter-heads, nor be used as a luminous tail to a signature—in short, that inclusion within the Association be treated as we treat membership in a club. Has not this infraction of good taste brought scandal upon many scientific societies and technical institutes? Is it not an abuse of fellowship? Further, even if the endorsements required of a candidate to membership be limited to the usual number of three, would it not be advisable to insist not only upon personal acquaintance but also some definite knowledge concerning the antecedents of the candidate. If a right start is made in this regard, it will be easy to establish a precedent, but if undue anxiety is shown for the enrollment of a large number of members, then there will be an inevitable laxity, ending in giving the Association a heterogeneous composition fatal to its effectiveness. Other societies furnish plenty of warnings. Mere numbers do not mean much. An organization shows stronger vitality and can do better work if out of 500 members, 100 or 125 foregather, than one having 4000 members, of whom only 50 to 100 come together. The social side of this Association ought to be a distinct feature of it. Man is a sociable animal rather than a gregarious beast, and there is no doubt that engineers, especially the nomads engaged in mining, love to compare notes and exchange experiences in an informal fashion, not necessarily at costly banquets, but in a simpler way, when conversation supersedes speeches, and plain food accompanies well-seasoned talk. If meetings are held at various centres, according to the distribution of membership, even if only a handful assemble, the occasion can be made useful in furthering the objects of the Association. The desire to be present will be strengthened by the expectation of contact with men of kindred spirit, fellows full of interesting information, and members glad to emphasize the essentials of intelligent fellowship. The important meetings are likely to be held in one or other of the cities on the Atlantic seaboard, but it might be arranged that on the same day those unable to attend would foregather in their own habitat or, better still, agree to do so on the arrival of the report of the Association's general meeting, with a view to discussing the subjects brought forward on that occasion. In this way the discussion of professional matters could be made general, and every member would have a chance to exchange ideas with some of his fellow members. The post and the telegraph, not to mention the wireless sympathy of men engaged in kindred pursuits, render it easy to maintain inter-communication, always provided that the membership is so selected as to constitute a fraternity. There exists the material for such an Association and there is the will to give it motive power, for already over a hundred men have agreed to become charter members. Among them is the present writer, for not otherwise would it have been permissible for him to be so frank in his criticism and recommendations. We hope the Association will become a power for good in improving the relations between professional men, and between them and the public. If it does that, it will have performed a great service to mining and metallurgy.

Postal Regulations.

BY ORDER OF the Post-Office Department, it has been ruled that expired subscriptions are no subscriptions at all, and unless renewed within a certain specified period the copies mailed on account thereof shall not be accepted at the second-class postage rate of one cent per pound, but may be mailed at the transient second-class rate of one cent for each four ounces or a fraction thereof, prepaid by stamps. It is needless to say that publishers cannot afford to pay the transient rate; in the case of the MINING AND SCIENTIFIC PRESS the postage would be $1.04 per annum. This ruling has been generally endorsed by reputable papers, for it infringes no rights and is calculated to stop abuses that have prostituted journalistic enterprise to the use of the worst forms of feline finance. Too many publications masquerading as technical or financial journals are merely circulars for the advertisement of swindles, they are mediums of misinformation of the rankest kind, and are not entitled to the postal facilities meant to further legitimate enterprise. It is a fact that newspapers and periodicals enjoying the second-class mailing privilege constitute 67 per cent of the matter carried in the mails, but yield only 4 per cent of the total revenue. No wonder the Post-Office authorities have called a halt. They will be supported by all reputable publishers.

Personal.

M. L. Requa is at Ely.

Horace V. Winchell is at Goldfield.

Thos. H. Leggett is at Globe, Arizona.

Waldemar Lindgren is in San Francisco.

Edgar Rickard has returned from New York.

Gelasio Caetani is at New York, on his way to Rome.

W. Murdoch Wiley is at the Engineers' Club, New York.

A. Chester Beatty is expected in San Francisco next week.

H. J. Baron has resigned as associate editor of *Mining Science.*

Wilbur E. Sanders has moved from Los Angeles to Nevada City.

Wilton E. Darrow, of Sutter Creek, is in San Francisco for a few days.

Fred A. Gowing has returned from Rawhide and Golden Circle, Nevada.

John C. Montgomery was here. He is now at Rawhide, accompanied by Henry Krumb.

H. P. Gordon is now foreman of the San Domingo hydraulic mine, near Angels, California.

C. H. Munro has returned from Colombia, where he has been prospecting dredging ground.

E. W. King, of Bozeman, Montana, is heavily interested in the new prospects at Rawhide, Nevada.

C. B. Lakenan is general manager for the Steptoe Valley Smelting & Mining Co., at Ely, Nevada.

W. E. Thorne, of Auburn, has been doing professional work in Tehama and Shasta counties, California.

Foster Hewett, of the Pittsburgh Testing Laboratory, is in San Francisco, on his way from Grass Valley to Pittsburg.

J. H. Hartley and his brother, Z. B. Hartley, have formed a partnership as mining engineers, at San José, Costa Rica.

Edgar A. Collins, superintendent for the Montana-Tonopah Co., goes to England in April, to be absent on a three months' holiday.

W. A. Connelly, superintendent of the Constancia mines, in Nicaragua, sailed from New Orleans on March 14, on his return to Nicaragua.

Frank M. Estes, Jr., formerly mine foreman of the Esperanza, has returned from a trip to Europe and is now in the Joplin district of Missouri.

F. B. Weeks, who has been connected with the U. S. Geological Survey for the past 18 years, has recently resigned. His address for two or three months, while completing certain reports for the Survey, will be 1201 Euclid St., Washington, D. C.

Rensselaer H. Toll, who has been engaged for the past ten years in gold-mining and milling operations in the Southwest and Mexico, during which time he has had charge of several important enterprises in the La Plata and Cripple Creek districts, has opened an office as consulting engineer at 522 Mining Exchange, Denver.

Cortlandt E. Palmer, connected with the Guggenheims for the past five years in charge of mine and mill construction and operating in the United States and Mexico, has modified his arrangements with these interests. Mr. Palmer will act in future in an advisory capacity to the American Smelters Securities Co., without field-work, and will continue in charge of operations for the Esperanza Mining Co. as vice-president and consulting engineer. Additional to the above, Mr. Palmer has accepted the appointment of general manager for the Guanajuato Development Co., operating the Peregrina and Pinguico mines and mills and a number of allied enterprises at Guanajuato, Mexico, his headquarters being at 40 Wall St., New York.

General Mining News.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—A meeting of the directors of the Calumet & Arizona Mining Co. was held recently at the Copper Queen hotel in Bisbee. It was decided to allow the option on the Leadville group near Gleeson, Ariz., to expire. This is one of four properties that the Calumet & Arizona has held by option and upon which the company has been doing development work for the past eight months. A final payment of approximately $300,000 was due on the day of the meeting. No action was taken on the dividend.

Bisbee, March 20.

CALIFORNIA.

BUTTE COUNTY.

At the Big Butte drift placer mine the pay gravel has been reached in a raise. The mine is on the west side of Big Butte creek, 18 miles from Chico.——The new power plant of the P. B. Steifer Mining Co., being erected near Magalia, is nearly finished and will start up about the beginning of April. The plant will develop 360 hp., which will be used for pumping and hoisting.

CALAVERAS COUNTY.

Rich placer ground has been found, covered by a slide in Buckeye gulch by McSorley. The gold is exceptionally coarse. The extent of the deposit is not yet known.

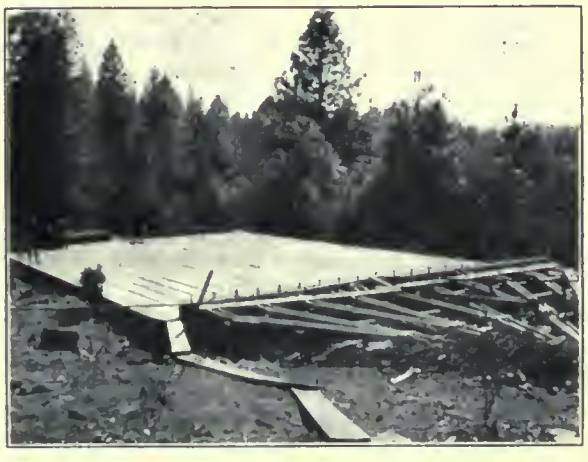
NEVADA COUNTY.

(Special Correspondence).—A movement of considerable importance to the mining industry is taking place in this district. It is a plan providing for running a long tunnel to drain the mines of Nevada City and Grass Valley. An attempt was made a number of years ago to run the tunnel, but it proved abortive on account of poor management and lack of funds. This tunnel is to be started on the South Yuba river, at an elevation of 1150 ft. above sea level (somewhat lower than the first one), and running on the quartz lodes which follow the contact between the granodiorite massif and the porphyrites and metamorphic schists, it will reach the Champion mines in a distance of 15,000 ft. After traversing the Champion veins for a distance of two miles, it will leave the contact and, turning southward, will cut in turn the rich and productive veins of Grass Valley.——From the district tributary to this adit a steady production has been maintained for almost 60 years. At present at least $250,000 per year is spent on pumping. A small percentage of this amount, it is stated, would pay the interest on the cost of the adit, and the remainder could be used in the further development of the mines. Considering the relatively flat dip of these veins, it is apparent that an adit which drains them at a vertical depth of from 1100 to 1800 ft. will be of great value in their further development. This adit will strike the Champion shaft at the 2200 level, the Empire about the 2500, and the North Star at the 3400 level. These mines and the Idaho-Maryland are the only ones that are at present as deep as the projected drainage tunnel, and there are over 30 shafts of considerable depth along that line.

It is estimated that the cost of the entire tunnel will be about $1,000,000, but it ought to be paying its own way long before it is completed. The leading mining and engineering people of the district are not doubtful as to the feasibility of the scheme and the advantages that are bound to accrue from it. Besides the drainage work, the tunnel company will have a large field in the way of handling ore, which will be done with electric haulage. Water and electric power are both easily available at the portal.

Nevada City, March 23.

A discovery of rich ore has been made in the winze in the 300-ft. level north of the Kenosha shaft. The streak is 8 to 10 in. wide and carries free gold. The ore is a white quartz, with sulphides and free gold. A cross-cut will now be run on the 400-ft. level to cut this vein. The mine is situated on Deadman's Flat.——Work in the Belle Union mine has been delayed by caving ground. It is expected that the vein will be cut within a few days.——Rich gravel has been struck in the Posey Canyon gravel mine. An adit has been driven during the last three years, and a 16-ft. raise encountered the old channel. Drifts and cross-cuts will now be driven to determine the extent of the pay gravel. H. C. Zapf is president of the company.——The Jenny Lind company is driving an adit to reach the same channel.——At the Bessie mine preparations are being made to erect a stamp-mill. The development work has been carried to a depth of 200 ft. and good hoisting and pumping machinery is installed. The mine is situated in Brown's valley.——A hoist is being erected at the Champion mine to sink a winze from the 800-ft. level. This will be sunk 300 ft. and connected with the Wyoming shaft.——Considerable interest is centred on a discovery made about 13 miles below Nevada City, where a large lode, containing some silver and lead and traces of gold, has been uncovered and traced for a great distance. A. D. Foote, superintendent of the North Star mines, is said to have bonded 360 acres of the best land.——The company which recently secured a bond on the Republic mine near Graniteville, has started work there. This week several men were put to work to extend the lower adit. The work of development will be carried on steadily, and through this adit a large amount of new ground can be opened up. As soon as the snow disappears and the roads are open the machinery for the additional five stamps will be hauled to the Republic and installed. The company intends to do much work there this year, and thoroughly open up the property.



Slime Plant, Empire Mine, Grass Valley.

(Special Correspondence).—A rich shoot of ore has been encountered at a depth of 300 ft. in a winze at the Kenosha. The quartz carries free gold, and was found north of the shaft. Several good specimens were extracted. The shaft is going down rapidly. A drift has been started from the 400 level to cut the vein.——It is announced that work on an enlarged scale will shortly start at the West Point mine. A small crew of men are at present engaged sinking a prospect shaft on a vein on the west side of the mine.——A good lode of milling ore is being developed at the Gold Mound. Sinking continues steadily, a small force of men carrying on the work. Howard P. Dennis is superintendent.——The shaft at the Normandie mine is going down. Several promising shoots of ore have been encountered.——A good shoot of ore has been struck in the Sultana group. Extensive development work is going on.——Small quantities of rich ore have been encountered in a winze at the Pennsylvania mine. It is expected that the main pay-shoot will soon be tapped.——Active operations have commenced on property adjoining the Mason ranch, recently bonded by A. D. Foote and associates. A 25-ft. prospect shaft is being sunk and a cross-cut will be driven from the bottom of the shaft. A. Hall has been placed in charge of the work. If the ore proves sufficiently rich, shipments will be made through New England mills to reduction plants.——The Native Son mine in the Blue Tent district has been bonded to J. H. Bishop. Several

men are at work clearing out the old tunnels, preparatory to the driving of a cross-cut to intersect several small veins exposed near the surface.——Two adits, 180 and 80 ft. long, respectively, and a 150-ft. cross-cut tunnel have opened up a large body of ore at the Golden State group near Chicago Park. Several winzes disclose fair-grade ore. A small force of men are driving the cross-cut to intersect the orebody.——It is rumored that Colorado people are negotiating for the purchase of the Mountain Maid mine. ——Several men have been added to the working force at the Republic mine, and the lower tunnel is being rapidly pushed. The company is arranging for carrying on extensive development activities.——Arrangements are being completed at the Champion mine to sink a winze from the 800 level to a depth of 300 ft. Connection will be eventually made with the Wyoming shaft. George Mainhart is superintendent. A hoist has been installed to facilitate the work.

Grass Valley, March 23.

PLUMAS COUNTY.

H. H. Yard, who has operated extensively in Government lands in Butte and Plumas counties, seeking to obtain public domain, has lost possession of about 265,000 acres along the Feather river. The Land Office at Susanville has rendered a decision and report setting forth that in more than ninety claims there is no evidence of mineral. The lands taken by Yard, largely, as the Land Office claims, through dummy locators, under the plea that they are mineral in character, cannot be held by him, and revert to the Government as timber lands. The assessment work which he claimed had been done, partly by prospectors, before the advent of Yard, consists of roads and telephone lines, which do not constitute lawful assessment work. The decision further states that the prospects made by Yard, as well as those made by the Government, prove that there is no placer gold in the claims which would justify the claim that they are of mineral character.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The holdings of the Red Oak M. & M. Co., situated on Democrat Mtn., have been sold to C. H. Porier, representing a syndicate of St. Louis (Mo.) capitalists. It is reported that a cash bonus of $25,000 was paid, and that the balance of $125,000 will run one year. Work has already been started, and a raise is to be carried from the Scepter adit to connect with the Sunburst adit. This raise will be 370 ft. high, and when completed will permit of the extraction of the ore found in the Sunburst workings at a greatly reduced cost. An aerial tramway will be run from the portal of the Scepter adit, the terminus to be at the site of the Red Oak mill which was destroyed by fire a few years ago.——The Riley lease on the Grant level of the Sunburst continues to improve, and from a shipment of a car-load of second-class ore returns of 225 oz. silver per ton and 12% lead resulted. A new streak has just been uncovered in the stope, which is up 30 ft., and a heavier tonnage is now being mined.——Within 30 days the raise being carried on the Seven-Thirty vein to cut the old workings, and at the same time draining them, will have been completed. This undertaking will result in opening a block of virgin ground that is 1½ miles in length by 150 ft. in height. Owen Rice is general manager.——The adit being run on the Shively to intercept the 500-ft. level of the shaft workings is nearing the objective, and B. J. Martelon, the manager, states that within the next 40 days the objective will be reached. At that time several miles of old workings will be drained, permitting the extraction of the large bodies of low and medium grade ore which are known to exist.——The machinery of the Mendota mill was started up this week, after a temporary close-down of four months. In the meantime a number of improvements were made about the premises. This plant is being fed upon dump matter and ores left in the old stopes above the Victoria adit, and it is estimated that there is enough ore available to run 10 years.——Development will be actively prosecuted on the Dorlc adit holdings, situated on Saxon Mtn. This property has been secured by the Magnet M. & T. Co., operating under a lease. A large tonnage of ore is being broken and shipments have been started to the local sampler. The ore is worth $100 per ton in gold, silver, lead, and copper. C. E. Carpenter is directing the work.——The Raymond adit on Griffith Mtn. is being rapidly advanced. Since cutting the Paris vein, driving has been in progress, a streak of heavy lead ore 8 to 12 in. wide being followed, assaying $16 per ton.——Butts & Co., leasing on the Aastor, have broken into a new streak of high-grade ore. In carrying the raise a body of smelting ore has been encountered that measures from 8 to 10 in. wide.——The discovery made on the Sporting Times mine a few weeks ago is proving up to expectations. The streak has gained in size from 6 to 10 in. The first mill-run produced $84.70 per ton. This property is owned and operated by A. H. Colburn.——A night shift has been put on at the Capital mill.——Hall & Co., leasing on the sixth level of the Bellevue-Hudson, are breaking a steady tonnage of high-grade ore. Stoping is in progress upon a body of ore from 1 to 5 ft. wide. The stuff is being milled in two classes, and assays 174 and 45 oz. silver per ton. The discovery was made in cross-cutting to catch the hanging wall, which was never explored by the old workings.——At the electric plant of the Two American Sisters M. M. P. & E. Co., a 500-hp. steam engine is to be installed, which is to be used as an auxiliary plant. In addition to this, wires are to be run into Georgetown for the furnishing of light and power. At the mine the working force has been increased. J. J. White serves as general manager to this company.——F. A. Maxwell, lessee of the Colorado Central, is maintaining regular shipments of high-grade silver ore from the sixth level. The streak measures from 18 in. to 2 ft. wide, the ground having been opened for 75 ft. One wagon-load of this ore shipped last week brought $1824 net.——The Tol Reynolds on Alpine Mtn. is again undergoing development. A wagon-road recently constructed will result in the product being marketed at a greatly reduced cost.

Georgetown, March 21.

SAN JUAN COUNTY.

Nearly 5300 tons of ore have been shipped from the Silverton district during February. The shipments of concentrates aggregated 5225 tons. The Gold King shipped 2300, Silver Lake 1925, Iowa 725, Sunnyside 175, Old Hundred 100 tons. Fifty tons of crude ore were also shipped. ——The Champion adit will be driven the next 300 ft. by a contract which will be let shortly. The adit is already 700 ft. long, and it should cut the Champion vein at 1700 ft. from the portal and 1100 ft. below the outcrop. Work will soon be resumed by the Green Mountain M. & M. Co. Considerable ore is blocked out, and a satisfactory output for the summer season is expected.

TELLER COUNTY.

The Maud S. Leasing Co., operating on the Red Bird of the National Mining Co.'s ground on the west slope of Gold hill, are driving on a strong vein on the third level, about 150 ft. northwest of the shaft. The vein lies in the phonolite and shows good ore. The vein is increasing in strength as work progresses, and the company hopes to open up a big body of shipping grade ore. A 30-ton shipment was made recently by Powers & Anderson, sub-leasing on block 191 of the Stratton, and the returns showed $32 per ton. The ore was taken out above the 50-ft. level, where a good vein has been exposed. This block has recently been sub-let by Dr. Driscoll and associates, and two cross-cuts are being driven by the new operators.——The contract for sinking the shaft on the Friday claim on Tenderfoot hill a distance of 50 ft. has been completed, and Philip Schuch, the manager, will prosecute the work hereafter on company account. The shaft is down now 125 ft., but it is the intention of the company to sink another 50 ft., when considerable lateral work will be done. No ore is being broken at the present time. The Abe Lincoln mine in Poverty gulch is developing better than it has been at any time since the fire that destroyed the shaft-house on the night of Jan. 1. Five machines are at work

breaking ore of good grade from the fourth, fifth, sixth, and seventh, and two machines are engaged in driving cross-cuts southwest on the 700-ft. level. A good vein of ore showing sylvanite has been encountered in a winze sunk from the 7th level to a depth of 100 ft., but at that point water has handicapped operations. A new spray washer with a capacity of 100 tons daily has recently been installed, and all of the coarse rock is being run through. The slimes, which have heretofore been wasted, have added considerably to the gold output of the property. An elevating tram has also been completed, which lifts the waste from the washer to a point about 40 ft. above the old dump level, which obviates the difficulty before experienced in obtaining dump-room. All of the four sets of lessees on the property are reported as being in ore of good grade, and the mine is producing a car of smelting grade ore a day.

Two important discoveries have been made in the deeper workings of the Lee shaft in the past few days. At the 800-ft. level the No. 4 vein has been entered by cross-cut and from 6 to 8 ft. of ore exposed, returning 4 to 6 oz. gold per ton. This vein was first cut at the 1100-ft. level and in succession in the 10th and 9th levels. A cross-cut will be carried from each succeeding level, and from present indications it will extend upward to the surface, as little work has been prosecuted in this direction in the upper levels. The second and more important find was made at the 900-ft. level. At this depth a vein new to the property and lying parallel to the No. 4 has been encountered. The new vein is fully 4 ft. wide, and at a conservative estimate will ship at 2 oz. gold per ton.——The production from the properties of the Work Mining & Milling Co. situated on Raven and Gold hills, during the month of February amounted to 354 tons, of a gross value of $18,460. The net returns, after the deduction of freight, haulage, and treatment charges, was $15,322, and the royalty paid the Work company's treasurer $5587.——Nine cars of ore shipped before the close of the month and on the way to the valley mills or smelters, are not included in the above. The average value of the ore marketed was $52.48 per ton.

IDAHO.

IDAHO COUNTY.

An important find of high-grade galena is reported on the Amy group of claims in the Pine Creek district.—— The contract to drive a 2800-ft. adit on the Reindeer property has been begun. The contract price is $10 per foot.—— The adit being driven by the Victor Mining Co. on its property in Shields gulch in the Evolution mining district is in 450 ft., and a vein 2 ft. wide has been found.——The North American M. & M. Co. has commenced suit against the Big Creek Mining Co. to clear title to its mining claims in the Yreka mining district. The dispute has arisen over the surveys of the claims.

SHOSHONE COUNTY.

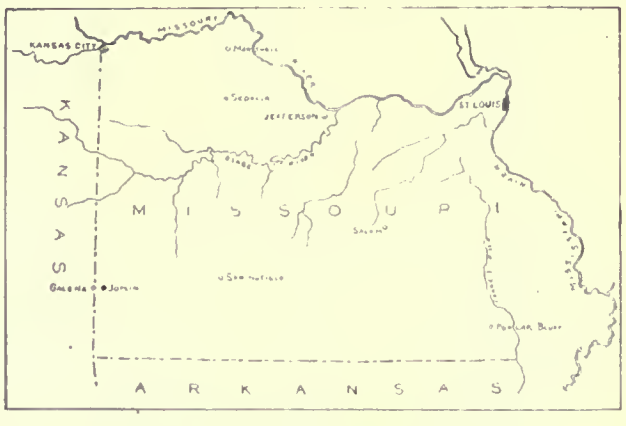
(Special Correspondence).—The Black Bear Fraction Mining Co. has resumed development, after a cessation of four weeks. An adit will now be driven on the 1400-ft. level, working three shifts. This property is considered one of the best prospects in the district near Burke. The ore-shoot has been exposed 250 ft. in the upper workings, and a large working adit from the railroad near the town of Black Bear has been driven into the hill a distance of 2455 ft., and has cut the vein of the Frisco-Morning ore zone. At present the face of the tunnel is about 150 ft. west of the upper adit, and drifting will now turn east to strike the orebody. Peter Bernier, president of the company, will take charge of operations

Burke, March 21.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The unsatisfactory price of zinc concentrates during the past six weeks has caused the operators in the 'sheet-ore' camps of Webb City, Carterville, and Prosperity to allow a large surplus of ore to accumulate in the bins. The surplus is being constantly augmented by the additional mills that have started up in those camps. So great has this surplus become that the operators are again counseling the shut-down of the mills. In Prosperity camp the American Z. L. & S. Co., the largest producers in the camp, refuse to re-open the mines until the price of ore reaches at least a $40 base for 60% zinc. This company produces from 250 to 500 tons of zinc ore and from 50 to 100 tons of lead ore per week. In the Joplin camp the mills upon the Marion B. tract have closed down indefinitely. These mines are bonanza producers, and are among the heaviest shippers in the entire district. ——At no period in the history of the district has there been so much prospecting as during the past three months. The large companies that shut down the mills turned their attention to prospecting the ground they were working, while the men thrown out of work took up leases in the shallow ore camps and have prospected and extended the limits of these deposits. Among the new tracts thus developed was that of Elliot & Zimmermon, south of Webb City, where a drilling campaign was undertaken that resulted in the discovery of a body of sheet ore underlying a large part of 160 acres. Shafts have been sunk on three of the ten-acre sub-leases and two of these are now in ore running 4% zinc-blende. At two of the shafts concentrating plants will be erected during the summer.——Farther south, the Carnation Mining Co. has succeeded in opening a new run of ore on a ten-acre lease that has been developed by sinking three shafts into the orebodies found at the 160 and 240 ft. levels. The operators have taken an option upon 30 acres of the Cosgrove land adjoining the Church-Mitchell mine, and will drill the tract during the early spring months. A concentrating plant will be erected to mill the ores from the shafts already sunk.——On an adjoining tract the Martha E. Mining Co. has developed a ten-acre lease to the producing stage and has let the contract for the erection of a concentrating plant.——At Carthage, L. P. Benua has revived the old camp northwest of the city by drilling the land and discovering the heaviest run of lead and zinc ore ever penetrated by drills in the Missouri-Kansas district. The drilling showed ore from 35 to 198 ft. The ore in the upper levels was exceptionally rich pebble ore, while beyond 90 ft. the ore became disseminated in a brecciated black and blue chert. This has stimulated prospecting until there are drill-rigs at work on the Garlinger, Thomas, Porter, and Chautauqua lands.



Sketch Map Showing Position of Joplin.

Joplin, March 18.

KANSAS.

CHEROKEE COUNTY.

Northwest of Galena the United Zinc Co. has re-opened the old Playter mining camp and has discovered an extension of the orebody toward the northwest. Prospecting carried toward the east has also demonstrated the ore in that quarter. The company is developing the new finds by running out drifts from the old workings preparatory to re-opening the mills.——Southwest of the city, Horning and Shomon have developed leases on Spring river, where the drills showed a 16-ft. face of ore underlying a good portion of a 40-acre lease. The development of the lease

was carried forward by sinking two shafts. In this the water proved a hard problem, and it was only after installing a pumping plant of 2000 gal. per min. capacity that the shafts were finally put down into the ore. The pumps still have to handle 1000 gal. per min. to facilitate the drifting. The ore worked runs high in zinc, with a smaller percentage of lead. A concentrating plant will be erected. ——The Wyandotte land, southwest of the city, and for years one of the heaviest producers in that field, is again shipping ore. The water overcame the operators a few years ago, when through a cave-in the surface waters from a small stream flowed in, utterly filling the tract to the mouths of the shafts. So extensive were the workings down to the 60-ft. level that the task of pumping out the ground became too great for the small, unorganized operators, and the land was abandoned. Cush & Montgomery, with associates, have recently flumed the stream across the land and have erected a central pumping plant to drain the entire tract. Drilling has shown that there are yet two runs of ore below the old levels, at 100 and 120 ft., respectively. The water is now drained from the upper levels and many of the old mines have been sub-leased to small operators, while a number of large operators will exploit the lower levels.——Another tract just now being opened is the old Cooper Hollow tract of 40 acres. This tract has produced ore from the surface to 90 ft., but the pumping plant that drained the land was upon an adjoining tract and, operations being discontinued, flooded the other tract up to the 48-ft. level. Gerster & Sumner secured the land and have put up a pumping plant to drain it. The land is honey-combed with shafts, and over 20 leases have been let to small operators since the re-opening of the tract. Six big producers are located on this land, and the development afforded by the draining of the lower levels will add a large output to the present production of the Galena camp. ——The Ricksecker Bros., with their associates, have recently developed a six-acre tract of virgin ground in the fifth ward of Galena. The ore is zinc-blende and occurs at the 75 and 135 ft. levels. The ore runs 21% zinc-blende. The ore will be hand-picked and treated upon hand-jigs.

Galena, March 18.

NEVADA.

ESMERALDA COUNTY.

A carload of ore assaying about $90 per ton has been shipped from Stimler, a camp 25 miles southwest of Goldfield. A shaft has been sunk to a depth of 83 ft. and a pay-streak 3 ft. in width has been opened up. The shipment was made from Blair to the Nevada-Goldfield reduction plant.——The main shaft in the Mohawk has reached a depth of 600 ft., and the ore-shoot has been developed for 500 ft. on the 450-ft. level, and good ore occurs in both faces of the drifts. Cross-cuts have been driven and ore of shipping and milling grade is being blocked out. A winze is being sunk from the 450 level, and it shows 5 ft. of ore of shipping grade. This winze will be connected with a cross-cut from the 600 level.

HUMBOLDT COUNTY.

(Special Correspondence).—Much attention is attracted to Lone Mtn., or Kraimer hill, two miles southeast of Goiconda. The entire hill and the territory adjacent to it have been located within the last two or three months, and work on several claims has resulted in finding rich gold-bearing quartz in veins which strike nearly north and south through this quartzite hill. The mineralization appears to be along porphyry dikes, though the porphyry itself does not seem to carry gold. The discoveries were made by L. K. Kraimer, who located several claims for himself and his Kansas City associates. Subsequently, seven leases were let on the group, and on these considerable work is in progress. The most work has been done on the Oswell & Butts lease, where a 75-ft. shaft was sunk, from which some drifting was done, outlining a 12-ft. vein, in which the ore assayed $50 per ton. The gangue is quartz, through much of which free gold is disseminated. The Beldon lease, on the same lode, has a 50-ft. shaft, in which some equally good ore was found. Then comes the Weiland & Noe lease, on which work is in progress. E. J. De Lano and associates of Los Angeles have six claims of their own, and three others under bond, situated on the south slope of the same hill, where the croppings are conspicuous. They have a small force of men developing. Roach and Ryan, prospectors and miners, have some promising locations.

Goiconda, March 14.

(Special Correspondence).—While it cannot be properly termed a new district, Seven Troughs, from an economic standpoint, is still in its infancy. Discovered in the spring of 1906, it has gradually but steadily increased in population and progressed in development until at the present time there are seven properties recognized as proved mines, with three of these on the shipping list. There has never been a boom in this section. All work has been carried on in a quiet conservative manner, and while many properties are incorporated as stock companies, there has been less wild speculation and stock-jobbing than in many of the newer districts. The principal mines at this time are the Seven Troughs-Fairview at Vernon, Mazuma Hills, Kindergarten, Seven Troughs Therein, Signal Peak, and Fine Gold in Seven Troughs canyon, and the Little Hero at Farrell. Several other properties have prospects that give promise of developing mines. The Seven Troughs-Fairview is opened to a depth of 500 ft. A vertical shaft with levels at intervals of 50 ft. has shown the vein to continue to the lowest point of development. The lode is large with good milling ore, and has a 6-in. seam on the hanging wall of exceedingly high-grade material. On a recent run of 500 lb. of ore selected from this seam the net returns amounted to $3000. A carload shipment is now in transit to Salt Lake.——The Mazuma Hills Mining Co., the largest shipper to date, has sent to the smelter seven carloads of ore that runs well into the hundreds. A lode averaging 4 ft. wide and assaying more than $30 per ton is opened through two adits, each over 600 ft. long, and a winze to a depth of 90 ft. In all, the workings have reached a depth of nearly 300 ft. A 10-stamp mill is being erected by the company.——Lessees on the same property are also uncovering some good ore. On the Hayes-Reagan lease, a lode 2½ ft. wide was followed from the surface to a depth of 100 ft., and produced a carload of ore running over $300 per ton. Since this shipment a cross-cut from the 160-ft. level encountered a shoot of sulphide of high grade. A flow of water coming in soon after caused operations to be temporarily suspended at this point, but is now being handled by a 6-hp. Gould pump.——The Kindergarten has demonstrated to a depth of 200 ft. its three feet of $50 ore, and assures a steady run to the 10-stamp mill in course of construction. Three carloads of ore shipped last spring and summer has paid for the development of the mine and placed enough money in the treasury to liquidate all expenditures in the erection of the mill. The other properties mentioned have well defined bodies of milling ore in sufficient quantities to extract profitably.——While there has been no extensive geological research, it is generally accepted that the mineralized area is the result of extensive fissuring and shearing of the eruptive rocks. The ore-bodies occur as chimneys in the lodes formed on the contacts of a light yellow rhyolite and intrusive basalt, which is found in a series of parallel dikes having a north and south strike and varying in width from a few inches to several hundred feet. In the oxidized zone the vein-filling is a breccia resulting from the shearing of the rhyolite walls and re-cemented by an infiltration of quartz and limonite. This condition in most instances extends to a depth of from 100 to 150 ft. before the sulphide comes in with pyrite, arsenopyrite, and some stibnite. Ruby silver occurs, making the weight of silver about equal to that of the gold. Calcite occurs in the veins as an alteration product of the basalt walls.——The only exception found thus far to the general north trend of the productive veins is that of the Kindergarten, which extends into the Therien through the Stoker lease, in a western direction almost at right angles to the other lodes. Water has been the chief trouble for the small operator, but the larger institutions have no difficulty in disposing of it with small pumping plants, and it is generally conceded that the discovery of

water at no great depth will be an advantage rather than a detriment to the camp.——With two mills under construction and a custom plant promised in the near future, it is expected a steady production of bullion will be turned out in the next few months.

Seven Troughs, March 22.

LANDER COUNTY.

(Special Correspondence).—The Copper Canyon mine, situated 20 miles southwest of Battle Mountain, now the property of the Glasgow & Western Exploration Co., was operated as early as 1875, and was noted then, as it is now, for high-grade ore in the form of cuprite, with native copper. Shipments were being made till last November.——The Golden Era mine, 8 miles from Battle Mountain, is owned by J. H. Durst and C. A. Snow of San Francisco, the latter being in charge of the work now in progress. It is a gold property and has 1000 ft. of shaft and adit work. A gasoline engine is to be installed and a 10-stamp mill, for amalgamation and concentrating, will be installed during the coming summer. The group contains three parallel veins, all of which are being opened. The gangue is an altered rhyolite and porphyry, the gold therein being mostly free, although there is some calaverite. The country is diorite.——The Little Giant, adjacent to Copper Basin, 10 miles southwest of Battle Mountain is a silver-lead property, managed by J. C. Orwin and associates of Salt Lake. The ore is a carbonate and of high grade.—The Lucky Strike mine, at the head of Trout creek, is a new property, discovered a year ago, now owned by Salt Lake people, represented in Battle Mountain by E. P. Stevens. The ore consists of galena, accompanied by silver. Several cars of it were shipped that ran 65% lead and 80 oz. silver. They have four cars now ready for shipment. The vein is 3 ft. wide and is developed by a 100-ft. shaft.——Another mine in Copper Basin is the Pedro, purchased some time ago by Langley-Trimble Co. of Tonopah. It is developed by a 150-ft. cross-cut to the vein, on which is 100 ft. of drift. The vein, said to be 30 ft. in width, consists of quartz and porphyry carrying free gold, and iron sulphide containing gold. It is proposed to install a hoist and erect a mill. The former owners are Lemaire Bros., Lee, and McDonald. A new working shaft is to be sunk.——In Willow Creek canyon, parallel to Copper canyon, is the property of the Eldorado Gold Mines Co., the work being in charge of Alex Walker of Colorado. A new shaft is being sunk, over which a hoist will be installed. The ore is gold-bearing, a shipment of which last fall averaged $38 per ton.——In Galena camp, 14 miles south of Battle Mountain, is the gold and silver property of the British-Nevada Syndicate, on which some new work is to begin this spring. Galena was an active place in early days.——The Dean mine and mill, on Lewis Mtn., 18 miles southeast of Battle Mountain, are in charge of D. J. Bosfield, who carries on some operations each season. The ore carries gold, and the property was opened and the mill built several years ago.

Battle Mountain, March 18.

LYON COUNTY.

A contract has been let to the Kaeding Construction Co. of Goldfield to design and erect a 40-ton reduction plant for the Ramsey-Comstock Mining Co. of Ramsey, Nevada.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Enterprise mining district has been organized, embracing an approximate area of 30 miles square, on the south half of the Colville Indian Reservation. It includes Meteor, Columbia, Hall Creek, and Twin Lakes camps. A. B. Nickens, of Covada, was elected recorder and will establish his office at that place.——The Faithful-Surprise Mining Co. has resumed active development work. During the past five years only the annual assessment work has been done. The mine has been opened by a shaft and two adits, intersecting and running on the vein, and the two levels are connected by a raise. About 1600 ft. of work in all has been done. The lower adit, when connected with the shaft, will give a depth of about 300 ft. on the vein. The company will drive a lower adit, to gain a depth of about 500 ft. S. L. Boyer has been appointed manager.

Republic, March 21.

OKANOGAN COUNTY.

(Special Correspondence).—The Nighthawk Mining Co. has purchased the mill, electric light plant, and Riblett tramway of the Grand View Mining Co. and removed them to the Nighthawk mine, on the Similkameen river, where they are being re-installed.——A small force is employed at the Ruby mine, and the company is shipping ore to the smelter.——The Judge Mining Co. is applying for U. S. patents for its claims on Palmer Mtn. The Judge group has considerable merit, but is idle at present.——The Triune mine, in Golden camp, is to be worked by a larger force.

Gold Bar Mine and Mill, Near Rhyolite, Nevada.

It has produced considerable high-grade gold ore.——The Bank of Montreal is reported to have sold to New York people the Dividend mine, comprising five claims on the west bank of the Similkameen river, about three miles north of Oroville. The property, for a long time idle, has been opened by over 200 ft. of adits, drifts, and raises, and considerable backs of ore are ready for stoping. A large tonnage of ore on the dumps is ready for treatment. With the mine is a 10-stamp mill on the east bank of the river, equipped for concentrating, amalgamating, and cyaniding. The Owasco Gold Mining Co. is said to have been organized to take over the property, and will shortly begin to operate it on an extensive scale. The mill will be overhauled, and will be operated by electric power.

Nighthawk, March 23.

CANADA.

BRITISH COLUMBIA.

The recent developments of good ore on the lower levels of the Centre Star and War Eagle, and the favorable results of diamond drilling, have made it necessary to continue the present workings to greater depths. The main shaft is to be deepened from the 14th to the 16th level, which will give a total depth of 2400 ft. on the lode. Good ore has been found on the Blue Bird, which is now 4½ ft. wide in a well defined vein.——The following ore shipments have been made during the week: Rossland mines: Centre Star, 3512; Le Roi, 1680; Le Roi No. 2, 665; Evening Star, 35 tons. Boundary district, 24,440; Slocan-Kootenay district, 1622 tons. The smelter receipts are as follows: Granby, 24,440; Trail, 4765; Le Roi smelter at Northport, 1444 tons.

Special Correspondence.

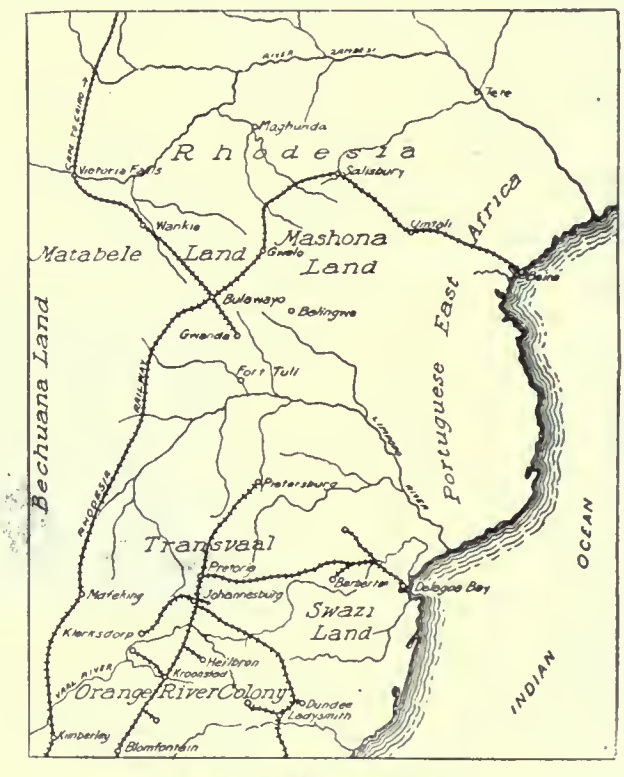
LONDON.

Consolidation of Farrar Group.—Rand Finance.—The Edward Medal.—Exploration Co.'s Bad Luck.—Australian Smelting Corporation.

For several months it has been known that the companies constituting the Farrar group, working east of Johannesburg, were to be amalgamated, if a scheme could be arranged that would be likely to suit the shareholders of the various companies. Such a scheme has now been put forward, and as it has met with the approval of some of the leading shareholders, there is every probability that it will be accepted generally. The Farrar group consists of the East Rand Proprietary Mines, which is the parent company; the H. F. Co., which has an interest in the East Rand Proprietary entitling it to 25% of the profits, and nine subsidiary companies owning and operating individual mines, namely, the Cason, Angelo, Dreifontein, New Comet, Cinderella, New Blue Sky, Angelo Deep, Dreifontein Deep, and Hercules. The first four are producers, and their outputs during 1907 were respectively, in ounces of gold: 190,975, 159,582, 104,489, and 91,578, while the other five are in process of development. The scheme for amalgamation is to increase the share capital of the East Rand Proprietary from £1,000,000 to £2,500,000 and to give certain proportions of new shares in exchange for shares in the subsidiary companies. The shareholders in the H. F. Co. will receive 333,333 new East Rand Proprietary shares. The shares due to holders in the subsidiary companies will be exchanged according to the relative present value of the several shares. The East Rand Proprietary is, of course, a large shareholder in the subsidiary companies, but these shares are canceled in the amalgamation. The market value of the East Rand Proprietary shares is taken at £3 13s. 9d., and that of the Angelo at £3 7s. 6d. There are 625,000 Angelo shares, of which 427,580 are held by the East Rand Proprietary. The remaining 197,411 shares are held by other people, who will receive in exchange 180,681 of the new shares. It is not necessary to go through the similar details of the other companies, so I will sum up by mentioning that the total new shares to be issued are 1,405,897, leaving 94,103 of the new shares held in reserve for future issue. Arrangements are also made whereby the new shares given to the shareholders in the non-producing companies shall not rank for dividend for a year or more, according to circumstances. There are a number of advantages to be gained by consolidating these interests. For one thing, the non-producing subsidiaries will be placed in a position of affluence by the possession of working capital obtained from the producing mines. It has been found difficult to raise funds for the development of the non-producers, and this consolidation of interests will make the whole group self-supporting. The scheme also will make for economy both in business organization and staff, and in the methods of handling the ore.

The first Edward medals were awarded this week to two miners, one from Newcastle district and one from South Wales, for bravery in rescuing comrades at the imminent risk of their own lives. This new decoration was instituted last summer by the King, and the announcement relating to it was made during his visit to Cardiff. The medal ranks equally with the Victoria Cross, and may be awarded to miners in any part of the British Empire who show conspicuous bravery. The medal is to be presented personally by the King, if in Great Britain, or by his governors, if in a colony or dependency. These are the days of cheap sneers at sentiment, and many superior persons think lightly of human emotions. It is well therefore to thank the King for the institution of this decoration and for his readiness to receive personally the humblest among his subjects. There are over a million men in Great Britain engaged in mining operations, mostly in connection with coal mining, the most dangerous of all branches of this work. They carry their lives in their hands, not knowing, when they descend, whether they will return. Apart from the danger, their occupation is also both arduous and unattractive. The miner is often of rough exterior and of uncouth speech, but is full of genuine emotions and ever prepared for self-sacrifice. So, for once in a way, let us forget the sordid laws of political economy and give a few kind thoughts to the heroes of the mine.

The melancholy state of the mining market is well reflected in the report for 1907 just issued by the Exploration Company. With the exception of



Map of the African Goldfields.

the El Oro and Tomboy companies, everything has been going wrong with the investments and speculations of this company. Mining men are all sorry for Mr. R. T. Bayliss, the chairman, and that the force of circumstances should have gone so much against him, especially as the chairmanship of the company was not sought by him. He took it some six years ago as a matter of duty, with the hope of repairing the damage done by previous managers and putting the company once more on its legs. During the last few years the profits have unfortunately been largely reduced by the recurring necessity of writing down the assets on account of depreciation, but during 1905 and 1906 there were sufficient balances of profit to enable the company to declare 5% dividends. The year 1907 was more disastrous still, for not only was it necessary to provide for depreciation, but losses were made on the ordinary transactions. The losses due to depreciation amounted to £158,418, of which £73,418 was due to the decline in South African gold mining shares and real estate, and £85,000 due to the depreciation in various copper company's shares, chiefly Amalgamated and other Montana companies. In the profit and loss account there is also an item of £56,000 due to losses on realization of some of these copper securities.

Another item of loss was £18,428 expended on the Maravillas copper mine in South America, which had to be abandoned. The net loss on the year's revenue account was £32,458. The outlook for the company is at present decidedly blank.

In your issue of February 1, I gave an account of the threatened reconstruction of the Australian Smelting Corporation, and mentioned that there were some hopes of the shareholders escaping assessment after all. These hopes are apparently being justified, for negotiations are taking a satisfactory course for the subscription of the necessary money in Australia. A scheme has been formulated which is to be submitted to the shareholders and debenture-holders. The terms are rather severe on both classes of present holders, and in all probability there may be some who would prefer the assessment. The scheme provides for the formation of a new company, of which the nominal capital shall be £70,000, in 140,000 ordinary shares of 10 s. each, 125,000 of 7% cumulative preference shares of £1, and £100,000 of 5% mortgage debentures. The 140,000 shares of 10 s. each are to be given to the holders of the 140,000 ordinary shares in the present company. The holders of £87,000 debentures in the present company are to receive £65,250 in debentures in the new company. The Australian people, whose names it is not desirable to divulge as yet, are to subscribe for the remaining £34,750 of debenture and £75,000 of the preference shares, thus providing the company with £109,750 in cash. The remaining 50,000 preference shares will be under option to the subscribers for two years at par. It remains to be seen how this scheme will be regarded by the shareholders and debenture-holders.

GOLDFIELD, NEVADA.

A Custom Plant.—Cyaniding in the Mortar.—Concentration.—Tube-Mill.—Filter-Presses.

The mill of the Nevada Goldfield Reduction Co. is treating 100 tons of ore per day, most of which comes from Goldfield mines, though a small tonnage is brought in sacks from Rawhide. A description of the plant may be of interest, as the present arrangement and method represents a considerable change from those of a year ago. The crushing and sampling department does not depart essentially from that seen in other sampling plants. The mill operates as a custom plant and the sampler is an important feature. The ore passes to the mill proper reduced to one-inch size and finer. It is fed through automatic feeders to four 5-stamp batteries of 1250-lb. stamps, discharging from the mortars through 16-mesh screens. The battery water consists of a dilute cyanide solution. The pulp flows thence over amalgamating plates, on which the recovery of the gold and silver ranges from 7 to 50%, according to the character of the ore. From the plates the material passes to Wilfley tables, the concentrate from which is mostly a heavy clean sulphide. These tables are so arranged as to yield a fairly good separation of the sand from the slime. The sand is reground in a tube-mill, which reduces it to 100-mesh, discharging upon a second set of amalgamating plates, thence by Frenier pumps to V-shaped classifiers. The heavier product discharges through the bottom of the classifiers to a series of vanners. The overflow from the classifiers passes to slime-vanners. The slime that is parted from the sand on the Wilfley tables also passes to the plates, on which it joins the tube-mill product. The sand passing over the vanners makes a light low-grade concentrate from the oxidized ore and a heavy high-grade concentrate from the sulphide ores. The tailing and middling from these vanners pass to the sand-vats for leaching; the slime-vanners, which handle the overflow from the classifiers, make a flocculent concentrate and pass the tailing to the agitator-vats. There are eight sand-vats and four agitator-vats. When the material reaches these, the solution receives additional cyanide. The agitator-vats are each 22 ft. diam. and 20 ft. deep, the agitating being effected by mechanical stirrers and centrifugal pumps. The slime from the latter is passed to a storage vat and thence to Butters filters. The solution from the filters is clarified by passing it through a Davis filter-press before it flows to the zinc-boxes. The precipitate is treated with SO_2 gas to take up the zinc. The mill contains an auxiliary plant for treating high-grade ore and for material requiring longer than the usual time for leaching. E. S. Leaves is general superintendent, and A. M. Smith mill superintendent.

Nevada-Goldfield Reduction Co.'s Plant.

Mizpah Shaft of the Tonopah Mining Co.

It is understood that after careful tests C. W. Merrill has decided that the filtering device used by him so successfully on Homestake ores is unsuited to the Goldfield ore. The tests were made at the plant of the California Ore Testing Co., in San Francisco, with the co-operation of F. L. Bosqui, who is acting as consulting metallurgist to the Goldfield Consolidated Mines Co. Labor conditions have improved very much, and it is expected that the construction of the new mill, furnished by the Allis-Chalmers Co., will proceed rapidly.

JOHANNESBURG, TRANSVAAL.

Gold Output.—The Labor Supply.—An Earthquake. —Keir Hardie.—Revision of Gold Law.

The returns for January show that the output of gold for the month was 560,329 oz., valued at £2,380,-124, which is a decrease of £98,535 compared with December. There was 40,000 oz. of gold, however, in the December declaration which really belonged to the reserve account, so that for actual production the January output was really 17,000 oz. ahead of December. The Rand's production was 540,202 oz., valued at £2,294,632. During the month there were 8775 stamps at work in the Transvaal, of which 8410 stamps were running on the Rand. The following figures are eloquent of the remarkable advance of the Rand since the end of the war. The total yearly production is as follows:

	Oz.	£
1901 - - -	288,994	1,014,687
1902 - - -	1,707,601	7,253,665
1903 - - -	2,995,749	12,589,248
1904 - - -	3,779,621	16,054,809
1905 - - -	4,897,221	20,802,074
1906 - - -	5,786,617	24,579,987
1907 - - -	6,451,384	27,403,738

The premier position for January is taken by the Simmer & Jack mine, with an output of 25,383 oz., valued at £107,820; second on the list is the Robinson, with an output of 25,304 oz., valued at £107,485; the third producer is the Robinson Deep, with an output of 20,592 oz., valued at £87,469. The labor position for January is quite satisfactory, as all of the departing coolies have been replaced by Kaffirs. There appears to be no danger of an immediate shortage of labor. The extra efforts being made all over the country have something to do with the satisfactory state of the labor market, but the real cause is the fact that the depression which has hung over this sub-continent so long, resulting in considerable retrenchment in industrial, commercial, and municipal undertakings, has led to the gradual concentration of natives from all parts of the country to the only work left for them, namely, on the Rand gold mines. There has been considerable curtailment of operations in the diamond mines, and at De Beers alone 7000 less natives are now at work than were employed a year ago. It is to be feared that the very satisfactory state of the Kaffir labor market on the Rand is temporary, and that the danger of a shortage is still with us. It is this very uncertainty of the labor supply that does so much to keep the Rand back.

It is now believed that the Rand can boast of a genuine earthquake tremor. Some nights ago there was a distinct shock felt in the Central Rand by many people. It was explained on the supposition that there had been a big fall of rock in one of the mines, and the Village Main Reef mine was selected as the scene of the eave. The manager, however, stated that no fall of hanging had taken place in the mine, and that another theory must be sought. Unfortunately, there is no seismograph on the Rand, but it is now generally held that there was a slight earthquake tremor.

So far, Keir Hardie, one of the labor leaders of England, has met with a warm reception on his visit to South Africa. In Durban the meeting was so rowdy that he was not allowed to speak. When he appeared on the platform he was greeted with yells of "Traitor," and the noise was so deafening that no one could speak. He was escorted back to his hotel by a strong body of police. There is no question of the unpopularity of Keir Hardie in South Africa. He is considered a meddling ignorant sentimentalist, and the labor leaders showed very poor judgment in asking him to come here. It is expected that his reception on the Rand will be almost as warm as in Durban. Whether he has come out with the idea of working up another strike is not known, but if he proves as complete a failure as the imported Australian agitators, there is little fear of trouble in the future. The men have had enough of striking for a while.——The discussion over the revision of the gold law has commenced, and it is probable that when the question is brought up at the next session of the Transvaal Parliament, there will be many important additions to the law. It is felt that there should be greater rewards for prospectors, and that the law should be framed so as to give the 'poor man' more of a show in the mining of the country. ——What will probably rank as one of the worst mine accidents in South Africa has just occurred at the Glencoe colliery in Natal. All the facts have not yet reached Johannesburg, but it looks as if 72 lives will be lost through this disaster—12 Europeans and 60 natives. A telegram from the manager of the colliery attributes the disaster to an explosion of fire-damp. After the first explosion rescue parties entered the mine, but unfortunately there were further explosions, and the rescuers were entombed. Among the rescuers was W. Muir, the deputy Commissioner of Mines.

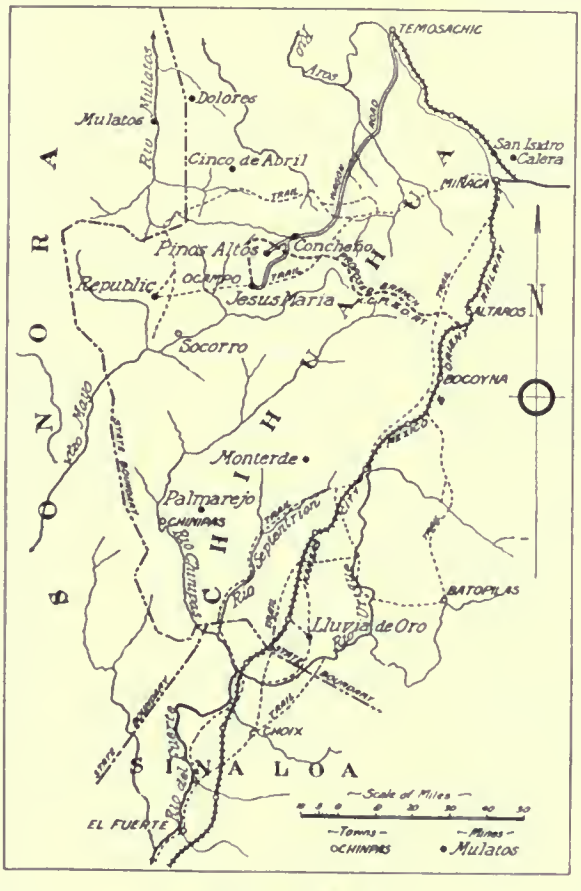
GUAYMAS, MEXICO.

Railroad Building.—The Yaqui & Pacific.—Hasty Construction.—Kansas City & Orient.—The Calabacillas Mine.—Lluvia de Oro.—Activity in Sinaloa.

The building of the so-called Cananea, Rio Yaqui & Pacific Railroad is proceeding rapidly. That is, 'rapidly' for Mexico. Considering the remarkably easy country through which the road is going, no records are being made at all comparable with those made by the transcontinental roads in Montana some twenty years ago. The rail-head is now about 30 miles south of San Blas, the junction with the Kansas City, Mexico & Orient road. At the time of writing the road is only opened as far as Navajoa, on the Mayor river. The Alamos branch has been open for some months. It is reported that construction is being pushed both north and south from Mazatlan and Culiacan, and that fair speed is being made. So far as can be learned, construction goes forward from six heads in the Sinaloa-Sonora section, two heads from Mazatlan, two from Culiacan, one from San Blas, and one on the Yaqui river branch. Owing to the absence of real newspapers in Sinaloa, it is very difficult to learn the actual condition of affairs. My own observation indicates that the preliminary construction is crude, all cuts more than a metre deep being 'shoo-flied,' and gulches crossed on cribbed ties. The efforts seem to be concentrated on moving the rail-head forward, and the exigencies at the front keep the rails so constantly occupied that the completion of the line behind is slow.

All work on the Kansas City, Mexico & Orient Railroad in Sinalao has been suspended for some months. Grading has been completed as far as the Choix river for a long time, but traffic is opened only as far as Joyaneo or the Fuerte station. This station was established several years ago, and since then little effort has been made to push construction. To those working in the Distrito del Fuerte this is a matter of great regret, as a number of mines would now be working if transportation facilities were improved. The completion of the road to the Choix river would also greatly help the mines of the high Sierra in getting access to the Pacific Coast markets. This much needed improvement in transportation is not looked for this year.

It is feared that the sale of the Calabacillas mine may not be consummated. The final payment became due when the panic of last autumn disarranged so many financial plans in the United States. It will be a matter of sincere regret to the many friends of W. A. J. Underwood, one of the active promoters of the enterprise and the actual manager, if the sale does not go through. The option was obtained on favorable conditions and the development of the mine showed promising results. Normally there would have been no difficulty in raising the funds necessary for compliance with the terms of the option. The mine contains, in addition to the new ground opened up by Mr. Underwood, large reserves of low-grade material left by the Mexican owners in their gophering for the high-grade streaks. Mr. Underwood has worked like a Trojan for the last two years on this enterprise, and all hope that he



Map of Part of Mexico.

will succeed in putting the deal through.——It is reported that Messrs. George Holmes and White have secured control of the Guadalupe mine at La Cumbre de San Manuel. Mr. Holmes is working about 100 men preparing to transport the ore over a wire-rope tramway to the Poche mill. The ore is to be treated by amalgamation and cyanidation. The management of the Lluvia de Oro is wrestling with the transportation problem in assembling its new equipment. A tremendous amount of material yet awaits shipment from Joyanco to the mine. A wagon-road was recently completed from Choix to the Fuerte river. The machinery is being carried to the river and is then rafted some miles up-stream to the foot of a narrow wagon-road that winds down the side of the barranca from the mine. The equipment is very heavy, and it is considered improbable by local people that the building of the mill will be completed this year.

It is reported that once again the Jesus Maria mine at San José de Gracia is in bonanza. These mines are periodically reported as being worked out, but apparently they never give the last gasp. It was stated by an official connected with the company that at the present time the bullion shipments amount to $100,000 monthly.——In spite of the financial flurry in the United States, a number of American companies continue exploration, and apparently with satisfactory results. The Sierra Madre M. & D. Co. is working at Pino Alto, Sabinito, and Las Yedras. Harry Maude is working at Los Cueros and some Denver people are investigating property near Placeres, on the main Calabacillas and Fuerte trail. A number of Americans are prospecting in the Fuerte and Morelos districts, whether for themselves or for companies is not known.

SALT LAKE, UTAH.

Revival at Mercur.—Other Gold Districts.—The Newhouse Co.—Tintic Smelter.—Utah Copper Co.—Shipments From Tintic.

There are indications of a revival in the Mercur district; the announcement of a resumption at the Sunshine mine has served to renew confidence in the low-grade gold properties of the camp. Several years ago, the Overland mine was operated successfully for a time, but it finally proved to be a failure owing to refractory conditions found at depth. The Sacramento Co. is doing exploratory work with the hope of finding new bodies of the cinnabar ore that has been so profitable in times past. The Consolidated Mercur is, of course, the mainstay of the camp, and is producing about 800 tons of ore daily, from which is being recovered between $30,000 and $40,000 monthly.——The newest gold camp in the State is Gold Springs, in Iron county. The Jenny Co. is conducting the principal work at the present time, and is operating a small mill. At Stateline, a few miles away, there are symptoms of a decided revival. Here lessees working in the Ophir mine are meeting with success. In the Deer Lodge district, which is really a portion of the Stateline and Gold Springs mineral belts, but situated just over the line in Nevada, several new companies have been formed recently and are preparing to undertake active development. Salt Lake and Eastern parties not long ago acquired title to the Snowflake and other properties, in the name of the Buck Mountain Mining & Milling Company.

Local minority shareholders, representing 44,700 shares in the Newhouse corporation, have requested representation on the board of directors, and assurance has been given by Samuel Newhouse that the same will be granted. Accordingly, ex-Governor Heber M. Wells has been invited to become the representative, and he will undoubtedly be chosen at the next annual meeting, which occurs in New York on the 27th inst. During the conference with Mr. Newhouse, Lafayette Hanchett, the manager, explained that at the present time the company is marketing 600 tons of ore daily and producing copper on the basis of 600,000 lb. monthly, but that the output will shortly be increased to 1,000,000 lb. The mine is opened to the 800-ft. level, and there is no reason to doubt that it is one of the most valuable copper mines in the State.

The annual report of the Carisa Mining Co., operating in the Tintic district, has been issued, and shows net earnings last year of $78,649, obtained from 7,481 tons of ore. The smelting companies were paid $31,320 in treatment charges; the railroads received $30,054 for freights, while $34,614 was paid out for labor. The physical condition of the mine is reported as being fairly satisfactory; but the management recommends exploratory work below the 1000-ft. level. Except the ore taken out by lessees, no shipments have been made this year on account of the low price of metals.——The construction of the new Tintic smelter is progressing at a most satisfac-

tory rate, and the fact that the management has ordered equipment sufficient to operate a plant twice the size originally planned indicates that the builders are embarking in the smelting business upon a much more elaborate scale than was originally intended. As now planned, the Tintic plant will treat 800 tons of lead and 300 tons of copper ore daily by the end of June. The Minneapolis Steel & Machinery Co. has been awarded the contract for the steel building to contain the copper furnaces. The plant is to be thoroughly modern and complete in every respect. The company has begun to look around for contracts and has already tied up some of the principal producers in the Tintic district for a term of years. A representative has also been looking for tonnage at Pioche, Nevada.

The Utah Copper Co. oversold its spot copper in February to the amount of nearly 4,000,000 lb., or about what the March output of its mines will be. The ninth section of the mill at Garfield is now in commission, and the plant is treating 4500 tons of ore daily. Six steam-shovels are being employed at the mine, and they are moving between 11,000 and 12,000 tons of ore and overburden daily. The seventh shovel has been ordered.——The Boston Consolidated management is rapidly getting ready to supply ore to the mill at Garfield. On account of the shut-down last autumn much valuable time was lost. However, three sections of the Garfield mill are running, and the fourth will be started early in May.

The ore shipments from the Tintic district last week amounted to 49 carloads, the contributing mines and amounts being: Centennial Eureka, 44; Eureka Hill, 4; Bullion Beck, 1 carload.——The May Day mine will resume production next week.

GOLCONDA, NEVADA.

An Interesting Concentrator.—Gravity Not Used.—Description of Apparatus.—Excellent Results.

The concentrating plant of the Glasgow & Western Exploration Co., at Golconda, Nevada, is now operated by the American Direct Concentration Co., having been equipped with the devices of the latter company for separating the pyrite from the lime-garnet gangue by a method that is the reverse of gravity concentration on jigs and tables. This company is controlled by A. P. Stanley Macquisten and associates, who are also connected with the Glasgow & Western. The ore being run through the mill comes mainly from the Adelaide mine of the Glasgow company, 12 miles southeast of Golconda, and contains chalcopyrite running 4% copper. The ore is crushed to an average of 30 mesh by crushers, rolls, and Huntington mills. In the sizing and re-grinding and classifying that the pulp undergoes, the fine slime is separated from the sand and heavier pyrite by spitzkasten and Callow tanks, this slime being laundered down to settlers, the settled product being shipped to the smelter. The sand and its accompanying pyrite are then subjected to a flotation process, whereby the surface tension of the water that goes with the pulp causes the mineral to float and pass over the lip of a receptacle, while the lime-garnet waste settles, effecting a remarkably clean separation of the two. The equipment employed consists of 96 cast-iron tubes, each 6 ft. long and 12 in. diam., the interior of the tube being spiral. These tubes are arranged in 24 units of 4 tubes to each unit, all set horizontally. The four of each unit are placed end to end, the second being on a lower level than the first, the third lower than the second, and so on, permitting a continuous flow of pulp through the series. The tubes all revolve at the rate of about 30 rev. per min. The pulp, carrying with it a liberal supply of water, is fed into the head end of the first revolving tube, whose spiral corrugations carry it to the opposite end, where it discharges into an iron sand-box which constantly overflows, carrying the mineral with it. The flotation of the mineral on the surface of the water begins as the water and sand discharges from the tube. The sand settles at the bottom of the sand-box and passes through a spigot into the second revolving tube, then to the third and fourth of the series, each tube making a concentrate of its own. The first tube in the series makes approximately a 25% copper concentrate, the second 20%, the third 15%, and the fourth a 10% product. It is interesting and instructive to see the 24 units working, each enacting primary concentration, followed by three re-concentrations. The final tailing is remarkably clean, and the product has the consistence of a clean concentrate. The principle on which this method depends is the recognized surface tension of flowing water, but this is aided to some degree by making the water slightly acid by putting into it a small quantity of sulphuric acid. The addition of a little coal oil has been tried, and perhaps to some effect, but the mill superintendent, C. G. Smith, asserts that this is no really essential feature of the process. The process and the equipment necessary to its demonstration were worked out and devised by A. P. Stanley Macquisten of the Glasgow & Western Co., operating in Nevada, Utah, and Mexico. This company has a reverberatory smelting plant at Golconda, which may be re-modeled and equipped for modern copper smelting at a later date.

The Western Pacific, building from Salt Lake to San Francisco, has 230 miles of track laid from Salt Lake, 170 of which is in Nevada. The line first strikes the Southern Pacific at Wells, and continues in close proximity to the latter as far as Winnemucca. From there it strikes westerly, going around the north end of Pyramid lake, thence southerly a distance of 60 miles, then turning westerly, crossing the Sierra Nevada over Beckwith pass, which is 1900 ft. lower than the pass over which the Southern Pacific crosses this range near Truckee. The route goes thence down the middle fork of Feather river, then through a 7000-ft. tunnel into the north fork of the same stream, continuing through Oroville and Marysville, thence to Sacramento and San Francisco. The grading is complete 110 miles west of Elko. In making the detour south from the head of Pyramid lake this line comes within 20 miles of Reno.

Charles A. Green, who is mining high-grade antimonial ore in Bloody canyon, 14 miles from Mill City, has installed a 6-ton reverberatory smelting furnace at the property, which is ready to be blown in. His work in the mine shows 210 ft. vertical depth of ore, which occurs in lenses in the vein. In 1907 he shipped 450 tons of this ore on a guarantee that it would run at least 60% antimony, and it ran above that percentage. This ore is a sulphide, free from arsenic and other impurities except sulphur. Wood from the desert and canyons will be used as fuel for the furnace.——W. G. Adamson and associates, of Winnemucca, are developing properties of cinnabar ore in American canyon, El Dorado canyon, and in the Antelope range, north of Rosebud. Some excellent specimens of this ore have been brought to Winnemucca.

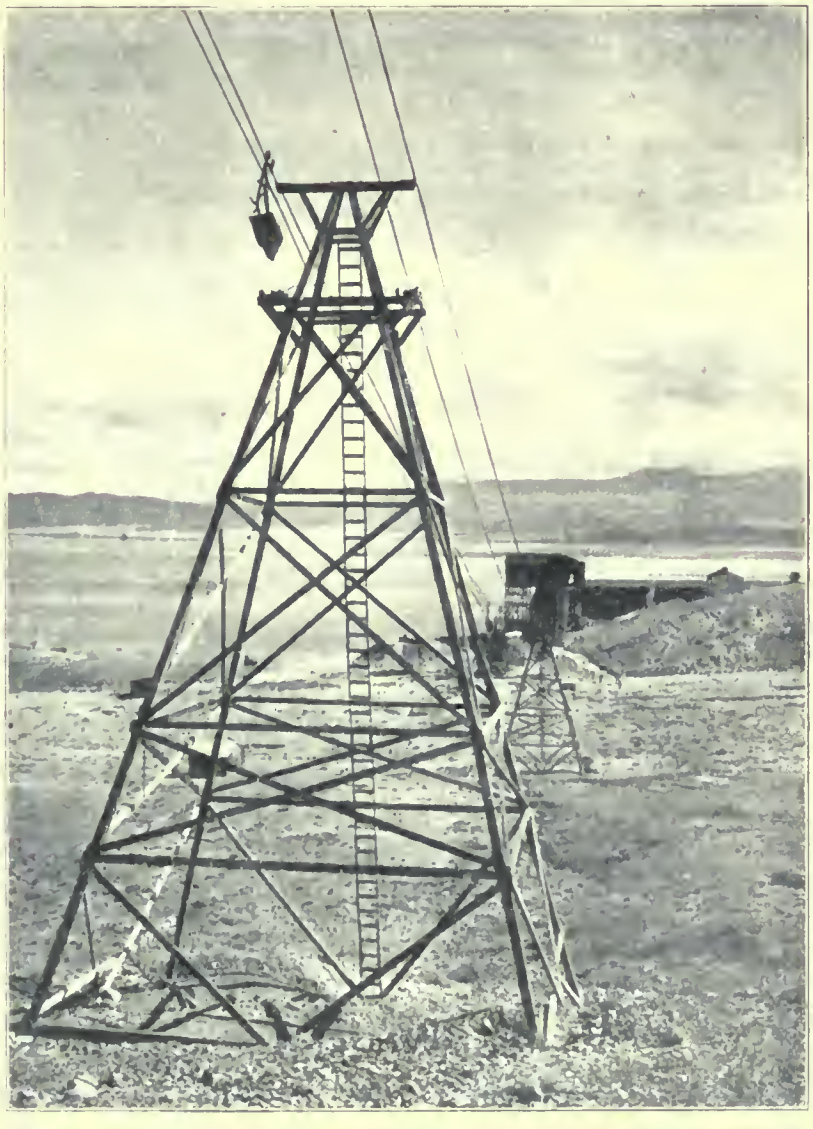
The Nevada Northern Copper Co., of South Dakota, has a location of 17 claims in Sonora range, 12 miles southeast of Winnemucca, and J. C. Fuller and David Payne, stockholders in the company, are on the ground doing some work. An adit is being driven on a vein of copper ore between limestone and porphyry. The gangue consists of shale, carrying copper, silver, and gold. The ore is a sulphide, in which native copper is visible. The mountain is high, and great depth can be attained by driving a short distance on the vein.

TONOPAH, NEVADA.

Pittsburg-Silver Peak Co.—Tramway and Mill.—Character of Ore.—Golden Circle.

The property of the Pittsburg-Silver Peak Gold Mining Co., at Blair, is just beginning the period of production for which preparations have been in progress during the past 18 months. The mine is well developed and equipped and the new 100-stamp mill is ready to operate at its full capacity. The Leschen aerial tramway, 2½ miles long, has a line of 124 buckets of 10 cu. ft. capacity, supported by steel towers, so that it can carry 40 tons of ore per hour. The mine terminal is 1600 ft. higher than the mill, the speed of the buckets being regulated by an oil-controller at the upper end.

The mine workings comprise those of the Mary, Mohawk, and Drinkwater, which originally were separate mines. Since their purchase and consolidation by this company the workings have been connected by 3600 ft. of adits and cross-cuts on the main working level, which is equipped with electric haulage. The three mines, now connected and operated as one, were locations on different parts of the same great vein, which strikes northwesterly through a schist and diorite, accompanied by dikes of alaskite. The vein has a dip of but 18 to 20° from the horizontal, and is estimated to have an average width of 10 ft. throughout the length of this group. Worked-out chambers and the faces of some of the stopes show the vein to widen to 30 and 40 ft. in places. The ore consists of a gold-bearing quartz, having practically no sulphides, those which do occur being iron and galena in small seams and pockets in the gangue. The Mohawk takes in a portion of the vein higher than the others and covers the apex; the Drinkwater was located still lower on the dip of the vein and farther northwest; the Mary, through which the main adit enters, occupies the lowest place on the dip of the vein. All the ore now exposed and blocked out stands above the haulage level, and the workings above it open 800 ft. of ore, measured on the dip. Present plans contemplate the sinking of an incline on the vein from the lowest level.



Steel Tower of Leschen Tramway of the Pittsburg-Silver Peak Gold Mining Co., at Blair, Nevada.

At the portal of the main adit a small electric-driven air-compressor is in use, and a 20-drill Nordberg compressor is being installed. The latter will be driven by a 300-hp. electric motor. This will give the company sufficient drill-power to break the large tonnage of ore required at the mill and to keep up development.

The ore is hauled from the mine in 3-ton cars direct to the bins, which discharge into the crushing plant, the latter consisting of a No. 6 and two No. 3 McCully gyratory crushers, reducing ore to 1½-in. size. The crusher plant and the upper tramway terminal occupy the same building. The crushed ore falls into bins, from which it is drawn through a chute, below which is an automatic loader for filling each tramway bucket as it passes that point. At the mill terminal the ore is distributed by a 180-ft. belt conveyor to the bins above the batteries. The latter are divided into five 20-stamp units, a 50-hp. electric motor supplying the power. The stamps are 1050 lb. each, dropping 7 in. 104 times per minute, the mortar screens are 35 mesh, of both the slotted and perforated steel type. It is figured that from 60 to 70% of the assay-value of the ore will be recovered on the amalgamating plates. The pulp from the plates flows to two main cone-classifiers, thence to a second set of ten cones. The overflow in each case passes to pulp-thickening vats, the heavy material to sand-vats. This feature of the plant consists of the Merrill system of cone-classifiers, whereby a good separation is made of sand from slime, the sand being cyanided in vats and the slime in the Merrill filter-presses. The precipitation is effected by zinc dust and the precipitate is collected in a triangular press.

There are 125 men employed at the mine. George O. Bradley is general manager; the mine superintendent is Geo. Skeavington; cyanide superintendent, Henry Hanson; foreman of stamp-mill, M. O'Rourke.

Gold Circle, in Elko county, is 50 miles northeast of Goleonda and about the same distance north of Battle Mountain. People are rushing into this camp by stage and automobile from Goleonda and Battle Mountain. Some also go in from Tuscarora. The new camp is close to Midas postoffice, which was established long before the ore in the adjacent hills attracted attention. The veins opened carry free gold in a quartz-porphyry gangue, and many rich specimens are brought out.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A second-foot is a flow of 1 cu. ft. per second, and is equal to 50 miner's inches. At Niagara the discharge is about 250,000 second-feet.

In the scorification assay, with mixture of pure silver and lead, an increase in the amount of silica present makes the loss of silver greater in the slag.

Bucket elevators have been used for elevating tailing, but are not satisfactory because the sand adheres to the buckets and wears the links.

The efficiency of the air-lift is dependent on the ratio of submersion to lift, and accordingly a double lift is economic in many cases to avoid expense in obtaining submersion.

A screw conveyor is the cheapest of all conveyors to install. A 9-in. screw, 100 ft. long, ought to be put up for about $300. All parts are subject to heavy wear, and repairs and renewals may easily amount to 100% per annum.

Aluminum is the most abundant of all the metals. It is an essential constituent of all important rocks except sandstone and limestone. The metal is expensive to reduce, the process being the electrolysis of bauxite dissolved in fused cryolite.

Structural steel encased in good concrete is safe from corrosion for many years, but in the case of cinder concrete, the voids often cause corrosion. If cinder concrete is to be used, it should be mixed well and wet, and it may then be trusted as much as stone concrete, so far as corrosion is concerned.

The ordinary pile-driver cannot be much improved in the matter of capacity. Steam drivers are successfully used, but the shorter period taken in driving does not materially affect the total capacity of a crew. The main cause of the limited output in driving piles is the length of time necessary to adjust the pile and the machine to the position required.

Tar and gravel covering is generally put on a roof of 1-in. boards laid on rafters, or else 3-in. plank, grooved and splined, laid directly on the roof girders. In making the roof, several layers of saturated wool felt are first put on, and then the surface is finally covered with coal tar pitch and a sufficient body of well screened gravel to give the desired surface.

Platinum occurs in certain copper-nickel ores of low grade in southwestern Utah and eastern Nevada. Near Bunkerville, in Lincoln county, Nevada, the occurrence is similar to that in the Sudbury district. The ore is said to contain 2½% of nickel and ⅓ oz. gold per ton, in addition to some copper. The deposits are situated 45 miles from Moapa station on the San Pedro, Los Angeles & Salt Lake railroad.

Placer ground has been profitably worked when only containing 2.52 c. per cu. yd. for the total material washed. In one case in northern California the amount of material washed down was 1,251,399 cu. yd., yielding $31,618. Of this amount, 86.5% of the gold was obtained from the sluices, 12% from the bed-rock ditches, and 1.5% from undercurrents. The profit obtained was $4106, as a result of nine months' work.

Whenever metal is subjected to corrosive gases in smelter buildings, the ordinary allowable stress should be decreased 20 to 25% and the minimum thickness of metal increased 25%, unless it is fully protected by an acid-proof coating. The minimum thickness of corrugated sheet steel for roof-covering should be No. 20 gauge, but where there is no danger of corrosion, No. 22 and 24 may be used for the roof and sides, respectively.

Dams in underground workings may conveniently be made of timber. A recess with smooth sides is cut in the drift, and horizontal balks of timber, preferably of oak, are carefully fitted in. These should be dressed and all cracks caulked. For this purpose shingles, driven in the inner side of the dam, are effective. For heavier pressures a special dam made of wooden logs placed longitudinally and wedged tightly is more effective than masonry dams, which are liable to crack if movements of the ground occur. Concrete dams are easily put in and are better than masonry work.

The drilling of oil-wells in California cannot be performed economically, owing to the hard shells which occur in the soft rocks. These must be passed through at an angle, which has a tendency to change the direction of the holes, causing much expense and trouble from crooked and caved holes. The machinery is heavier than that used in other districts, and thicker casing is necessary. In the Coalinga field, wells between 2000 and 3000 ft. deep cost from $20,000 to $30,000. The principal developed oil areas of California are in Kern and Fresno counties in the San Joaquin valley, and Santa Barbara and Los Angeles counties on the coast.

A good alloy for bearing purposes must consist of at least two constituents, namely a hard one to support the load and a soft one to act as a plastic support for the harder grains. The cheapest of the white metal alloys is lead and antimony. The eutectic mixture is composed of 87% lead and 13% antimony. As the antimony increases the alloy becomes brittle, but a slight excess gives better wear, as the hard grains of antimony are imbedded in the soft eutectic. Tin imparts the rigidity and hardness without increasing brittleness. Babbit metal is the most expensive of these alloys, consisting of 89.1% tin, 7.4% antimony, and 3.7% copper.

A conveyor of exceedingly simple type is used in the gold mills in Western Australia. It consists of a semi-circular trough about 60 ft. long, provided with a ladder-like frame, with blades hanging from the rungs, which is made to move horizontally to and fro on rollers. The blades are free to swing in one direction, but are prevented by a stop from swinging back farther than the perpendicular. When the ladder is traveling forward, each blade hangs vertically, and pushes a little heap of ore before it for a distance of 20 in., the length of the stroke. On the return stroke, the blades being free to swing, slip over the tops of the little heaps and on the completion of the stroke resume their original vertical position. To install a reciprocating conveyor 100 ft. long, capable of transporting 10 tons of ore weighing 150 lb. per cu. ft. would cost from $700 to $1200. This would require a 15-hp. motor.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Mill-Tests.

The Editor:

Sir—Descriptions have lately appeared in the technical press giving details of construction and apparatus of testing plants capable of treating large samples of ore. Some of these plants are in reality very complete reduction plants on a small scale, and can treat as many tons of sample, given plenty of time, as may be desired. In one of these descriptions the statement was made that small preliminary tests were made as guides for the large final test, and that the results of the large and small tests rarely differed more than 5%. I think this will be admitted to be the case in almost all testing works, and there is no question in my mind as to which test is the more nearly accurate or more nearly represents the results that will be attained in a proper mill. The larger or mill-test bears a very close resemblance to the first few days run of a new plant, during which the best results are rarely expected and never attained.

Recently a number of tests on lots of 200 lb. each have been made by Mr. Empson, preliminary to the design of a 1000-ton mill and cyanide plant at La Luz, in this State. The tests were numerous and exhaustive, covering fine-grinding, air-agitation, and concentration. Now if a mill-test were to follow these laboratory tests, it would be along the lines of the small test that gave the best result, and would add little if any to the knowledge of the ore already acquired. It may be said that the mill-test gives data as to the actual cost of crushing, but in the present case, where the mill will consist of 200 or more stamps, and, in fact, in any case where the projected plant will be much larger than the sample plant, a test in a small mill would appear to be of little use for this purpose. Perhaps an expression of opinion from those contrary-minded, with reasons for their opinions, will put me right, and be of interest to others.

MARK R. LAMB.

Guanajuato, March 8.

Drill Contest on the Rand.

The Editor:

Sir—I have read, with much interest, the article on the drilling contest at Johannesburg, as described in your issue of March 14. From the description of the mechanism of these drills, it is my opinion that the Gordon drill will not equal the Waugh stoping-drill for up-cast holes. It can certainly do better work than the Waugh drill on down-cast holes, drilling in a breast. I do not think it will do better work in vertical holes than the Waugh sinking drill. I cannot understand why the South African people do not stope their ground with up-cast holes. They may have got into this system through the inability of native labor to drill anything but a down-cast hole by hand. The entire contest was based on drilling an inclined hole in a perpendicular face, such holes as are used in breast-stoping, or running a drift. An up-east hole, or upper, is cheaper drilled, either by hand or by machine-drill, than any other type of hole, and usually can be so placed as to break ground as effectively as any other class of hole. I have tried air-hammer drills for drilling uppers, inclined holes for breast stoping or driving, and vertical holes for sinking, with the Waugh drill, the Hardsocg, and other types. They will drill uppers and straight down-holes splendidly, but they do not drill breast-holes effectively. The Gordon drill apparently does a class of work which it is impossible to accomplish successfully with any of the air-hammer drills as yet developed and placed on the market in this country.

MINE MANAGER.

Wardner, Idaho, March 3.

Snares for the Unwary.

The Editor:

Sir—In your issue of March 7, I notice your exposure of a so-called mining company, under the heading of 'Snares for the Unwary,' an exposure that I was glad to see, and hope that there is someone that is in a position and has the stamina to take action against any and all such wild-cat schemes, for they not only rob the poorer class of people who are trying to better their condition, but do legitimate mining an endless amount of harm: and I would like to see all such propositions, or rather, the men back of them, put where they belong, that is in State's prison. We brought to the attention of our last legislature the need of a law to make all such schemes a felony, and such a law was passed by both houses, but for some unexplained reason it did not become operative.

While I am writing, there is another thing that I would like to suggest, and as long as I am at the head of our corporation, it shall be the rule of this office: I believe that Congress should pass a law making it compulsory for the boards of directors of all corporations to report to the stockholders each and every month, or as often as they meet, a detailed account of the business done during the previous month. Some may say that it is too expensive to do that, but as you know, there are many inexpensive duplicating machines that will run anywhere from 100 to 2000 copies per hour at a cost of a very few cents, and they can be mailed at one cent each, and I am satisfied that there is not a stockholder anywhere that would object to the extra expense. There are many reasons that could be advanced in favor of the above suggestion, but I need only give one: I like to know what is being done with my money, and I think others are the same, and should have the same privilege.

I sincerely hope that the Industrial Investment Co. may not only be enjoined but suppressed completely, and all others of the same character.

W. C. FERRIS.

Benson, Arizona, March 10.

[We welcome this expression of opinion. Undoubtedly publicity is the best preventive of wrong financial methods.—EDITOR.]

Tube-Mill Lining.

The Editor:

Sir—In reply to the letter of Mr. C. E. Rhodes, in *The Engineering and Mining Journal*, I had written claiming the credit for the El Oro tube-mill lining for Mr. J. R. Brown, whose name until then I had not seen associated with this invention. A circular reached me from the Blaisdell Company of Los Angeles, acknowledging the origin of this plate, consequently I did not forward my contribution to the discussion in your paper.

In view of Mr. Rhodes' letter in your issue of December 21, 1907, I may possibly be pardoned for quoting this letter in part: "Tube-mills were first used at El Oro commercially on the completion of mill No. 2, about the beginning of 1905. The liners used were the chilled castings from Krupp's foundry, who supplied the mills. Subsequently liners were cast at the foundry of the El Oro company. Several innovations were tried, but it was not until about the beginning of 1906 that a sketch was delivered by Mr. Brown, who was in active charge of the tube-mills, to the mechanical department, then under my control. If I am not greatly in error, the idea of the corrugations on the plates was primarily to give the pebbles a chance of greater lift, and at the same time exposing a greater thickness to their abrasive action. I suspect, therefore, that, like so many other useful inventions, the wedging of the pebbles, forming a silex lining, was more 'by luck than by cunning'."

Mr. Rhodes is apparently not of this opinion. I give herewith a sketch of the original ribbed plate, as designed by Mr. Brown, which is very different from the amended plate as shown in the photographs. Presuming this was the case, I do not know that the consequent discovery of the wedging of the pebbles, forming a silex lining, detracts from the merit due to the originator, any more than the traditional discovery of the expansion of steam by James Watt, by an observation of the lid of the kettle, suffers discount from the fact that that gentleman did not place the identical kettle on the hob to observe the phenomena due to the generated steam. Both gentlemen profited by their observations.

Since writing the above I have noticed in the *Mining Journal*, London, in connection with the Waihi Grand Junction Co., Ltd., New Zealand, that there also a gentleman, named F. C. Brown, has invented a ribbed plate for tube-mill liners, described in the words of the chairman, as follows:

"The coarsely crushed ore passes direct into tube-mills fitted with Brown's patent hard iron-ribbed liners, and is reduced to the required state of fineness. The great economy and efficiency of mills fitted with these liners, I think, arises from the fact that the flint pebbles are lifted by the ribs and fall in a cascade, whereas in other mills the pebbles merely slip round on a smooth surface, grinding away to a great extent to waste. The first one fitted at Komata ran continuously for 18 months, having ground over 27,000 tons of intensely hard and very coarsely crushed quartz, the liners then only being partially worked away, and as since a further improvement has been made in design, it is safe to calculate the life of a liner is, at least, two years."

It would, therefore, appear (unless there is some connection) that these two gentlemen of similar name have developed along similar lines the ribbed liner. It would seem, however, in the latter case, that the part played by the pebbles in wedging themselves, forming a silex liner, has not been recognized or, at least, acknowledged.

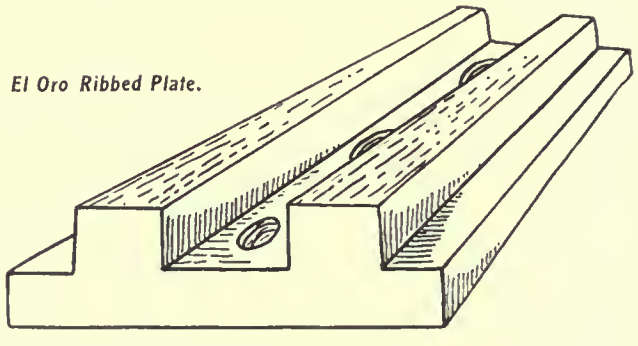
This similar evolution of the liner is not without interest, and renders plausible, if not probable, the remarks at the close of the above letter, regarding the prototype of the El Oro liner.

H. E. West.

Akmolinsk, Siberia, February 2.

The Editor:

Sir—In your issue of February 29, in an article by Mr. J. R. Brown on the ribbed form of tube-mill lining, Mr. Brown says: "Mr. Hardinge admits that his Mexican patent was issued to him under date of February 22, 1907, so we need not further pursue



El Oro Ribbed Plate.

the inventor of the conical tube-mill. * * * O. Crimmann and R. Riley obtained a Mexican patent, dated August 29, 1907. * * * If the lining really was used in Caesar's time, as Mr. Foote intimates, I give it up; but if at any later time, I claim it." Mr. Brown also says that it is his desire to sell at a small profit an "untainted lining" which mill-men may safely buy and use.

The inventor of the conical mill has not been aware of being the object of pursuit,* unless the article in your issue of December 21 (page 775) on this same subject was intended as such. In answer to the latter we must admit having written a reply, which finally found a resting place in our waste-paper basket, for which act of consideration to you and your readers, we accept their unrecorded thanks. As it is highly probable that this form of lining may in the future be of interest to users of tube-mills, and in order that Caesar and Brown may receive their due, we ask what Brown's U. S. patent has to do with Hardinge's Mexican, or his other foreign, patents covering the device?

Let us consider in chronological order, the claimants for the honors (dollars) for first prescribing a remedy or preventative* for the dyspeptic disorders to which the tube-mill is heir, as follows:

Foote claims no patent, but it is allowed that he is a philanthropic good fellow.

Hardinge first practically applied the rib form of lining to a 150-ton conical (tube) mill in January,

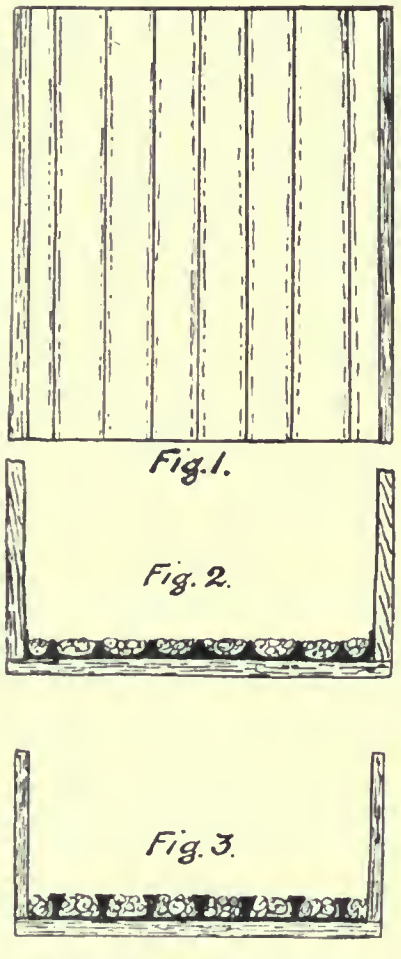
1906; he applied for U. S. patent for mill-lining long previous to June 13, 1906. The exact date is still an unpublished record in the U. S. Patent Office.

Brown applied for U. S. patent on June 13, 1906.

Riley applied for Mexican patent six months after the issuance of Hardinge's Mexican patent, covering conical mill and ribbed lining.

In this we do not wish to be understood as "pursuing" Mr. Brown, simply enjoying the parade of facts and figures from "up a tree" while dates are undergoing judicial investigation.

In an endeavor to repay the weary reader for his time, as well as affording me an opportunity to present my credentials for a perch upon the same philanthropic rail as that occupied by my co-worker,



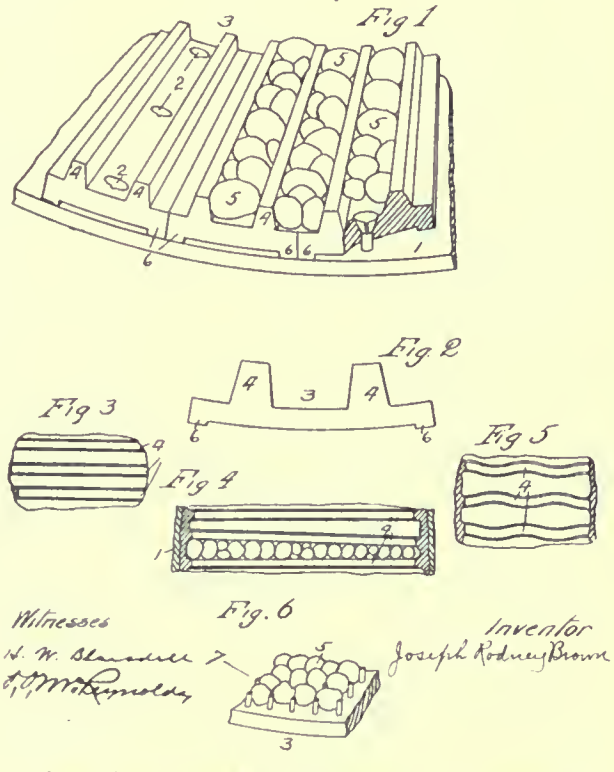
Lining for Bottom of Launders.

Mr. Foote, and not entirely malapropos to the above discussion, allow me to suggest that a satisfactory lining for launder bottoms can be made of light cast-iron plates with ribs about ¾ in. high and ¾ in. apart, spaced in staggered lengths of 3 or 4 inches as indicated in the accompanying sketch (Fig. 1 and 2), between the ribs of which the coarser sand will be retained, especially jig products, forming a lining that constantly renews itself, until the ribs themselves are worn away. This will be an order to the Public upon the El Paso Foundry to permit the use of my plans and blue-prints, from which they furnished several hundred feet of this lining in 1901—no patents applied for. The objection to the pointed form of rib shown in the sketch, is that the wearing away of the top portion gradually releases the enclosed particles, which ultimately drop out owing to want of adhesive walls. An improvement over my earlier style of launder plates is shown in Fig. 3, which, however, would be more difficult to cast and would consequently cost more.

H. W. HARDINGE.

New York, March 9.

[*Mr. Hardinge evidently thinks that 'persuit' is a correct spelling, and that Mr. Brown made a foolish error in writing 'pursue.' It is fair therefore to let the corrector be corrected. 'Preventative' is also a common error for 'preventive.' Stick to tube-mills, Mr. Hardinge, and don't bother about spelling. However, on tube-mills Mr. Hardinge goes strong, and we are glad to publish his letter, together with the note on launder-bottoms. We add a replica of the drawings accompanying the U. S. patent, No. 864,357, granted to Mr. Brown, which is interesting in view of these letters from Messrs. West and Hardinge. The pleasant controversy over this rib-lining is only another exemplification of the fact that the best proof of the value of an invention is



Lining for Grinding Mills. Patented by J. R. Brown.

the simultaneous discovery of it by several men independently.—EDITOR.]

Explosion Heard Afar.

The Editor:

Sir—It may possibly be of some interest to your readers to know that the explosion at the Judson packing-house that occurred on February 20 was not only felt, but heard, in this neighborhood, at a distance of approximately 105 miles. It was noticed at about 4:10, and was strong enough to lead some of our neighbors to believe that our magazine had blown up, the houses being shaken to some extent.

C. H. WILDMAN.

Grizzly Flats, El Dorado county, California, February 25.

VARIATIONS IN MINING COSTS.

Written for the MINING AND SCIENTIFIC PRESS
By JOHN B. HASTINGS.

Referring to Mr. Finlay's article in the PRESS of January 4, on the above subject, I should say, as suggested therein, that the engineers and managers, collectively doing the important mining business of the country, are not weak on the questions brought up, that their estimates of future operating expenses are fairly correct, and that the unwarranted assumptions as to the low costs of mining are made by men who do not analyze the subject, either from self-interest or lack of training.

Looking backward at the end of a period, the amount of money spent, less a proper construction and possible development fund to be wiped out in the future, should represent the cost of mining; however, in estimating future operating expenses of a new mine, it would be unwise for an engineer to antieipate anything except depreciation of the equipment he thinks necessary for the mine. Very often, perhaps usually, such equipment, with allowanee for usual wear and tear, will last to the end, that is, the end he can see, on whieh the mine is bought. Taking the Bunker Hill case, it would not have done to forecast an unitemized, unknown, expenditure of $3,400,000 in first estimate of working eosts. I don't know what the amount was spent for, but it should have taken care of itself; the original estimates of mining and milling instead of $3.30 per ton as they have turned out, were perhaps $6.60. The Anaeonda aeeount is probably the greatest example of a tremendous outlay for plant above any antieipated value, or its present actual one; and yet divide the life of the mine fairly into periods, and the diffcrence between the costs attained with new expenditures, and the estimated costs for the same period, based on the former going charges, probably paid for the improvements. This is the history of large suceessful mines; sueh additional improvements, besides returning their cost, usually leave appropriate balances to the good.

As Mr. Finlay thinks there is no blanket law to cover every case, the way I try to arrive at proper estimates is by taking pen and paper, beginning at the bottom and working to the top. Below are some of the problems and conclusions:

Given a mine iu northern Mexico, 50 miles from the railroad, with hard quartz vein dipping 56°, and walls that will stand indefinitely, water for milling purposes to be pumped four miles under 1050-ft. head, and an effeetive 400 hp. steam-plant eight miles away, at wood and water, the power to be transmitted to mine, mill, and pumping plant by electrieity. Mill is at mine. The ore above and below main adit as specified below.

Cost of mining. This is subdivided into two aeeounts: First, that of actual stoping, and this is all that is to be charged against the ore estimated to be in reserve above the main adit. Second, the actual development of the ore before stoping. A charge for this, for instanee, is made on the ore estimated to be in reserve for 100 ft. below the adit. As a basis of any sueh eosts it is necessary to assume a steady production, in this case, the anticipation is 55,000 tons annually, and sufficient development to place that amount in reserve as extracted. The width of the ore being only 7.5 ft., it can be mined without timbers, or such a small amount that the cost need not be predicted. I assume that small air-drills will be used in stopes, large ones in the shaft, and that levels and raises will be driven by contraet Mexican labor. To obviate excessive expense for power, stoping and hoisting must be done in the day-time. The present wage scale for Mexican miners is $1.50 per diem, the scale presented is $1.75, except in the case of machine-men who are put at $2.50 per diem, a high class (Mexican) man is needed on machines.

ESTIMATED DAILY COST OF STOPING 55,000 TONS YEARLY.

18 Miners in stopes	$ 45.00
5 Muckers and assistants in stopes	8.75
5 Trammers on levels	8.75
3 Trammers on surface, 500 ft. to mill	5.25
1 Shift-boss	3.00
Powder, fuse, and lights	15.00
½ Supplies, power, and administration	80.00
Total cost of stoping, daily	$165.75
Cost per ton (perhaps 10c. per ton too much for ore above adit)	$1.10

ESTIMATED DAILY COST OF SUPPLIES, ADMINISTRATION, AND POWER AT MINE, TO BE DIVIDED EQUALLY BETWEEN STOPING AND DEVELOPING.

3 Timbermen and carpenters	$ 7.50
1 Skip-tender	3.50
1 Powderman and storekeeper	1.75
1 Timekeeper	2.50
2 Blacksmiths	10.00
2 Helpers	4.00
1 Hoist-engineer	5.00
3 Engineers for compressor	7.50
½ Master mechanic	4.00
1 Assistant mechanic	2.50
½ Electrician	2.50
1 Foreman	6.00
Supplies, such as rails, cars, rope, drills, hose, pipe, timbers, nails, coal, lubricants, etc., at mine	35.00
1½ Engineers at power-plant	7.50
1½ Firemen	3.00
1 Yard-man	1.50
10 Cords of wood	20.00
½ Clerk	2.50
½ Book-keeper	3.00
½ Stenographer	2.00
1 Surveyor	5.00
½ Policing	4.00
½ Horses and teamster	3.00
1 Watchman	1.75
½ Management	10.00
½ General expense	5.00
Total daily costs, supplies, administration and power	$160.00
½ Apportioned to stoping	80.00
½ Apportioned to ore development	80.00

POWER PLANT.

1½ Engineers	$ 7.50
1½ Firemen	3.00
1 Yardman	1.50
15 Cords of wood	30.00
Oil, lights, and supplies	6.00

MAIN PUMPING PLANT.

1 Engineer	5.00

GENERAL OFFICE.

½ Clerk	2.50
½ Bookkeeper	3.00
½ Stenographer	2.00
½ Policing	4.00
½ Horses and teamster	3.00
½ Management	10.00
½ General expense	5.00
Total daily cost of milling and cyaniding	$256.16
Cost per ton at 55,000 tons per annum	$ 1.70

ESTIMATED DAILY COST TO PLACE IN SIGHT 55,000 TONS OF ORE YEARLY.

Sinking main shaft 321 ft. per annum, at $40 per ft.	$ 35.18
Driving 1800 ft. of levels and cross-cuts, at $6 per ft.	29.59
Nine raises, each 120 ft. high, at $9 per ft.	26.63
2 Carmen on surface (underground carmen are already included in shaft, level, and raise costs)	3.50
Explosives and lights	20.10
⅓ Supplies, power, and administration of mine	80.00
Total daily cost of development	$195.00
At 55,000 tons yearly, cost per ton	$ 1.30
Cost per ton of stoping as found above	1.10
Total cost of stoping and development, per ton	$ 2.40

ESTIMATED COST, DAILY PER TON, OF MILLING AND CYANIDING IN A PLANT TREATING 55,000 TONS ANNUALLY AT 80 MESH.

1 Head millman	$ 8.00
1 Night cyanide man	5.00
½ Electrician	2.50
½ Master mechanic	4.00
3 Engineers	12.00
3 Battery-men	15.00
3 Assistant battery-men	5.25
6 Mexicans in cyanide plant	10.50
3 Men for tube-mill	5.25
1 Assayer	5.00
1 Swamper	1.75
1 Yardman	1.75
Cyanide, 275 lb., more or less	55.00
Lime, 2700 lb., more or less	20.25
Oil and lights	4.00
General supplies and expense	18.41
Total daily expense in the mill proper	$173.66

RECAPITULATION.

Cost of mining ore developed above main adit	$ 1.10
Cost of developing ore below main adit	1.30
Cost of mining ore below main adit	1.10
Cost of milling and cyaniding	1.70

Exclusive of taxes and other office expense or management save at mine and mill.

REQUIRED HORSEPOWER.

This might decide the site chosen for the power plant and mill. The amount depends primarily on the anticipated product of the mine—placed at 55,000 tons annually. For this production the items are about as follows:

	Hp.
Self-dumping skips, holding 1.5 tons, weighing themselves one ton, and rope weighing 0.5 ton, total weight 3 tons, running balanced	75
Bucket sinking-hoist	15
Station-pump	10
40 Stamps of 1050 lb. each, or their heavier equivalent	85
10 by 20 in. crusher	25
Compressor (air for drills and sinking-pump)	75
Agitation, there will always be 300 tons of sand and slime in the mill, at 48-hr. treatment	90
Tube-mill plant	35
Blaisdell excavator	10
Pumping at mill, 150,000 gal. 200—250-ft. lift, 210 gal. per min. for 12 hr.	25
Pumping from main pumping station, 105 gal. per min. for 12 hr., about 1150 ft. lift	60
Maximum power required	505

The estimate of water from pumping station is based on a daily usage of 225,000 gal., and one-third loss, besides which the mine may supply a small amount. By not running the main hoist, and two-thirds of the compressor capacity at night, a saving of 125 hp., the power required at night would be 380 hp. By pumping from the main station, and about the mill at night, and using the excavator and crusher only at night, equal to 120 hp., the power required in day-time would be 385 hp. An auxiliary object in thus averaging the use of power is to bring the amount within the limit of an available hydro-electric power.

Are the above costs whittled down too closely?

It is neeessary for an engineer to guess at the future of a mine, whether the ore will stop at the 500-ft. level as at Bodie (described by R. Gilman Brown in the *Trans* A. I. M. E.), or go down ten times that depth, as at the North Star in Grass Valley. The desirability of investment will probably be founded on the answer to the questions: How long will the mine last? How much will the future ores pay?

Suppose the mine and plant just described cost $1,200,000. This money is worth at least 6% as soon as invested, allow this interest to begin on completion of the mill, and that, as usual, an extraordinarily good run can be made the first year. At the end of the year the account stands as follows:

$1,200,000 and 6% for first year	$1,272,000
Net profit on 55,000 tons at end of first year	450,000
Balance due on investment at end of first year	$ 822,000
$822,000 and 6% for second year	$ 871,000
Net profit on 55,000 tons at end of second year	250,000
Balance due on investment at end of second year	$ 621,000
$621,000 and 6% for third year	$ 658,000
Net profits on 55,000 tons at end of third year	250,000
Balance due on investment at end of third year	$ 408,000
$408,000 and 6% for fourth year	$ 432,000
Net profit on 55,000 tons at end of fourth year	250,000
Balance due on investment at end of fourth year	$ 182,000

So that at the end of 5 years the purchaser has received his principal and 6% interest, and owns the mine and mill, as well as the tailing dump. What will they be worth? What is he entitled to? Some people have high expectations of mining investments, they have even been led to expect them by vendors. If he should want to double his money, it would take nearly another 5 years. Is this too much profit to hope for at the end of ten years of mining, is it too much to expect of another business? The fact that the mill might be warmed up on low-grade ore for a period is omitted as unessential.

Sometimes the problem is not sufficiently solved or does not call for such close figures as above; or the method of treatment advised and costs assumed are tentative, as in the following case where the

writer wished finally to consult the best metallurgists (as he would advise in every reduction case):

Given a second mine, ten miles from a branch railroad in southern California, with plenty of water, and wood at $5 per cord, but coal and coke pretty high.

A body of ore, two-thirds oxide and one-third sulphide, the former containing say 0.3 oz. gold, 6 oz. silver, 0.5% copper, 57% silica, 17% iron, 4% sulphur, 4% alumina, 2% lead, and the latter containing 0.1 oz. gold, 2.0 oz. silver, 1.2% copper, 10% silica, 33% iron, 37% sulphur, 0.5% alumina.

The mining of this soft ore through a 'glory hole' will only cost 50c. per ton; the cost of future development is entirely unknown, as it is a case of looking for another orebody. Here the engineer must make up his mind what the prospecting value of the mine is, as an empty shell, after the ore in reserve is extracted.

As the oxide when mined breaks as fine as a concentrate, and wood (wood preferably) and oil are comparatively cheaper than coke, would it be advisable to smelt such ores in reverberatory furnaces, treating 300 tons daily? Could it be done for $4.50 per ton, including all proportionate expenses on the ground and marketing of product, but not losses or deductions? And what would the losses be? Wages, $3 to $4 per diem: freights high; lime, $5 per ton.

Take a third mine in Mexico, 50 miles from the railroad, with labor at 50c. per diem, and Mexican and American mechanics from $1 to $5 per diem.

Given a compact hard pyrite ore, 15 ft. wide, and a long shoot, with smooth hard walls, dipping 65°, a homogeneous ore easily broken, containing 35% iron, 40% sulphur, 12% silica, 5% alumina; which evidently makes about 80% straight pyrite, or 9 cu. ft. per ton, allowing imported drillers to make on contract $4.50 per eight-hour shift, this ore as developed above adits should be delivered to the mouth of the mine for $1.25 per ton, including all expenses at the mine. Timbers 15c. per linear foot, but scarce.

With the following tenor for the ore: 0.15 oz. gold, 8.6 oz. silver, 2.5% copper, and analysis as just stated, with silver at 60c. per oz., and copper at 16c. per lb., treating 300 tons daily, with an admixture of 150 tons of matte, silica, and lime, which pay their own way, the following is estimate of costs and losses:

Labor, management, and general expense	$ 300
Power; 20 cords of oak	60
Tools, repairs, chemicals, etc.	50
11% coke; 50 tons at $30	1500
Total daily costs, 450 tons	$1910
Cost per ton	$4.25
Silver. Loss in smelting	$0.15
Silver. 5% off in N. Y. on $5 left	0.25
Gold. Loss in smelting	0.10
Copper. Loss in smelting, 5 lb. at 16c (leaving 45 lb)	0.80
Copper. Cost of marketing in N. Y., 45 lb. at 2½c	1.13
Freight on 50% matte at $30 per ton from mine to N. Y., 3c. per lb. on 45 lb. copper per ton of ore	1.35
Freight. Proportionate deduction per ton of ore on 1.3% off copper matte	0.19
Total cost and loss per ton of ore	$8.22

How about these smelting costs, the losses in silver, gold, and copper, the percentage of coke, the final grade of matte, and the marketing charges, and adoption of straight pyritic smelting?

Take a fourth mine on the southern Alaskan coast, a mile from the ocean and 700 ft. above it, with mild climate. Plenty of timber and water. A nearly vertical orebody, 20 ft. wide, 150 ft. long, of magnetite, carrying chalcopyrite and pyrite, with 0.4 oz. gold, 1.0 oz. silver, 2.5% copper, 47% iron, 8% sulphur, 15% silica, 5% alumina, 5% magnesia, 2% lime. From this analysis of samples obtained by blasting holes 10 in. deep, and 2 ft. apart, in all about 30 tons, and the compact nature of the ore, it apparently only takes 7 cu. ft. to make a ton. The orebody is not sufficiently developed to warrant a statement of large tonnage, but assuming it to go a moderate depth further so that it would aggregate 55,000 tons, then the further development cost on contract would be: An adit 360 ft. long at $4320; a sill-level 150 ft. long, 20 ft. wide at $4500; three raises 10 ft. high at $500; and another connecting raise 35 ft. high, to bottom of winze present, at $500; a total with extraneous costs of $10,500; or 20c. per ton for completed development.

The itemized costs of mining 250 tons daily of such a body from above adit-level and delivery with an aerial tram, a mile long and 700-ft. fall, in connection with the development and working of other mines would be:

Two compressor engineers	$ 8.00
Blacksmith and helper	7.50
Day and night foreman	11.00
Machinist	5.00
15 Machine-men at $4.50	67.50
15 Machine-men at $3.50	52.50
6 Carmen	21.00
Powder-monkey	4.00
Powder-man and roustabout	6.00
2 Timber-men	7.50
Timber	12.50
Blacksmith coal	1.50
Powder and fuse	25.00
Candles	5.00
Lubricants	1.50
Steam-coal, 6 tons	36.00
Steel and drill-parts	10.00
Sixteen assays	4.00
Tramway and general expense	39.50
Total cost of mining	$325.00
Additional development	50.00
Total cost	$375.00
Cost per ton	$1.50

The system of mining calls for a sill-level the full length and width of the ore; one through raise for air, lowering timbers, or waste, if necessary; three raises through first ten feet of pillar left above sill-level by which the ore will be drawn off as broken, and the pillar itself afterward drawn out. A sufficient allowance is made for timber-men, timbers, etc., to meet any emergency of soft walls and occasional sorting. Machines will work two shifts and all holes be loaded and fired by powder-monkey. Machine-men would work on contract per foot of hole drilled, hiring their own runners, this is on basis of

using 3¼-in. drills; a large number of smaller drills could be used, it is a question of trial and efficiency.

The costs and losses in smelting 250 tons of this ore daily, together with 100 tons of suitable silica-lime copper ores that will pay their way and stand their proportional loss, making 350 tons daily, and producing 45% matte, with silver at 60c. per oz. and copper at 16c. per lb., is as follows:

General labor, 50 men	$200.00
Administration and general expense	100.00
Coke, 13%, 45.5 tons, at $7.50	337.50
Steaming coal, 10 tons, at $5	50.00
Tools, chemicals, and repairs	37.50
Total daily expense for 350 tons	$735.00
Direct smelting expense, per ton	$ 2.10
Silver. Loss in smelting	0.10
Silver. 5% off in N. Y. on 50c. left	0.03
Gold. Loss in smelting	0.10
Copper. Loss in smelting, 8 lb. at 16c. (leaving 42 lb.)	1.28
Copper. Cost of marketing 42 lb. at 3c	1.26
Freight on 45% matte at $5 per ton to coast points, ¼c. per lb. on 42 lb. copper, per ton of ore	0.10
Proportionate deduction per ton of ore on 1.3% off copper matte	0.19
Total costs and loss per ton of ore	$ 5.16

Depreciation on a plant of this kind would be 20c. per ton.

The fifth and last mine is again in Mexico, on the railroad, with wages from 75c. per diem upward. The ore is a solid pyrite containing 3.2 oz. silver, 0.05 oz. gold, 1.6% copper, 40% iron, 38% sulphur, 11% silica, and about 1% each of zinc, arsenic, manganese, lime, and alumina. Plenty of wood and water, and abundant hydro-electric power. Smelting daily 1000 tons of ore, with 500 tons of mixed matte, silicious, and lime ores, the latter paying their way and supplying their slag-losses; with silver at 60c. per oz. and copper at 16c. per lb.; costs and losses are estimated as follows:

Labor, 150 men, Americans and Mexicans	$ 300
Administration	75
Tools, chemicals, and repairs	100
Coke, 3%, 45 tons, at $15	675
Hot blast, 15 tons coal	75
Unforeseen expenses and alterations	200
Converting	205
Total daily costs on 1500 tons	$1630
Direct smelting expense, per ton of blister copper	$1.09
Silver. Loss in smelting	0.12
Silver. 5% off in N. Y. on the $1.80 left	0.09
Gold. Loss in smelting	0.10
Copper. Loss in smelting, 8 lb. at 16c. (24 lb. left)	1.28
N. Y. charge for refining blister copper, at $20 per ton, cost per ton of ore	0.25
Total costs and losses per ton of ore	$3.12

Must these items be added to or decreased, are some too high and others too low? It may give interest to these statements to add that four of these five problems are yet unsolved, lying dormant.

Mr. Finlay has well illustrated the difference in total costs between Cripple Creek and Tennessee. The discrepancy is, firstly, between mining scattered bodies of narrow high-grade gold ore and large bodies of low-grade copper ore; secondly, between the average output of a total mining district, an aggregation of all kinds of mines, and one essentially good one; thirdly, between results obtained under the direction of a miscellaneous mass of people and that of one of the most capable of mining engineers.

The cost of the total output of a mining district can never be applied to an individual mine, not even on the Rand or at Leadville, the two areas where work has been peculiarly confined by geological boundaries. In conclusion, I wish to sign a 'round robin' of thanks to Mr. Finlay for the table of working costs compiled by him and appearing in his valuable article.

Coal Consumption.—The records of the great Cunard Atlantic liners, the *Lusitania* and the *Mauretania*, are watched with augmented interest as time passes. It is not denied that the coal consumption is about 1000 tons every 24 hours. It may be a little less or a little more. The bunkers hold 7000 tons. How much remains in them at the end of each trip is only known by a select few. We take it for granted, however, that each ship burns 1000 tons of coal every 24 hours—that is to say, the contents of the trucks of two 50-car coal trains, one train for the day and the other for the night. As there are 25 boilers, each boiler must take 20 tons per day and the same every night. It may be assumed that, the boilers being Howdenised and the coal good, each pound of coal will make 9 lb. steam; that is to say, no less than 9000 tons of steam are made every 24 hours, or, neglecting fractions, 375 tons of steam pass per hour through the engines. As the pressure is about 200 lb. absolute, each pound of steam will occupy 2 cu. ft., which means that 1,680,000 cu. ft. of steam passes through the engines every hour. These are large quantities, but they shrink when compared with the flow of water through the condensers. That will be about 50 times the weight of the feed water, or $50 \times 9000 = 450{,}000$ tons per 24 hours, or 312 tons of water every minute, or 100,800,000 gal. per day. To realize what this means, it will suffice, perhaps, to say that the quantity would represent the water supply at 35 gal. per head per day of a city with nearly 3,000,000 inhabitants, or almost enough for the city of Paris. Turning to the furnaces, we have equally astounding figures. Allowing 20 lb. of air per pound of coal, we have 20,000 tons of air passing through the grate-bars every day. Taking the temperature of the supply at 100°, we have 14 cu. ft. air per pound, so that 26,100,000 cu. ft. air enter the furnaces every hour. A pipe 10 ft. square would pass this quantity if the speed were that of a great gale—50 miles an hour.—*The Engineer.*

Montgomery county, in North Carolina, has a gold mine, named the Iola, which produces steadily about $120,000 per annum, on a capitalization of $500,000. The stock is all held locally and is not subject to hippodroming. The mine was a bare prospect and was developed by a local prospector, who still holds the control and has built a 50-mile standard gauge railroad out of the profits.

NOTES ON RAWHIDE, NEVADA.

Being an Excerpt From the Letter of One Mine-Operator to Another.

The formation is eruptive and the three porphyries, rhyolite, dacite, and andesite, are found in the district. I think the rocks occur as flows. The most important of the three is rhyolite, next the andesite, and lastly the dacite. The dacite, without doubt, occurs in necks similar to those of Tonopah. The rocks are all altered and silicified, and probably much faulted. A more careful study than I gave the camp is neeessary to determine these features.

The important strikes are on three low hills, really one north and south ridge cut into three small hills by erosion. The first to the north is Grutt hill, the second Balloon hill, and the third Murray hill.

Grutt hill more than others shows a great shattering due to cooling from a molten mass. The contraction joints are so numerous that, when cemented by quartz, a piece of rock will have as many seams of quartz as a piece of quarter-sawed oak will have markings. This quartz was probably deposited from heated ascending silicious waters. The quartz is a chalcedony and is, I think, usually barren. Occasionally a better character of quartz is found and with it some free gold; in fact, quite a few fair free-gold specimens have been taken from Grutt hill. However, with all their talk, I cannot find that a shipment has ever been made from this wonderful hill. There is nothing that can be called a fissure, nor any body of ore that in any way approaches a vein. Such workings as the hill affords, show no definition or walls. I rather think most of the shafts have been sunk at places where a few specimens have been found; these occur always in the irregular 'seams,' as they are called. They are not 'seams,' but I know of no better word. They are narrow, as a rule, and the widest is seldom more than a half-inch wide. The ore does not even follow a zone of fracture, shear zone, brecciated zone, or crushed zone. The whole hill of some 60 or more acres is of about the same character as far as the seams go. I can account for it in no other way than that the whole hill was infinitely cracked in cooling and the little cracks cemented with silica. These seams are very numerous, but those carrying gold are not numerous enough, in my opinion, to make the whole mass even a low-grade ore.

There are probably some half dozen shafts on this hill. Most of them are the work of lessees. Their 'ore,' as they call it, is thrown over the dump like waste, and it resembles waste, regardless of the claim being made that it is all mill-ore. It is mostly altered rhyolite and shows a little iron stain. The lessees all say that they "will cross-cut at the 50-ft. level," as they left the vein at some point higher up in the shaft. Most of these leases are for sale, and one must expect a strong statement from the owners, and generally gets it. I saw some twenty or thirty sacks of ore on the hill, but no claims are made that any has ever been shipped. I am told that a few sacks running from $1000 to $3000 have been shipped. This arises from the fact that many specimens have been found on the hill.

As an example of the foundation for stories such as you are reading daily: On Grutt hill about February 1, quite a few little seams were observed. After cleaning off the surface, this strike was left for ten days, and was daily visited by hundreds, if not thousands. When it got stale as a star attraction of this kind, a few holes were placed and the mass blown out. It is said some seven sacks of $3000 each were recovered. A piece was thrown through a bank window, and was accepted for the price of the glass and put on deposit for the orphan fund. These kind of yarns, when well circulated, are largely responsible for the 3000 people that now inhabit the camp. I was not present at the great blast, but arrived the next day. I visited the hole from which this $21,000 came and found it about 6 ft. long, 3 ft. wide, and about 18 in. deep. I saw no signs of a continuation of the ore, or any ore at all in the side, ends, or bottom. This will give an idea how completely these seams can be dug out and how they lack continuity. Holes may be found within ten feet of one another, and yet no connection can be observed between one and the other.

The lessees on Grutt hill are working most indifferently—none of that snap that was found at Tonopah and Goldfield. On one lease some 20 sacks are piled, and at two other places from five to ten sacks. These have been on the ground for several months. One lessee claimed $12,000 per ton for his six sacks—but no care was taken to prevent theft! This is a sample of the 'dope' that is handed out.

Balloon hill is somewhat different, in that the mineralization seems to follow incipient fissures in the rhyolite. There is but little silicification, and pieces of much altered rhyolite, called locally 'talc,' will be found at times to run very high. In this respect this hill much resembles the Bullfrog district, much of the high-grade stuff being a marker for the ore of the Montgomery-Shoshone. The two principal leases on this hill are the Kearns No. 1 and No. 2. The No. 1 is said to have shipped 23 tons of ore to Goldfield that assayed $44.80 per ton. Some 120 tons of ore are now sacked on the dump. At the time of my visit all the material that came from the shaft went over the dump. It looked like country rock, some pieces being more silicified than others. Great claims are made for this and the No. 2 lease, but I saw no ore being sacked on either. At best they can be only fair mill propositions, in my opinion. What gives the values are the talc seams, and the gold in these is secondary and as fine as flour. It is not uncommon to see very rich hornings on any and all of the principal leases. When one knows the streaks and seams, the richest kind of rock is readily found for the visitor. Many a visitor leaves the camp with most glowing yarns of the hornings that have been made for him.

I was not permitted to sample anything, in fact, did not go that thoroughly into the camp. Prices for both mining ground and real estate were so high and the tone of the camp so uncertain, that it

did not appeal to me as a camp that would win out. In this way I may be wrong, as these desert porphyry camps have proved surprises only too frequently. The heart of the camp, say about 60 claims, is owned by three outfits—the Grutt Bros., King of Montana, and the Van Dorn's.

The only working of any consequence on Murray hill is the Murray lease, incorporated under the name of the Rawhide Mining & Reduction Co. There seems to be more of a vein here than on any of the above mentioned leases. A shaft has been sunk some 75 ft. and a few sacks of ore were to be seen on the dump. Mr. Murray told me that he had sampled 350 ft. of vein and had secured an average of $79.80 per ton in gold. Stock is to be had, I think, at 25 cents. In fact, every lease or hole in the ground is incorporated or in the process, and it is readily apparent why such statements issue. I noticed that all ore went over the dump with the usual carelessness; it is probably not very high-grade.

The Miller lease is located on Hooligan hill. The shaft is about 60 ft. deep and considerable drifting has been done. No high-grade is claimed, but I was told the whole width of country rock, called a vein, assayed 16 oz. gold. This is pretty high-grade ore to throw over the dump. This lease, I understand, is incorporated and the stock held in Chicago. There are seams that will pan well, but I am very much of the opinion that the general run is low. I saw nothing that I would call a vein. The formation at this point is, I think, a dacite and is quite strongly fissured; most of these fissures are open and in many places one can shove his hand in. The shaft has been sunk on one of these and it is called a hanging wall. I saw no silicification or even crushing along this fissure or zone, so I could hardly call it a vein. There are little oxide of iron seams that will pan very well. At a certain place on the dump good pannings are found, but whether the whole dump will do as well, I am unable to say.

Well, there are many other points of interest about the camp, but they are about like those enumerated. in fact, the ones mentioned are the best. Now, I cannot see that Rawhide has developed a great quantity of even milling ore. The obscure occurrence of the ore has made it difficult to find and more difficult to follow it. Still we have all grown to think that anything is possible in these porphyry formations, after the history of Goldfield. I think it well to keep an eye on the camp, but at present I could not recommend either mining or real estate investments. I had an eye only to the speculative side of the camp, and intended to invest only upon finding a camp of undoubted merit. I think conditions poor for promotion, and the camp did not look good enough to take a chance at their prices.

There will, in my opinion, be a great reaction from the present boom, as there are now some 4000 people in the camp and probably not more than 500 are given a living. The rest are hangers-on or prospectors and lessees. This condition cannot last, and undoubtedly the great number of unemployed left in various busted camps round about, made it possible for Rawhide to have a population today of 4000. The camp does not justify a population of more than a few hundred, as there are but 50 men working on the mines for wages. The wages are high and have attracted a great many idle miners from other camps, like Goldfield and Tonopah.

While I have not a great deal of confidence in Rawhide, I will keep an eye on the camp. If I get any really reliable information I may make another visit in there during the next month or two. At that time I expect to see prices much lower for mining ground. But it is not unlikely that by that time at least 100 mining companies will have been incorporated, and in that event it will be hard to get in on the ground.

To sum it all up: There is at present no quantity of high-grade ore opened up in the camp; this is evident, for they are not sacking and shipping, and there are at least 75 teams going back empty to the railroad and willing to haul ore for $5; there is not a true well defined vein in the camp, outside of the Royal and Tiger, some two miles west of the town. As a milling proposition, the conditions are bad because there is no water within 9 miles and no fuel within 35 miles. The camp will have to have a railroad, and to get this they must show up a large amount of ore. The little mills that are talked of now will never pay much better than shipping. It is very difficult to get any reliable information, and knowing that there is a great deal of fake handed out, one is too suspicious to believe any stranger. To sample the camp independently is unallowable, so that general impressions are all that most leave the camp with. To me there is not the right tone about things and there is too much insincerity about the whole place. But keep an eye on the place: it may have some surprises.

U. S. Geological Survey.—A report on the Park City district, Utah, is in course of preparation by J. M. Boutwell, who has recently returned to Washington from a thorough inspection of this district. Last year Mr. Boutwell had the charge of the statistical work of the Survey on the production of zinc, lead, and quicksilver in the United States; but he is now devoting his entire attention to mining geology. C. E. Siebenthal has taken up Mr. Boutwell's work in zinc and lead, and the subject of quicksilver has been assigned to W. D. McCaskey. Mr. Siebenthal is also gathering statistics of general mine products in the Mississippi Valley. By direction of the Secretary of the Interior, James H. Gardner is making a classification of the government coal lands in the Carthage district, Socorro county, New Mexico, which will be followed by their valuation and restoration to public entry. Mr. Gardner has been at work in the Carthage district nearly a month. Waldemar Lindgren left Washington on March 15 to gather geological and statistical information in California, Nevada, and Utah. Mr. Lindgren is in charge of the work of the Survey on metalliferous mineral deposits of the United States. His trip will consume about a month. The Survey investigation of the copper deposits of Shasta county, California, has recently been completed by L. C. Graton. Mr. Graton is now in Washington working on his report in this connection.

CYANIDATION OF SILVER ORE IN MEXICO.—I.

By W. A. CALDECOTT.

*The remarkable advance during the last few years in the treatment of silver ore in Mexico may be very largely attributed to the replacement of the old and costly patio process by cyanide treatment preceded by very fine crushing, to railway development and to water-power installations, which provide electric power cheaply for remote mines, where the cost of fuel would be prohibitive. Power is now being transmitted up to 170 miles, and supplied at 30 s. per horse-power per month, or considerably less than the average cost of electric power on the Rand.

The patio process, invented at Pachuca by Bartolomé de Medina in 1557, nearly a century before Van Riebeck landed at the Cape, is still in operation at the same mine in that district, but is now mainly of historical interest. The wretched condition of the mules at present employed in working it, in place of the men who used to tread the *torta*, makes its disappearance less regrettable than if animals had been replaced by the efficient mechanical digging appliances which have been invented for the purpose. The process of cyanide leaching preceded by a chloridizing roast is also now a thing of the past, and much of the same applies to hyposulphite lixiviation.

The pioneer work of our past president, Charles Butters, is indissolubly associated with the advance in Mexican cyaniding and fine-grinding practice, while the El Oro company is famous throughout the mining world for its enterprise in developing metallurgical methods. But apart from these well known names, the results of the skill and energy of our fellow-workers in charge of various ore-reduction plants are obvious in every mining district. While these last are without the great advantages of the cumulative experience and resources of the group organization, this is in some measure offset by the judicious foresight of individual companies in providing means for carrying on extensive experimental work, and also adequate plants for handling the ore under routine working conditions.

The attitude of the Mexican Government under the firm rule of that remarkable man, Porfirio Diaz, is distinctly favorable to the investment of foreign capital in mining and other industrial enterprises. It is to be regretted, however, that in spite of the many opportunities which the application of modern methods in Mexico offer, the amount of British capital now invested there is proportionately far less than was the case some eighty years ago, in the days of the United Mexican Company.[1]

Unskilled labor is cheap, costing in all about 1s. 6d. per day, but this advantage is somewhat offset by its irregularity, owing to the occurrence of the numerous church *fiestas*. The natural hereditary tendency of the Mexican laborer, or *peon*, to steal all he can, is counteracted by a regular system of special clothing for work in the extractor-houses, supplemented by watchmen and electric alarms. Shrines and bull-rings to suit the tastes of workmen appear to be almost regular items in a mining company's equipment, and some knowledge of Spanish is a necessity for those engaged in mining work. In the City of Mexico an electrolytic refinery for gold and silver bullion was started in 1906 by a private company, whose enterprise in this respect is significant. The metric system is generally used in dealing with Mexican silver ores. Thus cyanide consumption is expressed in kilograms per metric ton of 1000 kg., or 2204 lb., and silver or gold are reported in grams per metric ton. Conversion, however, is readily accomplished by taking 1 gm. per metric ton as equal to 14 grains per 2000-lb. ton, and 1 kg. per metric ton as equal to 2 lb. per 2000-lb. ton. Mexican currency is practically equivalent to one half the value of corresponding U. S. coins. Hence the *peso*, or Mexican dollar, is worth about 25 pence, or 0.5 dwt. gold.[2] The fluctuating value of silver, however, introduces a disturbing factor in mining operations with which we are happily unfamiliar here; the result of a 10% depreciation in the silver market may best be realized when the effect is considered of a possible 10% drop in the percentage recovery of gold from banket ore.

The average Mexican silver ore is usually a hard flinty quartz containing little extraneous base metal mineral.[3] The bulk of the silver exists in the form of sulphide, associated at times with a little arsenic or antimony, while occasionally silver chloride and native silver occur. A small percentage of gold is found with the silver and constitutes a considerable proportion of the bullion value, since with silver at 2s. 6d. per oz., gold is worth 34 times as much as silver. As a rule the gold is extracted during cyanide treatment a good deal more readily than the silver, so that special attention during treatment is not paid to it. Manganese is occasionally found associated with silver ore, and is reported to exercise a detrimental effect on the extraction.

The essential features of present-day treatment of silver ore in Mexico consist in very fine crushing with cyanide solution, treating the bulk of the resultant pulp as a slime by decantation, followed by mechanical filtering and zinc-shaving precipitation of the solution. While the foregoing broad statement may be taken as correct, there exists, as is naturally the case with a progressive art, a considerable diversity of opinion among competent operators as to the advisability of many details of practice, and hence the following more detailed descriptions must not be considered as universally applicable.

The fine state of division and uniform distribution of the precious metals in the ore render finer crushing necessary than in common practice on the Rand, but the means adopted for this purpose naturally vary with the existing equipment of mills and with the views of those in charge. Generally speaking, stamps followed by tube-mills represent the most advanced practice, but at a Guanajuato plant stamp-milling alone with slotted screening equivalent to a wire-woven screen of 45 mesh serves to convert the bulk of the ore into slime, though at

*Abstracted from *The Journal* of the Chemical, Metallurgical & Mining Society of South Africa, January, 1908.

the cost of the low duty of 2.7 tons per stamp per 24 hours. At a Pachuca plant, stamps, followed by Chilean mills crushing through 80 mesh, are used and yield much the same resultant pulp.

The most notable and up-to-date plant, however, is the Mexico mill of the El Oro company, which has 40 stamps and six 4 by 20 ft. tube-mills to reduce with 16-mesh battery screening 200 tons of hard flinty ore per day to a product of which 90% passes 200 mesh. Taking each tube-mill as equal to 20 stamps in crushing capacity, this equipment, with five tube-mills running, virtually means a stamp-duty of about 1½ tons of ore per 24 hours. This mill, which has only lately started, should throw much light on the debated question as to whether under such conditions all-sliming yields more profit than the present usual production of 50 to 75% slime, with the balance of the pulp as specially hard and tough fine sand requiring treatment by leaching. Should it be possible in the future to secure as rapid dissolving of the metal in the sand as of that in the slime, it is probable that the next operation of separation of solution and solid in these two products will be carried out in the same way as, for example, by horizontal mechanical filters. As is realized here, the question of the actual cost of all-sliming is of great importance in view of the simplicity and other obvious attractions of the method.[4] Other points of interest at El Oro are the satisfactory use of separate iron guides instead of wooden battery guides, and of concrete mortar-blocks. Trials are now proceeding in stamp-milling without battery-screening, but with a high slot discharge on the lines of the old German schubersatz.[5] As at the Homestake in South Dakota, a foundry is run by the El Oro company, and also a small blast-furnace for periodically working up slag and other by-products, both of which prove of great service. The corrugated cast-iron tube-mill lining block is employed, and is claimed to give treble the life of plain iron liners.

Amalgamated copper plates are not generally used in Mexican reduction plants, but following the stamps, and sometimes the re-grinding appliances as well. Wilfley or other concentrators are employed to remove any metallic or granular particles of valuable mineral which would yield but a poor extraction in the sand-plant. The concentrate is usually shipped to a smelter, together with a certain amount of hand-picked rich ore.

The system of the secondary grinding circuit involving hydraulic classification of all final pulp, with which we are so familiar on the Rand, is not invariably used, and in general less attention seems to be paid to minimum water ratio in tube-milling, and to maximum practicable weight, drop, and speed of stamps than is considered advisable here.

Sand is commonly separated in vats from the pulp, leaving the battery by Butters distributors, and long sand-treatment is usual, while belt-transfer and Blaisdell excavators and aerators are likewise employed at some mills. When the fall and water available permit it, discharge of sand as well as slime residues by hydraulicking into the creek is practised, and this obvious advantage is little restricted by laws upon the fouling of streams.

In slime treatment, a notable feature is the lengthy agitation and aeration by means of ordinary stirring gear, which sometimes occupies in all 50 hours. This is rendered necessary by the slow rate of solution of the silver.[6] An ingenious system for the combined aeration and agitation of sand as well as slime, on the principle of a vertical Pohle air-lift pipe in the centre of a conical bottomed vat, 40 ft. high and 15 ft. diam., has been lately introduced at Pachuca from Australia.[7] In one or two old plants, with shallow rectangular sand-vats, converted into slime-vats, stirring and aeration are more or less imperfectly performed by means of a small pipe attached to an air-hose, which is plunged by hand below the surface of the pulp into different parts of the vat in turn.

When mechanical stirring-gear is used, settlement between the numerous decantations and agitations is not carried to completeness on account of the difficulty of starting stirring again, with the result that although as much as 10 tons of solution per ton of dry slime are decanted off for precipitation, washing is relatively imperfect, and the strong 0.1% solution frequently used in slime treatment causes a heavy mechanical loss of cyanide in the solution discharged with the residue. To reduce this loss, which may approach 2 lb. cyanide per ton of dry slime, as well as to improve the recovery of the silver and gold, mechanical filters to follow and supplement the decantation are coming into general use. The Butters[8] filter is most generally employed, though the Ridgeway,[9] Burt,[10] and others are now also being exploited. As elsewhere, clogging of filters in time with lime salts reduces their efficiency and necessitates periodical treatment of the cloths in a dilute hydrochloric acid bath.

In addition to the use of strong solution in slime treatment, a good deal of lead acetate[11] is added to the charge of slime-pulp, varying from 4 to 12 oz. per ton of dry slime. This is many times the amount of, say ½ oz. per ton, used here; and the apparent reason for the practice is discussed later in the second portion of this paper.

In precipitating practice, variations caused by differing conditions from gold-ore treatment are likewise noticeable. The strong solutions employed and the considerable weight of silver to be precipitated cause the employment of somewhat coarse zinc-shavings, for which a lead coating is not needed, as the zinc-silver couple soon formed has a high precipitating efficiency. As a rule, the extractor-boxes are placed several feet above the floor so that in cleaning up, the slime can be gravitated to a common sump which supplies the suction-hose of the filter-press pump. Simply passing through a fine screen of the zinc-box precipitate affords a product containing half its weight or more of bullion, which is briquetted by

air-pressure, after partly drying with hot air in the press or in a steam-heated pan, and is then smelted into a high-grade bullion without any acid treatment. As a plant may yield a ton of bullion in a month, a weekly clean-up is common practice, and large (No. 300) graphite crucibles or forged steel pots 1.5 in. thick are used. Furnaces using crude oil as fuel are in common use, and the El Oro company employs a neat quick-acting air-lift to lift crucibles from the furnace for pouring.

At present the total consumption of cyanide varies from 2 to 4 lb. per ton of ore, and the recovery from all sources of the silver in the ore from 70 to 90%, and of the gold appreciably more. As might be expected with very fine crushing, and heavy power and cyanide consumption, the costs are relatively high, and vary between 8 and 12 s. per ton of ore, according to local conditions.[12]

Apart from the fineness and efficiency of crushing, and the reduction of solution-value discharged with the residues, the chief directions in which future improvement may find scope are probably in reduction of time of slime-pulp agitation and aeration, the more perfect dissolving of the gold and silver with lower cyanide consumption, and their concentration in a much less bulk of solution, with corresponding reduction of the precipitation plant. These changes, if ever found practicable, would reduce power, cyanide, and precipitation costs, as well as lessen the size of plants, which at present greatly exceed in proportion those in operation on the Rand.

Life of the Kalgoorlie Mines.—With regard to the statement of Hermann Landau at the annual meeting of the Associated Northern Blocks, Ltd., that the producing mines of Kalgoorlie, so far as they could see, were approaching the end, the Premier of Western Australia has cabled to the Agent-General as follows:

"21st February, 1908.

"Government geologist reports main lode of Kalgoorlie belt may be divided into two groups, distinguishable as the Western or Boulder group and the Eastern or Associated—Lake View group. In Western group lodes are well defined quartz bodies, and they have been proved to a depth of from 1600 to 2200 ft., at which depth they carry higher value than at any point below the 1000-ft. level, and present every indication of permanence. The Eastern group consists of a belt of enrichment; contemplate a series of pipe or lenses of rich ore. These have been tested to a depth of 1700 ft., at which point there is every indication that this class of country will extend to as great a depth as the ore can be profitably mined. So far as observations have, however, at present been carried, there does not appear to be any scientific reason for believing that the mines of Kalgoorlie have by any means reached the limit of ore deposition, or that the lode will not as a whole prove productive in depth."

The statement made by Mr. Landau was criticized in the letter of our London correspondent appearing in our issue of February 15.

The Prospector.

NOTICE.—Owing to the large number of specimens forwarded to this department, it has been found necessary to make a charge of 25 cents (to subscribers) for each determination, in future.

W. C. M., of Imuris, Mex., sends good white clay.

The specimens sent by W. C. F., of Atlantic, Iowa, have not been received.

P. G., of Guadalajara, Mex., sends: No. 1, altered volcanic; No. 2, syenite.

S. S. S., of Winthrop, Cal., sends crystalline limestone impregnated with pyrite.

Specimens of black tourmaline rock were received from F. M. B., of Yerington, Nevada.

A specimen of gneiss, apparently a metamorphosed dioritic rock, was received from C. H. W., of Grizzly Flats.

Black sand was received from Alleghany, Cal., consisting of magnetite and chromite. No platinum is visible.

The rocks from El Paso, Tex., sent by L. & C., are: No. 1, metamorphic rock; No. 2 and 3, chert or flint; No. 4, altered feldspathic rock; No. 5, quartzite; No. 6, hornblende-porphyrite; No. 7, a metamorphic rock.

E. M. D., of Paris, Cal., sends: No. 1, breccia, mineralized; No. 2 to 4, quartz with pyrite and pyrargyrite; No. 5, stibnite and cervantite; No. 6, earthy limonite; No. 7, altered rock with graphite; No. 8, altered rhyolite.

The rocks from Silver City, N. M., marked T. L. G., are: No. 1, rhyolite-tuff; No. 2, chert; No. 3, chalcedony; No. 4, red sandstone; No. 5, rhyolite; No 6, sandstone; No. 7, rhyolite; No. 8, chert; No. 9, sandstone colored by protoxide of iron; No. 10, meta-rhyolite.

Specimens from Outlook, Wash., marked W. M., are: No. 1, tripolite; No. 2, clay; No. 3, shale; No. 4, granite; No. 5, aplite; No. 6, shale; No. 7, pegmatite; No. 8, quartzite; No. 9, limestone with calcite vein; No. 10, shale; No. 11, sandstone; No. 12, tripolite; No. 13, tripolite; No. 14, schist; No. 15, tripolite; No. 16, chalcedony pebble.

The rocks from Villa Grove, Colo., marked F. S. C., are: No. 1, feldspar and quartz sprinkled with pyrite; No. 2, hornstone; No. 3, granite-porphyry; No. 4, feldspar-porphyry; No. 5, hornstone; No. 6, quartzite; No. 7, altered feldspar-porphyry; No. 8, orthoclase-porphyry; No. 9, quartz; No. 10, quartz with pyrite and graphite; No. 11, quartz with chalcopyrite and sphalerite; No. 12, quartz with chalcopyrite, galena, sphalerite, and tetrahedrite; No. 13, rhodochrosite; No. 14, diorite.

Silica sand is not known to occur in California, and if a sand containing 98% of silica free from iron oxides could be found, it would be a valuable discovery. This material is used for the lining of furnaces, and is shipped in some cases from Minnesota to the Pacific Coast.

PRIMARY CHALCOCITE IN CALIFORNIA.

Written for the MINING AND SCIENTIFIC PRESS
By OSCAR H. HERSHEY.

In Del Norte and Humboldt counties, California, there are copper-bearing deposits that probably contain chalcocite as a 'primary' mineral. None of them is of economic importance, but they are interesting as representatives of an unusual type of mineral deposit. They occur as many small bodies of ore (frequently rich) unsystematically distributed through large masses of serpentine. This serpentine originally consisted of peridotite and related ultrabasic rocks that were intruded into the sedimentary formations during the Cretaceous period, and had by a sort of deep-seated weathering been altered more or less completely to serpentine. In the Klamath Mountain region, the serpentine areas are in places long and narrow, like dikes, in others they spread out so as to be five to twelve miles wide. There is usually much meta-gabbro and some altered pyroxenite associated with the serpentine. Copper ores also occur in the meta-gabbro, but the peculiar type under discussion is confined to the serpentine.

The best example noted is on the Cleopatra group of claims, situated in the northern part of Del Norte county, 24 miles by an old disused wagon-road or 18 miles by cut-off trail easterly from Smith River. It is in the midst of the largest serpentine area in the Klamath region. The ore consists mainly of chalcocite associated with a black iron mineral which, so far as I could determine in the field, is magnetite. These minerals form a fine-grained aggregate embedded in serpentine. There is no quartz, little or no pyrite, and no other minerals such as are common in ordinary veins. Near the surface there has been a little alteration of the chalcocite to malachite, producing a weak stain of green color, but in general these deposits resist weathering and outcrop almost in their original condition. The portion of the serpentine in which they are embedded is usually sheared and breaks down readily under atmospheric action; but the orebodies, being hard and tough, resist shearing and hence occur as 'cores,' which weather out and form masses of float varying from a few ounces to several tons in weight. They are rather widely distributed on the Cleopatra claims, but seem best developed in a north-south belt of sheared serpentine, which is about 300 ft. wide. There is no apparent system in the distribution of them through this belt, although many cuts and short tunnels have developed a series of them at close intervals along a line several hundred feet long. However, there is nothing about their occurrence here to suggest a vein. The individual orebodies are frequently lenticular in shape, but I attribute this largely to shearing around them subsequent to their formation. All the work done here has only yielded about 20 tons of ore that, by careful sorting, has been brought up to a possible copper content of 15 or 20%. The little orebodies are not sufficiently plentiful to make it practicable to work any part of the sheared serpentine as a large low-grade concentrating proposition.

Another interesting occurrence of this kind is in Humboldt county, on the divide between Red Cap and Boise creeks. A belt of serpentine averaging several hundred yards in width and many miles long follows one of the great faults of the Klamath region. Nearly everywhere it is thoroughly sheared, and being very slippery it has given rise to large landslides. This is the case where it crosses the ridge separating Boise and Red Cap creeks. When discovered, many years ago, the dike for a distance not exceeding half a mile was found to have distributed over it many hard masses of ore varying from a few pounds to probably five tons in weight. They were broken up, the richer portions sorted out, transported many miles on mule-back, and shipped to Swansea, Wales. The operation was not profitable, but the high percentage of copper gave rise to the Red Cap copper 'excitement.' It was assumed that these masses of float were derived from a continuous vein buried under the landslides that cover the solid serpentine dike, and a number of long adits were driven into the mountain, with negative results. Even in recent years, sporadic attempts have been made to find the source of the 'boulders.' Parties now prospecting there presume that there is a more or less continuous vein of ore on the uphill side of the serpentine. My impression is that nothing of value will ever be found there; that the 'float' boulders have been derived through the weathering of small hard bodies of ore distributed unsystematically and at wide intervals through the sheared serpentine. There are no seams leading to them, nothing whatever to guide explorations underground, and searching for a sufficient number of them to make a mine would be economically futile.

The Red Cap ore has no quartz and no pyrite; the gangue is serpentine and the most abundant mineral is mainly magnetite. The chalcocite varies from almost nothing to nearly 95%. Even from the float yet remaining, sacks of ore carrying 60 to 70% copper can be collected. An interesting feature is the presence in some of the best ore of cuprite and native copper. A little of these minerals also is present on the Cleopatra ground, where I have seen beautiful specimens consisting apparently of an intimate intergrowth of native copper, cuprite, and chalcocite. There was nothing about them, so far as I could determine in the field, to suggest that the native copper and cuprite had resulted from weathering of an original sulphide.

These copper deposits are apparently related to the Catini (Italy) type described by W. H. Weed in his book entitled 'The Copper Mines of the World.' At Monte Catini the orebodies occur in a mass of olivine gabbro or of diabase, and they consist of pyrite, chalcopyrite, bornite, and chalcocite, with rare sphalerite and galena; these minerals are either disseminated through the rock or gathered into irregular and roughly spherical masses or many-armed and branching stocks. The pay-ore is confined to serpentine, which has been crushed by expansion. The type includes the Libiola and other Ligurian deposits in Italy, and occurs at Wis and Rebelj in Servia and at Minas in Cuba; it is common in Turkey. Mr. Weed thinks the ore in this type of deposit was produced by segregation at the time

of alteration of the rock to serpentine. The deposits in California differ from those of Monte Catini chiefly in the presence in them of much magnetite and the absence of pyrite and chalcopyrite.

All authorities, in making up a classification of mineral deposits, place the Catini type under the general heading of 'magmatic segregation'; but there is a difference of opinion as to whether they originated by segregation from the molten magma or were formed during the serpentinization of the rock.

Magnetite is a common constituent of the serpentines of northwestern California; in places it makes 10 to 30% of them. In the associated meta-gabbros there are undoubtedly many grains of ilmenite and magnetite that crystallized from the molten magma, and in places they are concentrated into irregular bodies of low-grade iron ore. The magnetite in the serpentine may have had a similar origin, but I rather incline to the opinion that in its present form it is the result of serpentinization. Small irregular bodies of chromite produced by segregation are common in the serpentine areas of northwestern California. Some authors would consider them the product of magmatic differentiation of the molten mass, but the chromite frequently bears such a relation to the structure of the serpentine mass as to indicate that it is the result of the process of serpentinization. The chromite orebodies have the same form as the copper deposits under discussion; there is the same structural relation between the serpentine gangue and the mineral grains. Indeed, it is my impression that at a prospect half a mile south of Adams station on the Crescent City-Grants Pass stage-road in Del Norte county, chromite takes the place of the usual magnetite as the associate of the chalcocite. There can be little doubt that the magnetite-chalcocite deposits have had the same genesis as the chromite deposits. They have resisted oxidation and there has been no leaching of copper from near the surface and deposition deeper—no secondary sulphide enrichment. The minerals were originally deposited as oxides, a metal, and a high-grade sulphide—chalcocite. There was not sufficient sulphur present to combine with the iron, but generally sufficient to make the copper into chalcocite.

The localization of these deposits is interesting. Magnetite and chromite, as already stated, are common throughout the serpentine areas; further, copper ores of other kinds are rather widely distributed in these areas; but the association of copper with the magnetite and chromite is comparatively rare. Perhaps the molten rock came in contact with and absorbed rocks containing ordinary copper deposits, thus deriving an unusual copper constituent, which was widely disseminated in certain portions of the peridotite and related basic rocks, but during serpentinization became segregated with the iron minerals. However, it remains an open question as to whether the segregation was connected with the solidification of the magma or with the subsequent serpentinization. This discussion has been based entirely on field observation; the ore is worthy of mieroscopic study.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

A mineral lode in a mining district had for several years been located and abandoned by different persons. These various locators had driven an adit upon the vein, which, after the abandonment, had caved and filled with earth and rock, and was overgrown with weeds. In January, 1903, a locator placed upon this vein, near such adit, his discovery notice, but performed no work of any kind upon the claim. In March he erased the former date and placed a new date on the notice, but did not work. In May he erased the March date and placed another date on the notice. His work consisted in picking on from the foot-wall back toward the hanging wall, but he did not clear to the bottom of the tunnel; he then went up the mountain and picked down, but did not go to the top; but made a new face in the white porphyry about 12 ft. high. In a contest with a subsequent locator, this was held not to be a sufficient compliance with the statute providing that within 60 days from the time of making the discovery a shaft 10 ft. deep shall be sunk, or an open-cut, cross-cut, or tunnel, which shall cut the lode at a depth of 10 ft. below the surface shall be made, or an adit at least 10 ft. in along the lode from the point where the lode may be in any manner discovered, shall be made.

Ingemarson *v.* Coffey, (Colo.) 92 Pac. 908, Dec., '07.

The United States statutes give the miners of every mining district authority to make regulations not in conflict with any laws of the United States, or of any State or Territory, in which the district is situated. Under the regulations of mining districts in California which provide for posting two notices to establish a location, it is held that the failure to comply with such mining rules in this respect, would not work a forfeiture of title, in so much as there was nothing in the rule which made non-compliance a cause of forfeiture; that, unless the rule so provided, the failure to comply with its requirements would not work a forfeiture. This is the rule in California and Arizona. But the opposite is held in Montana and Nevada.

Yosemite Mining Co. *v.* Emerson, 28 Sup. Ct. Rep. (U. S.) 196, Jan., '08.

A miner whose duty it was to fasten a rope to certain timbers in the mine, to be hoisted to an upper level through a certain chute, was injured by reason of the faulty construction of the chute, by which one of the timbers caught upon the projecting sides of the chute and broke the rope, causing such timber to fall back and injure the miner. It was claimed that the miner could not recover because of contributory negligence in not standing clear when the timbers were hoisted. The rule applied was that contributory negligence, in its legal significance, is such an act or omission on the part of the plaintiff amounting to a want of ordinary care as, concurring or co-operating with the negligent act of the defendant is the approximate cause or occasion of the injury complained of.

Leary *v.* Anaconda Co., (Mont.) 92 Pac. 477, Nov., '07.

It was held proper, in an action by a miner for injuries by reason of timber falling back into the mine while being hoisted because of a defective chute, to prove that when the signal was given to hoist the timber through a raise, it was the general custom among miners for the man giving the signal to stand clear.

Leary *v.* Anaconda Co., (Mont.) 92 Pac. 477, Nov., '07.

In an action involving the construction of a deed conveying all the minerals and metals in certain land, it was held proper to admit the testimony of an expert as to the meaning of the word 'minerals,' and that it was proper for such expert to testify that shale was a mineral within such conveyance.

McCombs *v.* Stephens, (Ala.) 44 South. 867, Nov., '07.

MINE FIRES.

By Walter O. Snelling.

*In combating mine fires the use of carbon dioxide as a means of producing an atmosphere in which combustion cannot be sustained, has been many times suggested, and frequently tried, generally with a fair degree of success. The cost of producing carbon dioxide has been, however, a decided drawback, and the danger of producing carbon monoxide by the reduction of the carbon dioxide by heated carbon, and consequently bringing about an explosion, has also tended to prevent this method from being used.

The use of sulphur dioxide in combating mine fires has not, I believe, been previously suggested or tried, and yet the method presents such decided advantages over the use of carbon dioxide, that I now suggest the advisability of considering it as a cheap, convenient, and safe means for fighting stubborn mine fires, and I herewith present some statements to show the advantages which this method would possess.

(A) **Cost, Preparation, Etc.**—Sulphur dioxide is produced by the simple burning of brimstone on a grate of suitable kind, and of such nature as could be quickly constructed, even by inexperienced men. One ton of brimstone, costing $40, will produce 25,000 cu. ft. of gas, and allowing for all sources of loss, it is probable that sulphur dioxide can be produced for $2000 per 1,000,000 cu. ft. For carbon dioxide, produced by the action of sulphuric acid on limestone, the best estimate I have been able to figure is about $4000 per 1,000,000 cu. ft., or twice as costly as the sulphur dioxide.

(B) **Efficiency.**—Sulphur dioxide is more efficient than carbon dioxide in the putting out of fire. Neither coal nor any other combustible material can possibly burn in an atmosphere containing any considerable quantity of sulphur dioxide. Sulphur dioxide is very heavy, being almost twice as heavy as carbon dioxide (1 cu. ft. weighing 81 gm., while 1 cu. ft. of carbon dioxide weighs 46 gm.), and consequently the sulphur dioxide will penetrate into gob piles, and in every way serve as an efficient agent in finding its way into every part of the region of the mine into which it is introduced.

(C) **Safety.**—None of the dangers incident to the use of carbon dioxide are present with sulphur dioxide. No explosive lower oxides are produced, or can be produced by the reduction of sulphur dioxide. Still more important, the danger always present when using carbon dioxide, of men getting into the gas without knowing of its presence, and suffocating, is absent when sulphur dioxide is used, since its strong odor gives instant warning when but a small fraction of one per cent of the gas is present in the air.

(D) **Other Advantages.**—Any leakage of carbon dioxide from a mine can only with great difficulty be detected. Frequently, in places where this method has been applied, it is probable that millions of cubic feet of the gas has escaped through unknown fissures in the rock. Any leakage of sulphur dioxide would quickly make itself known, and the openings could accordingly be closed before more than a small portion of the gas had escaped.

Conclusion.—The extremely simple manner in which sulphur dioxide can be produced, the cheapness of the method, and the efficiency of the gas in putting out fires, would seem to make this a desirable means of combating mine fires. The safety of the method, its convenience, and its utility in showing fissures, which allow escape of gas and ingress of air, are also strong points in its favor.

*Abstract of paper read before the American Institute of Mining Engineers on February 19.

Passivity of Gold.— * * * In potassium cyanide solution, gold dissolves at the anode as a univalent ion. Passivity develops in commercial potassium cyanide solution at a small concentration, a brown color, due to paracyanogen, being noticed in the solution, but in pure potassium cyanide a much higher concentration is necessary. The presence of the sodium salt in the commercial substance is responsible for this difference and the cause of passivity appears to be the formation of an invisible protective coating of sodium aurocyanide on the anode, this salt being much less soluble than that of potassium (a fact which explains the superior efficiency of potassium cyanide over sodium cyanide for the purpose of gold extraction). A similar result is noticed in the case of nickel, which dissolves quantitatively in a solution of potassium cyanide but is rendered passive, it is now found, in the presence of sodium cyanide. The authors would extend this explanation of passivity to all known instances of the phenomenon. When, in the neighborhood of the anode, the solubility product of the ions of the protecting substance is reached (hastened in this case by the presence of more sodium ions), the protective coating is formed, rendering the anode passive.—A. Coehn and C. L. Jacobson, Zeits. Anorg. Chemie, 1907, vol. 55, p. 321-355.

Molybdenite is widely distributed, but seldom occurs in quantities that can be economically prepared for the market. It is successfully separated from the gangue by an electro-static separator to form a concentrate containing about 85% molybdenite, which has a value of about $350 per ton. This metal has remarkable effects on steel, when added as ferromolybdenum, but even better results are obtained by the use of a molybdenum-nickel alloy. Both of these are preferred to metallic molybdenum, which rapidly oxidizes if added to steel in the solid state. For forgings, shells, wire drawing, and machine steel it is especially valuable. To prepare the metal, the sulphide is powdered and placed in an open inclined crucible and heated to dull redness over a charcoal fire, the mass being frequently stirred to oxidize the sulphur. The remaining yellow powder is crude molybdic trioxide, and this is then put in a porcelain dish and leached with aqueous ammonia and crystallized ammonium molybdate prepared by evaporation. The ammonium molybdate is then ignited to form the dioxide, which is reduced with carbon in the electric furnace.

COAL ON PACIFIC COAST.

The production of coal to any large extent on the Pacific Coast is limited to the State of Washington. The output from Oregon and California has been altogether lignite or sub-bituminous coal, and the largely increased production of petroleum for fuel purposes in California has materially affected the coal-mining industry in these two States. The market in San Francisco at the close of the year presented some peculiar features. Both dealers and consumers of coal, having in mind the experience of the two previous winters, had purchased and stored during the summer all the coal which they thought would be demanded during the winter. As a result, as much business was done by the dealers in San Francisco during the summer months as is usually done in the winter. During the last three months of the year, in addition to the financial depression, there was a continued season of warm weather, with the result that no drain had been made upon the stocks stored during the summer, while constant shipments of coal from Australia and Japan were arriving to add to the already full stocks on hand.

The mining of coal in California during 1907 was limited to development work on the Stone Canyon properties in Monterey county. These properties passed into the hands of New York people during the year, and in the fall and winter construction work on a railroad about 25 miles long, from the mines to the Southern Pacific railroad at Bradley, had begun. The Mount Diablo and Corral Hollow mines were practically idle throughout the year.

In Washington during the first ten months of 1907 the coal-mining industry was in a highly satisfactory condition. During November and December, however, owing to the financial stress, the output of the mines was curtailed about 33%. The price of steam coal for the first ten months of the year averaged $4 per long ton, free on board at the mines. In the months of November and December it dropped to $3.25 per ton. Lump coal for domestic use, which was sold for the first ten months of the year at an average of $6.50 per long ton, dropped to $5.50 in November and December. These reductions in price, however, were not due entirely to the financial stress. During the summer a campaign of education had been kept up with the idea of inducing the consumers to lay in their supplies of coal during the summer and avoid the shortage of coal which had been experienced in the previous winter. Domestic consumers followed this advice and stored a liberal supply at comparatively high prices during the summer. The anticipations of a winter similar to the preceding one were not realized.

There was some complaint during the early part of the year in regard to car supply, but this was not of a serious nature. On the whole the car service was satisfactory. During the midwinter, when the Alaska trade was at its height (and this is the season when the largest coal supply is required for steamer purposes), the miners' organization succeeded in unionizing the mines owned by the Pacific Coast Co. Those of the Northwestern Improvement Co. were unionized about two years previous. The unionizing of the Pacific Coast Co. mines increased the rate of wages 20% and reduced the hours to eight at the unionized mines. The only serious labor difficulty which occurred in Washington during the year was at the mines of the Wilkeson Coal & Coke Co. at Wilkeson. These mines were closed on November 6 because of the refusal of the company to recognize the union and the stand taken by it for the same hours and the same wage scale as those in effect at the Carbon Hill Coal Co. mines at Carbondale. It is understood that the mines will resume operations on the open-shop plan.

During the first nine months of the year, owing to the unprecedented prosperity in other lines of industry, the majority of the English-speaking coal miners (who are really the only practical coal miners) entered into other pursuits, compelling the operators to use inexperienced Italian and Slav immigrants. The incompetency of this kind of mine labor has not only increased the cost of production but has also increased the liability of damage to life and property.

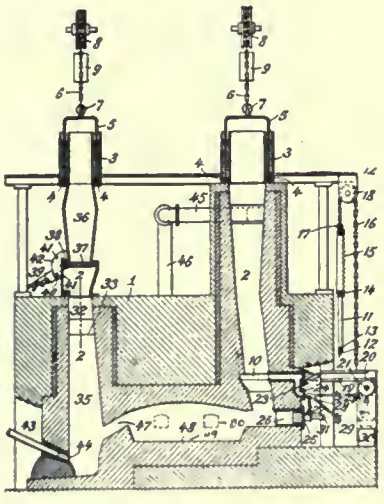
The unwatering of the 'deep lead' mines of Victoria has been useful in elucidating a number of problems connected with the raising of large quantities of water from great depths. Especially it has taught the most economical type of pumping machine. A number of types of steam-actuated pumping engines, as well as electrically operated Cornish plunger and centrifugal pumps, are in use. The result of experience indicates, without any question of doubt, that the most economical plant consists of comparatively high-speed compound or triple-expansion engines with rope drive, actuating gear-wheels, which in turn operate, through the usual connections, Cornish plunger pumps having a 10-ft. stroke, running at 10 strokes per min., the water to be elevated in stages not exceeding 300 ft. On the Loddon Valley there are four 26-in. plungers and one 22-in. The efficiency from throttle valve to water delivered is about 88%. The hydraulic gradient or angle of flow assumed by water in the pervious material filling these ancient river-beds, amounts to 8 to 10°. H. C. Hoover has pointed out that if we apply this knowledge to the subject of artesian wells it will tend to cast doubt on the theory now obtaining that artesian water often finds its source hundreds of miles away. Water may find its way to great depths from the surface because of capillary attraction and the laws governing the underground circulation of water. When it is tapped, it is impossible that the pressure causing it to rise several thousand feet to the surface can be due to hydrostatic head, because the hydraulic gradient would carry the lines of equal pressure to the surface long before they could reach the supposed outcrop.—C. S. Herzig.

Ferro-vanadium refines the grain and reduces the porosity of cast-iron as well as increasing the breaking strength. It is useful for such castings as valves and gas-engine cylinders.

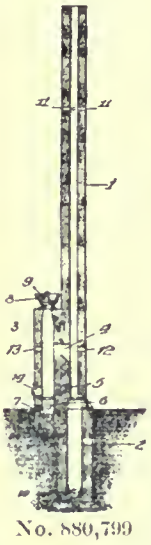
MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

PROCESS FOR THE REDUCTION OF COPPER ORE.—No. 879,530; Louis Durand, Dumont, New Jersey.



No. 879,530



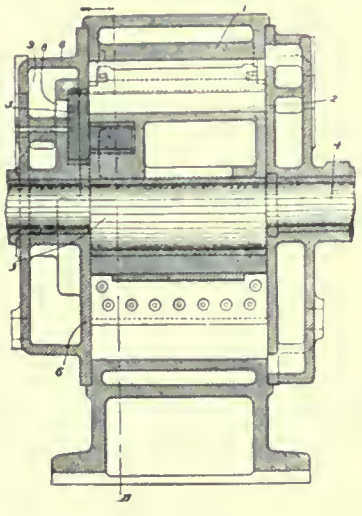
No. 880,799

The process for reducing copper ore which consists in subjecting copper sponge to the action of a reducent gas at a melting temperature, thereby melting the sponge and at the same time reducing the temperature of the gas, and utilize the gas at its reduced temperature to make more copper sponge.

METHOD OF REDUCING ORES.—No. 880,799; John T. Jones, Iron Mountain, Michigan.

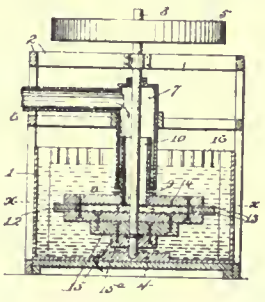
The method of reducing ore to recover the metal therefrom, which consists in mixing with the ore in finely divided condition coke, or the like, in lump form, thereby forming a column of the ore mixed throughout with such coke, or the like, to render the column interstitial, and passing through said column the hot products of combustion from carbonaceous fuel, to the exclusion of air and without smelting the ore, thereby reducing the metallic constituent of the ore to a metal state therein.

AIR-COMPRESSOR OR PUMP.—No. 879,213; William H. Tew, Glasgow, Scotland.

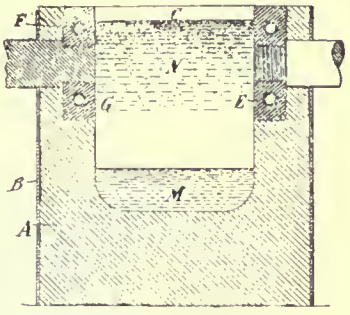


In an air-compressor, the combination of a stationary outer casing, an inner drum linked thereto, radial vanes operatively mounted in said outer casing and inner drum, a discharge valve or valves in said outer casing, means for imparting a rolling motion to the said inner drum, and inlet valves connected to said drum and adapted to be operated by the movement thereof.

FUME-ARRESTER.—No. 880,506; Selden I. Clawson, Salt Lake City, Utah.



No. 880,506



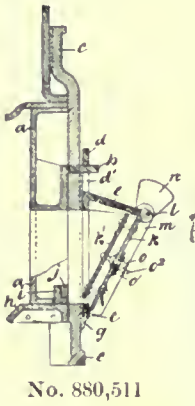
No. 880,743

In a fume-arrester, a fume-wheel having an axial fume-pipe leading into it, a ring carried by the wheel for discharging the fumes through the periphery of the wheel and forming an annular passage in the wheel from said pipe.

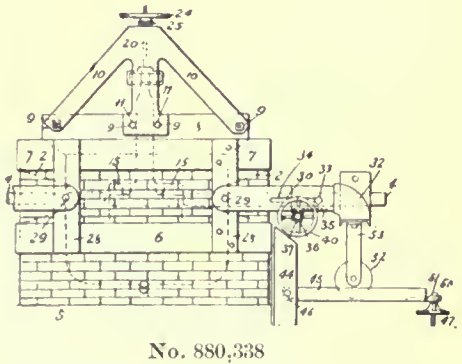
ELECTRIC-FURNACE PROCESS.—No. 880,743; Franz von Kukelgen and George O. Seward, Holcombs Rock, Virginia.

The method which consists in treating in an electric furnace a pyro-conducive charge by passing through it from a carbon electrode in contact with it a current sufficient to maintain the charge molten, and cooling said electrode to protect it from attack by the portion of the charge in contact with it.

FURNACE FRONT AND DOOR.—No. 880,511; Thomas Downie, Wallasey, and David Brown, Bootle, England.



No. 880,511



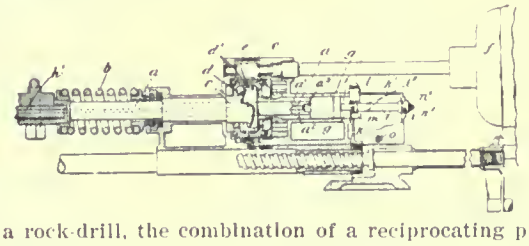
No. 880,338

In a furnace front internal protecting devices as *a*, a part thereon projecting through the front, and door frame, on the front adapted to engage with the part projecting through the front; substantially as described.

ELECTRIC-ARC FURNACE.—No. 880,338; Sidney D. Spence, Chattanooga, Tennessee.

An electric-arc furnace having a removable cover provided with openings, a fixed supporting element over said openings, a movable supporting bar, electrodes carried by said supporting bar and extending through said openings, screws connecting said supporting bar and the fixed supporting element, and connections between said screws to cause the same to turn in unison, for the purpose set forth.

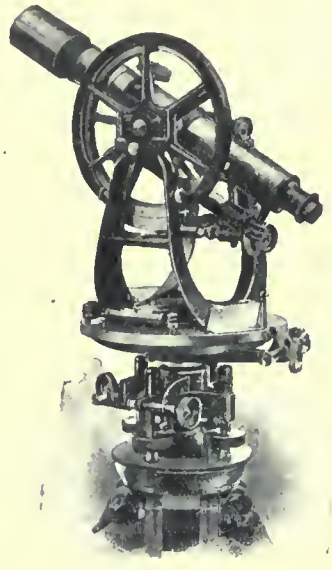
ROCK-DRILL.—No. 879,971; Bradford H. Locke, New York, New York.



In a rock-drill, the combination of a reciprocating piston, a reservoir in which air is compressed by the reciprocating piston, and means to discharge the air therefrom into the drill-hole.

A NEW THEODOLITE.

We illustrate herewith an improved theodolite recently placed on the market by Wm. Ainsworth & Sons, the well known instrument-makers, of Denver. The instrument is designated as their Type BU, and has a 10-in. 25-power telescope with 1¼-in. objective, 5-in. full vertical circle, guard, and vernier reading to one minute thirty seconds



telescope level, stadia and gradienter, 5-in. limb with verniers reading to one minute at 30° angle with telescope. The construction of the standard is such that it admits of placing a 2½-in. compass in the centre, which answers well for checking courses; most surveys now being made from a meridian established by solar observation; and for rigid-

ity and permanence of alignment the U standard is far in advance of the usual construction. All clamp and tangents are of the gib type, which when properly constructed are superior to the split clamps formerly used, in that they do not carry the instrument off the line when clamping.

The principal parts are made of the hardest bronze alloys to limit gauges, and interchangeable to the highest degree; the makers guaranteeing that any of the parts excepting

the limb, vernier plate, and centres can be interchanged with other of their instruments of the same size without throwing the instrument out of collimation to exceed fifteen seconds.

One of the advantages resulting from the use of gauges is shown by the leveling head, which cannot be cramped in any position, whereas usually when leveling an instrument it is necessary to loosen all four of the screws to prevent cramping. The cramping of the leveling head increases ten-fold the wear on the screws, and on lighter construction occasionally cramps the centres, this being the greatest objection to the four-screw or American type of leveling head.

Another of the excellent features of this instrument is the telescope construction, wherein accurate limit gauges also play an important part. The main telescope-tube is finished inside and out by lapping, as is also the outside of the draw tube, to within 0.0001 in. standard dimensions. The inside of the objective head, the outside and inside of the lens-cell, and the periphery of the objective are all of uniform diameter, true and accurate within these limits. The makers guarantee these as well as other parts of the same size instruments to interchange, with a resultant error in collimation of not to exceed the above amount.

COMMERCIAL PARAGRAPHS.

The Murray Iron Works, of Burlington, Iowa, have issued a catalogue, No. 60, describing their safety water tube boilers.

The Bristol Co., of Chicago, have published a booklet describing the varied and numerous application of recording instruments.

The American Steam Gauge & Valve Mfg. Co. has published a complete catalogue of valves, gauges, pyrometers, and other engine fittings. W. S. De Pierris & Co., 247 Pine St., San Francisco, are the local agents.

The Hendrie & Bolthoff Mfg. & Supply Co., Denver, Colo., announce that they have taken the western agency for Cameron pumps and will carry a full line of Cameron pumps in stock, and also spare parts. They also forward us their March announcement mentioning H. & B. Standard metal working crayons, Rock Island vises, triplex pumps, and so forth.

The Kilbourne & Jacobs Mfg. Co., Columbus, Ohio, is turning out a new line of dump-buckets which are being received with great favor, especially on account of their being conveniently handled. The dumping device is so arranged that they may be dumped from either side, and when righted is locked automatically. This device consists of a steel arm extending around the back of the bucket at the top edge, from bail to bail. When the bucket is righted, shoulders of the steel arm at each side are in contact with latch-bars which are firmly bolted to the bail, forming a secure latch and obviating any possibility of accidental discharge. The ends of the steel arm project so as to form operating levers. To dump the bucket the operating lever is raised at either side and both latches are completely released. This arm is so placed as to be protected from any possibility of being struck or bent, or distorted in any manner, being in continuous contact with the bucket and being placed immediately under the steel band with which the top of the bucket is re-enforced. This device solves the problem of constructing a bucket that will avoid the necessity of the operator being at only one side of the bucket, and solves it without the use of any intricate or fragile mechanism, the device being simplicity itself. The bucket is strongly constructed, being thoroughly riveted throughout, and is equipped with a false bottom of steel plate firmly riveted in place. The front, back, and bottom of the bucket are formed from one continuous sheet of steel, and the sides are stamped with a flange, through which they are riveted to the front, back, and bottom plate.

CATALOGUES RECEIVED.

The Western Electric Co. has issued a new catalogue of fan motors. The company carries a large stock of ventilating fans, which are fully described.

The Jeffrey Mfg. Co. have issued a booklet showing in numerous illustrations the diversity of uses in which their rubber belt conveying machinery can be profitably employed.

From the United States Geological Survey we have received the following advance chapters from the 'Mineral Resources of the United States' for 1906: 'The Production of Abrasive Materials,' by Douglas B. Sterrett; 'The Production of Sulphur and Pyrite,' prepared under the direction of David T. Day; 'The Production of Quicksilver,' by J. M. Boutwell; 'The Production of Lead,' by J. M. Boutwell.

PROTESTS are made occasionally against attacks upon wild-cats because, forsooth, it is asserted that many a prospect, which seemed a wild-cat, has developed into a splendid mine. The classification is mistaken. A young mine, no matter how young and unpromising, is not necessarily a wild-cat, if it is an honest enterprise. It is a kitten. Let us distinguish between the domestic, useful, and well-behaved pet and the fierce feline of the wilds. There are wild-cats and wild-cats; apparently, the king beast of his kind is the puma of the frozen North.

WITH THE BREAKING of the ice in Alaska, the season for active mining is just about to open. It promises to be highly successful. News of discoveries on the Koyukuk and Susitna rivers, as well as in the Tanana region, gives fresh incentive to exploration. It is said of many regions that they have not yet been scratched, this is more nearly true of Alaska than any other, for there the mantle of moss and ice cover the rock surface so as to require unusual persistence in prospecting. But the development of the territory is progressing rapidly, and Seward's purchase is proving one of the most fortunate transactions of history.

NOT MANY days ago Mr. Edgar Newhouse, chief advisory metallurgist to the Guggenheims, refused to meet Mr. Thomas W. Lawson at a meeting of directors of a copper company. Not long ago Lawson was regarded at 71 Broadway as a charlatan. Today he leads the circus parade. We do not wonder that Daniel Guggenheim escaped to Europe. When we contrast the reputation of the family twenty years ago in Colorado with their latest performance, we conclude that some people are more smart than wise. Evidently Mr. Lawson is to be their financial guide, instead of Mr. John Hays Hammond. We congratulate Mr. Hammond on having no responsibility for the latest departure of the smelter people. Even appendicitis is preferable to lawsonitis.

FINANCIAL CONDITIONS must have improved greatly to warrant the flotation of the two large mining companies recently advertised in the daily papers. As the promoters of these undertakings are shrewd men, well qualified to judge the condition of the money market, we accept the inference with pleasure. We discuss the Lawson-Guggenheim spoofery elsewhere, and further criticism will be submitted next week. The second important flotation is that of the Miami Copper Company, the stock of which is offered by the General Development Company of New York. The general character of the announce-

ment made by the promoters of this enterprise is as creditable as the Lawson affair is disgraceful. The capitalization of the Miami Copper Company appears reasonable when compared to the statement of ore reserves, production, and profit. One feature of the flotation is especially commendable, and that is the willingness of the vendor company to show all the contracts involved in the purchase and promotion, these documents being placed on file in a bank that is designated. The directors are men of the highest standing and one or two of them are more than that: they are men of unquestioned honor. The prospectus as advertised is couched in dignified terms and gives the essential information in a straightforward way. It is a striking contrast to the alarums and tom-toms of Lawson.

PROFESSIONAL MEN everywhere will congratulate Mr. Bulkley Wells on his merciful escape from assassination. He has been fearless in his fight for law and order in Colorado, and has risked his life repeatedly in the efforts to crush anarchy. The attempt to kill him with dynamite occurred in the very house in which Arthur L. Collins was murdered, by members of the same association. That crime has never been expiated by the punishment of the perpetrator, and Colorado stands disgraced until justice is done.

APPARENTLY the up-to-date promoter thinks the Hearst papers well suited to getting the kind of publicity required for mining schemes, for both Lawson and Lewisohn have used large spaces in the daily papers controlled by W. R. Hearst. This means that Hearst reaches the kind of people whose money is easiest separated from them, for transfer to the *haute juiverie* of New York. That financiers and business men who used to foam at the mouth when either Lawson or Hearst was mentioned, should now be willing to do their business through such mediums, is proof sufficient of their eagerness to make money, somehow, anyhow.

Concerning Rawhide.

ANATHEMA is not argument, but it has the merit of brevity. Some of our strictures on the queer doings that masquerade as mining have annoyed the people who have such a sacred regard for truth that they do not use it. Thus, by reason of reference to the silly exaggerations that have been freely employed in the stock-selling schemes of the Rawhide boosters, we have become charged with the intention to depreciate that new gold mining district wantonly and of malice aforethought. To our critics the exposure of wrong is regrettable because it hurts business. We do not share this point of view. To us all forms of dishonesty and clap-trap are hurtful to mining; we do not regard the Nat C. Goodwins, Larry Sullivans, and Industrial Development companies and the like of them as anything but leeches that sap the vitality of a grand old industry, and we hold that any mining district advertised by such people and such methods is hindered in its successful development. The rubbish printed by the local press has discouraged investors in the East: naturally sensible people ask why leasing companies with $400 ore sell stock instead of shipping ore. The iteration of sensational news will not make a mine. You cannot turn $12 ore into $400 ore by labeling it. Stuff that will not pan a color is not rendered profitable by a bogus assay certificate. A knife-blade stringer is an uncertain foundation for boisterous finance. Luckily there is rich ore at Rawhide and some of it is very rich, but even the real discoveries are doubted amid the atmosphere of mendacity deemed essential to a boom. Besides the one or two discoveries of rich ore, such as the Kearns leases, there are several wide lodes of fair ore that will require treatment on the ground in order to be profitable. This will come, but not with shouting. Intelligent development, followed in due course by the erection of mills, suited to the ore, will make Rawhide a productive district. No one will be more glad to record such industrial progress than this journal: no paper has greater contempt for the aero-thermal aspects of stock-jobbery than the MINING AND SCIENTIFIC PRESS.

The Clown and the Hippodrome.

THE hippodrome is Wall Street: the clown is Thomas W. Lawson; among the other performers are professional men of the highest standing; the on-lookers that throw their pennies into the four-ringed circus are the horde of simple greedy people, who accept the antics of the clown as finance, who rate the financial acrobats as philanthropists, who expect to get $10 for $5, and mistake the performance of a circus for the business of mining. Of all the impudent assaults on the credulity of the public, the prospectus of the Yukon Gold Company is the least excusable. Like an overture to a ballet, Lawson had previously issued several flaring notices hinting and promising something splendid in the way of a get-rich-quick scheme and we had read them as we read the advertisements of pink pills for pale people, for such stuff throws side-lights on human folly. We began to wonder what new imposition Lawson was going to foist on the public—the very public whom in a magazine article he recently flouted as "saffron-blooded apes" and "gelatine-spined shrimps," because they had proved unwilling to accept him as a reformer, having found out that he was an impudent scoundrel. But the wildest guess would never have imagined that the Guggenheims and all their cohorts of technical talent would be playing the harlequin to this clown of many stock exchange circuses. We would as soon have expected Phelps, Dodge & Co. or Lee, Higginson & Co. to enlist the services of Jack London or Carry Nation in disposing of the Copper Queen or the Calumet & Hecla. Not that the Yukon placers are comparable for a moment with the two enterprises mentioned. We say frankly that in San Francisco, where information concerning mining in Alaska is not wholly wanting, it has been supposed by those unfriendly to the Guggenheims that their Dawson investment was a rank failure, while those who are without prejudice have inferred, from reliable news, that at

best it was yet a doubtful venture. Whatever doubts existed are not removed by the statements quoted in the flamboyant prospectus of Lawson.

That prospectus probably garbles the reports and at best gives only fragments of the complete statements submitted by the engineers. Until we have seen the complete reports of Messrs. A. C. Beatty and O. B. Perry we shall withhold criticism, in the interest of the profession. It will be time enough next week to offer a critical analysis of the estimates. At the present writing we desire simply to express disgust at the prostitution of the mining business by such a fellow as Lawson. He shamed the cause of reform in America; he now makes mining ridiculous. Lawson offers a number of statements, unsupported even by the fragmentary quotations from the engineers' reports. In his latest advertisement he says that the "actual worth" of the stock is $15, that is, on a capital of 3,500,000 shares, the mines are worth $52,500,000, while the estimate given in his own prospectus is that $36,000,000 of profit will be forthcoming in 15 years, on which basis the present worth, allowing for interest (at the rate of 10%, the minimum for a gold mine) on capital, is less than $15,000,000. A small boy's arithmetic is all that is needed to demonstrate the absurdity of Lawson's wild assertions. Our readers do not need to be told that a placer mine is not like a vein mine; the latter has possibilities in depth, miracles may happen, and even the hungriest looking prospect may be the top of a great bonanza; such things have happened, although no sane man would base any estimate on such a doctrine of improbability. On the other hand, a deposit of gold-bearing gravel is limited in every dimension; it can be measured, and any unforeseen developments are usually of the wrong kind, that is, the total profits are much more likely to fall short of, than to exceed, sanguine anticipations. In this case, on the most reasonable of Lawson's many statements, the speculator pays one dollar on the expectation that if all goes well he will get a return of one dollar, and if any estimate is incorrect he will get less than one dollar, and meanwhile his dollar will be used by the philanthropist who invited him into the game. But, the reader will say, that is not the idea of such a flotation. The man who buys for one dollar expects to sell to someone else for two or three dollars; the intrinsic merits do not count; of course, there must be reports and so forth, but as long as well known men are directors and strong backing is forthcoming, the issue will be a success and there will be plenty of people to join in a stampede for the shares. So the speculator gambles on being able to unload upon someone more reckless and more greedy than himself; he plays the game for Lawson, he joins the Guggenheim people in the hippodrome, and finally some miserable simpletons hold the bag.

The mines are said to be rich, they are said to be fully equipped (which is not correct), they are said to be owned by people of high standing and enormous financial power. So says Lawson. Why then do they want to sell the stock? People owning good mines usually offer shares for sale because they have neither the money necessary for development nor the funds to build a mill or a smelter. It takes money to make even a good mine profitable. Hence the issue of stock in legitimate enterprises. But in this case the conditions are different. Lawson says that the Guggenheim group controls companies paying "enormous annual dividends," they have been "liberal and far-sighted in their expenditures for plant," and the mines are "thoroughly equipped." Why then the need of issuing stock to the public? Why, bless you, it is done out of sheer goodness of heart and thoughtful philanthropy. Anyone might have guessed that. Lawson makes it certain. He says that "leading bankers have sought to secure the whole or a portion of the Yukon stocks," but the Guggenheims would not part with their property. Was it because if they sold to the bankers they would get less than the money they had already expended, while on the contrary they could get their money and a handsome increment besides by disposing of stock to the public? No, Sir; they were anxious to give the widows and orphans a chance. Lawson says that "the group have been convinced that just at this time, when the people are filled with distrust of all things, it will be of inestimable value to the whole investment and corporation structure to spread through the land into the hands of thousands of small investors a fraction of the stock of their enterprise at less than one-half of its actual worth." Which means that to restore financial confidence throughout the country the Guggenheims are so patriotic as to give away a dollar for fifty cents. This is extremely probable. Next Lawson says that "the money lost to the group by selling" this stock "will be many times more than made up by the increase in value of the stocks of the other corporations in the group." *Credat Judaeus Apella.* In plain English, this is all preposterous flapdoodle. As for Lawson's part in the game, we surmise that he has an option on the 700,000 shares at about $4; the Guggenheims want money badly; Lawson wants money and notoriety; they will share the spoil. If this campaign of advertisement and buncombe succeeds, Lawson promises to startle the world shortly with a $60,000,000 scheme that will be a wonder. We venture to anticipate that it will be the Consolidated Copper Co. or Copper Mines Co., as last christened, a group that will include the Nevada Consolidated and the Utah Copper, which are two great copper mines, together with the Cumberland & Ely, which is a fairly good mine, and a number of smaller nearly worthless properties, and out of this watered stock Lawson and his harlequins will make golden wine, that is, if a miracle can be performed more than once. But what need is there to say more, has not Lawson described the whole performance in saying that "this story will be unique, inasmuch as it will be the first time in the history of stocks where a story relating to a security of great worth will read like the yarns usually spun in glaring advertisements by irresponsible wild-cat stock promoting swindlers." His glaring advertisement does indeed read like the yarn of an irresponsible wild-cat stock promoting swindler. It is.

Personal.

JAMES W. NEILL is at Butte.

F. H. MASON is at Paso Robles Hot Springs.

F. M. TAYLOR has returned to Denver from Goldfield.

H. W. TURNER is examining the Monterey coal mines.

FRANK KLEPETKO is on his way from New York to Peru.

W. S. MORSE and EUGENE B. BRADEN were at Goldfield last week.

F. D. BRADLEY is manager of a mine at Seven Troughs, Nevada.

C. HENRY THOMPSON has reurned from Mexico to Los Angeles.

E. M. HAMILTON is going from Salvador to England at the end of April.

W. H. WEED is examining the San Cayetano mine, at Guanajuato, Mexico.

F. L. MORRIS has gone to Dawson, on the Yukon, to be absent three months.

W. F. FERRIER, now residing at Montpelier, Idaho, was in San Francisco this week.

J. C. PRYOR is now metallurgist to the Montreal Reduction & Smelting Co., in Canada.

H. R. PLATE is president of the University Club at Ely, Nevada, which has 100 members.

THOS. R. BARBOUR is managing director for the Balaklala Copper Co. and is now at Redding, California.

J. H. BAKER is now stationed at Madera, California, where he is engaged in examining the copper belt.

HENRY C. CARR and JOS. G. HIBBS have formed a partnership, with offices in the Penn Mutual Bdg., Philadelphia.

E. D. MCDERMOTT, after a year's residence in Spain, has returned to Mexico. He is now on his way to Guanajuato.

EDMUND A. PRENTIS, Jr., recently in Peru, is now manager of the San Carlos-Providencia mine, at Taviche, in Oaxaca, Mexico.

HORACE V. WINCHELL fell down a winze and sprained his ankle at Goldfield, where he perforce remains for a couple of weeks.

I. F. LAUCKS and M. J. FALKENBURG have opened a general assaying and mining engineering office at 609 Opera Place, Seattle.

W. M. CAHOONE, formerly mine surveyor at the Bunker Hill & Sullivan mine, in Idaho, is now attending classes at Columbia University.

J. C. DUFRESNE has severed his connection with the Canadian Metal Co., on the completion of their new concentrator at Riondel, B. C.

R. B. HEGARDT, local manager of the Old Dominion Copper Co., has returned to Globe from a brief examination of the California copper belt.

JESSE J. MACDONALD has been appointed manager of the Engineering Department of the American Trading Co., with offices at 6-8 Critched Friars, London.

JAMES C. BENNETT has terminated his engagement with the Risdon Iron Works, San Francisco. He has been in charge of the department of concentrating and smelting machinery.

WILLIAM GOWLAND, professor of metallurgy in the Royal School of Mines, has been elected a Fellow of the Royal Society. Professor Gowland has been president of the Institution of Mining & Metallurgy during the past year.

HUGH ROSE has resigned as assistant general superintendent for the American Smelters Securities Co., to take charge in Mexico as general superintendent for the Guanajuato Development Co. and its allied interests, the Pinguico Mines Co., the Peregrina Mining & Milling Co., the Mexican Milling & Transportation Co., etc. Mr. Rose will have headquarters at Guanajuato, and an office at 40 Wall St., New York.

DIVIDEND.

On April 4 the Bunker Hill & Sullivan Mining & Concentrating Co. will pay dividend No. 127 of $75,000. This makes the amount of dividends paid since January 1, $225,000, and the total to date $10,071,000.

General Mining News.

ALASKA.

The strike situation at Douglas Island is serious. Eight hundred miners are now on strike, and troops have been sent from Fort Edward, Haines, Alaska, to preserve order. The troops have brought a gatling gun, as it is feared that serious disturbances may occur.

ARIZONA.

COCHISE COUNTY.

At a recent meeting of the Globe Con. Copper Co. held recently the financial position of the company was published. The cost of opening the Gem shaft was $246,257, while the expense of opening the Boston mine was $110,418. The company is capitalized for $1,500,000, and there is $500,000 of unissued stock in the treasury.——The Big O'Brien mill is operating steadily, making regular shipments of bullion and concentrates.

GILA COUNTY.

Deeds have been filed recently conveying to the Miami Copper Co. about 300 acres in the Globe district, situated about 6 miles west of the town. Part of this property was formerly known as the Oates-Newman group of claims. The first unit of the reduction works of 1000 tons capacity will be constructed at once.

YAVAPAI COUNTY.

A rich discovery is reported from the Turkey Creek district. J. Condor has found a 3-ft. vein, one foot of which is said to contain over 800 oz. silver per ton.——Recent developments on the properties of the Turnbull Development have shown some sulphide orebodies similar to those of the Old Dominion. One vein is said to be 10 ft. wide and to be of good ore, carrying 10% copper, with some gold and silver. This has been found in an old shaft, and an adit is now being driven to reach this and cross-cut the vein. The adit is now 400 ft. in length, and it should reach the vein within six weeks.

CALIFORNIA.

BUTTE COUNTY.

A contract has been let by the Butte Creek Con. Gold Dredging Co., which controls 1400 acres of land on Butte creek, for the construction of a $110,000 steel dredge. The contract was let to Edward L. Smith of New York. The dredge will be the largest in Butte county. It will be equipped with forty 11-cu. ft. steel buckets. It will be a floating dredge of the single-lift type. The sluice-boxes and gold-plates will be carried on an auxiliary boat. The boat is to be built especially to handle boulders, and the buckets will bring up boulders that will go through a hole four feet square.

CALAVERAS COUNTY.

Work will shortly be resumed at the Boston mine, under a working bond. The mine has been worked to a depth of 1000 ft., and is conveniently situated. It is equipped with a hoist and mill, water being obtained from the Mokelumne canal under a head of 800 feet.

EL DORADO COUNTY.

At the Alpine mine, the vein which was previously worked down to the 200-ft. level was recently encountered in the drift on the 300-ft. level. A cross-cut has been driven 18 ft. and is still in ore, which is mineralized throughout.——At the Searchlight mine, adjoining the Goldfield on the east, two shafts have been sunk to a depth of 16 ft., about 40 ft. apart, on a 2-ft. vein of quartz. Some good ore has been developed, and the prospect has been bonded. S. Beers of the Standard Unit mine will install a mill of his own design on the Wagner mine in Bear Creek district.——At the Little Chief mine a gasoline engine will be installed to operate the pump in the new shaft.

MARIPOSA COUNTY.

One of the richest discoveries in recent years was made last week in the White Gulch district in Mariposa county, about 4½ miles from Bagby, a station on the Yosemite Valley railroad. About two years ago H. Pearson, a prospector, located the Little Gem claim, in this district, but up to a few weeks ago he had never done much work. Returning to it about a month ago, he started work, and during the last four days he extracted $3000 and uncovered five well defined veins at a depth of 2 to 4 ft. which appear to be as good, if not better than his original pay-streak. The two principal veins on the Little Gem were uncovered at a depth of six feet, and were ½ in. and 1¼ in. in width, respectively, the former averaging two-thirds gold while the wider vein contained about 30% gold. Prospecting has shown many seams honey-combing the rock adjacent to this discovery. Most of the ground adjacent to the Little Gem has been staked, but owing to the extreme roughness of the country, the work of location has been difficult. The ground is strewn with quartz float for a radius of a mile and it is being actively prospected.

NEVADA COUNTY.

The gravel recently encountered in the Posey mine is proving extensive. From the raise a cross-cut has been driven 65 ft. without encountering the rim rock, and all the ground traversed carries a considerable quantity of gold.——It is reported that the Mountain Maid mine will soon be sold and developed systematically. The old workings are shallow.——A large body of quartz is being developed in the Chicago Park district by the Golden State Mining & Development Co. Two tunnels have been driven near the crest of Pine Grove hill. A cross-cut tunnel is now being driven 250 ft. below the old workings. The adit is now about 150 ft. long, and there is about 150 to 200 ft. to drive to cut the vein, which dips at about 30 to 35° toward the adit. Winzes were sunk to depths of 20 to 30 ft. in the upper levels, but sinking had to be abandoned owing to water. It was then decided to drive the lower adit.——Developments on the Mason ranch have opened a vein which is said to assay from $22.50 to $50 per ton. The vein has been developed for a length of 22 ft. and this new district is promising.

In the Bradshaw Mts., Arizona.

PLACER COUNTY.

At the executive committee meeting of the Anti-Debris Commission recently held in Sacramento, the dams around Dutch Flat were declared insufficient.——Three lessees are working on the Big Dipper channel.——An adit will soon be started from First Brushy canyon to open up the Slope, Wasson, and Blackhawk claims. A few men are at work cleaning out and re-timbering the adit at the Red Star on Devil's canyon. Work is progressing steadily at the Home Ticket, under R. L. Fletcher.——The El Dorado, which is nearly at right-angles to the Home Ticket, is turning out considerable profits, which repay the expense of finding it.

PLUMAS COUNTY.

Development work at the Arcadia mine continues to show ore, and the drift is 40 ft. long, on a shoot of good milling grade. It is probable that a deeper adit will soon be started,

opening the vein 300 ft. lower than the old workings.——Work has been resumed on the Lone Star mine by T. Treleaven.

Two shafts will be sunk to prospect for diamonds on the Cherokee property, owned by the United States Diamond Mining Co. Two diamonds were recently found in an eclogite similar to that at the Kimberley mines.

SAN BERNARDINO COUNTY.

(Special Correspondence).—Finds of valuable ore continue in the claims that are being worked, and last week the men working in the Sloan lease on Jumbo ran into high-grade ore at a depth of about 35 ft. An assay has not yet been made, but the pannings from the bottom of the shaft give about $250 per ton. Many of the claims are in ore, and prospects on claims to the west and north of the main range have resulted in good surface indications. Hart and Hitt's Foothill and Foothill No. 1 showed good pannings, averaging from $5 to $50 for a distance of 200 ft., while the Gray Horse claim, owned by Jennings and Goodwin, showed high-grade ore on the surface. The Ross and Blackburn lease has developed some more rich ore. There was a meeting of the Business Men's League of Hart held at Norton's hotel Saturday evening, at which all of the representative owners, lessees, and operators were present to discuss the conditions of the camp and the action of the several committees. H. S. McCallum, president of the league, who has been busy with the affairs of the camp in Los Angeles, made a lengthy report which created an impression. The Salt Lake railroad will aid in the establishment of an automobile stage line from Leestalk to Hart, making the rate equal to that of the Santa Fe, which runs closer to the camp. A siding will be built at Hitt, on the Santa Fe, four miles from Hart, and a freight-house erected at once. The commissioners of San Bernardino county have appropriated $1000 for a road from this station to the camp, which has already been surveyed, and upon which work will begin at once. Better time and connections are also promised.——On the Big Chief property the 500-ft. adit was started last week, and will pierce the mountain from west to east, cutting three known veins at depths varying from 350 to 500 ft. The shaft is down 25 ft. and continues to show high-grade ore. On Oro No. 1, Hart and Hitt are driving their 350-ft. adit which is expected to cut four veins, the last at about 150 ft. depth. Hall, superintendent of the Quartette Mining Co. of Searchlight which recently bought the Jumbo group, is in Hart with a shipment of timber and tools for the main shaft, which is being sunk with three shifts, in good ore all the way. Ore from this mine will probably be shipped to the Searchlight mills within a few days.——Twin Peaks continues to develop new finds, and in what was thought to be the foot-wall some high-grade ore was found last week. The double compartment shaft in this claim is down 40 ft. and cuts milling ore all the way.——The Todhunter lessees are still driving, and will raise for the shaft after going about 25 ft. more.——On the Stampher lease, Piute Belle, the shaft is down 50 ft. and they are now driving north and south, with the latter drift showing good ore. Maguire and Mahana are in 60 ft. with their adit on Oro Belle No. 1, and have a well defined vein assaying about $100 per ton. They will come farther down the hill, sink, and cross-cut for the vein.——Four claims owned by G. A. and W. L. Foster have been incorporated as the Hart Con. Mining Co., and work will begin April 1. The officers of the company are: George A. Foster, president; H. S. McCallum, vice-president, and W. L. Foster, secretary-treasurer and general superintendent.——The Pfunder lease on Oro No. 1 is cross-cutting from the 50-ft. level, to catch a well defined vein east of the shaft which traverses the Pfunder ground and the Big Chief. They will sink to the 100-ft. level as soon as they cut the vein.——Bevere, Barrow, and Furrow have started a shaft on the Rambler, which adjoins Jumbo and Clapper No. 3. Trenching showed good ore on the surface.——From 10 to 15 new people are coming in every day, and the demand for real estate and mining property is strong.

Hart, March 30.

The town of Hart is growing rapidly. A good two-story hotel is nearly finished, police and fire regulations are enforced, and a daily mail service is established. There are about 1000 people, and a large area has been systematically prospected. The best ground is on the Oro Belle claim, where a fair body of ore assaying about $90 per ton has been found.

SAN DIEGO COUNTY.

Increased activity is reported from Dulzura, the new mining district. Prospecting is being carried on over an extensive area, and some rich ore has been found at several points. About 1000 prospectors are in the vicinity, and several claims have been sold. The best property is three miles southeast of the little mountain town of Dulzura, which is situated among the foothills of the Otay mountains, close to the Mexican border line in San Diego county. Rich ore has been found over an area 7 or 8 miles in length and several prospectors have gone to Mexico to obtain concessions over the line. Hotels and stores are being erected, and a good sized town is springing up in the centre of the district.

SHASTA COUNTY.

It is reported that two more dredges will be built by C. A. Wertenberg to operate on the Sacramento river near Redding. These will be suction dredges, similar to the Dubois dredge which is operating at Middle Creek. Several dredges of this type have been built recently, and these are in operation in Shasta county and at Forest hill in Placer county.——The Bully Hill Copper Co. will soon start one of its blast furnaces. The Sacramento Valley & Eastern Railroad is completed, and coke and fluxes can now be hauled direct to the smelter.

The present capacity of the Mammoth smelter at Kennett is 1300 tons daily. The fifth blast furnace will soon be blown in and the output increased considerably. Custom ore is now being treated in the smelter, and it is probable that a large amount of custom matte will also be received from other smelters in California for conversion into blister copper.

COLORADO.

TELLER COUNTY.

The production for the first three months of 1908 from the Work Co.'s properties on Raven and Gold hills is more than $60,000. The greater portion of it has come from the Little Clara lease, operated by Humphreys and Thompson. Twelve lessees are at work on the various properties, and several of them are in ore.——Stafford & Co., lessees on the Midway property of the United Gold Mines Co., loaded a car of medium grade ore recently. The ore is broken on the 250-ft. level and averages $35 per ton. The shoot is thought to be an extension of the Wild Horse vein.

On the Black Diamond claim on Womack hill, under lease to Doepke & Co., extensive development work is in progress on a vein opened recently. Driving on the vein was started from the bottom of the 140-ft. shaft. At present assays indicate that the ore will average 3 oz. per ton for a width of 2½ ft. across the vein. The lessees are rapidly preparing to start a big production. A large body of low-grade oxidized ore, the extent of which has not been ascertained, will be explored. Assays taken from time to time seem to indicate that the whole dike will run about $7 per ton.

Jackson and Redd, lessees on the Amanda claim at Windy point on Bull hill, shipped a car of ore recently that carries 1 oz. per ton. The ore is broken from between the 50-ft. level and the surface. The lessees are looking for a vein which they have reason to believe will be cut in a short time.

There are but two sets of sub-lessees at present on the John A. Logan on Bull hill, and no work is being prosecuted by the Western Investment Co., who hold the lease. Jones and Motchison, lessees on Block 221, will make a shipment of 30 tons soon. The ore is mined in the adit on the property about 800 ft. from the portal. Gold is found in a basalt vein about 2 ft. wide and assays $18 to $20 per ton. Jones and Long, who are operating on Block 220½, loaded a car of ore recently that will assay about 1 oz. per ton. The

ore is broken from an open cut about 15 ft. wide. A streak in the shoot carries $70 per ton, which, with other small stringers, brings the average to ¾ oz. per ton.——Considerable prospecting is being prosecuted by the lessees, and shipping is regular, about 8 cars being loaded out. A steam hoist will soon be installed on the lease, and with the added facilities for production heavier shipments will be made.

NEVADA.

CHURCHILL COUNTY.

A discovery has been reported from an old settlement called Shady Run, about 40 miles east by north of Fallon. Rich specimens of gold ore have been brought to Fallon and many people have rushed to the scene of the discovery.

ESMERALDA COUNTY.

The old workings of the Sheets-Ish lease on the Combination ground caved last week, tipping over the gallows-frame

A Camp Store.

of the vertical shaft. The Consolidated officials have built a fence around the affected area. The ground caved is that which was opened through the incline shaft and which started the apex controversy between the Combination and Mohawk mines. The cave was attributed to the water from the mills.

The value of the week's output from Goldfield is estimated at $148,626, distributed as follows: Combination mill, 685 tons; Goldfield Reduction Works, 839; Western Ore Purchasing Co., 495 tons. The weekly shipment from Tonopah on the Tonopah & Goldfield railroad consisted of 4353 tons, valued at $95,000. This includes MacNamara, 104 tons; Tonopah Extension, 99; West End, 60; Tonopah Co., 2050; Belmont, 660; Montana Tonopah, 1100; Jim Butler, 100; Midway, 180 tons.

HUMBOLDT COUNTY.

Some rich gold ore has been found at Monte Carlo, in the vicinity of the Carpenter Black Diamond mine, within a short distance of the Western Pacific grade between Winnemucca and Hot Springs. The vein is said to be 10 ft. wide, and gold has been found by panning over a large area.

The Wihuja Gold Mines Co., operating the Stoker lease on the Therlen estate, broke into the west extension of the Kindergarten vein last week. High grade ore will be shipped from a 20 in. streak, and a large body of milling ore of good grade is being developed. The ore has been found at the 225-ft. level, about 50 ft. from the place in which rich ore was recently discovered on the Kindergarten. The Kindergarten workings connect with the inclined shaft of the Wihuja Co. on the 150-ft. level, which proves that the recent find is the same vein as that producing rich ore on the Kindergarten.——The lessees on the Eclipse property have recently cut the vein on the 70 ft. level, and found 6 ft. of milling ore with a streak of shipping ore varying from a few inches to a foot.——Work is progressing on the Kindergarten and Mazuma Hills stamp-mills, which are being erected in Seven Troughs canyon. The framework of the Kindergarten mill is completed, and the ore-bins and Wilfley tables are in place. The material for the Mazuma Hills mill has been brought from Lovelock, and also a 40-hp. Fairbanks-Morse gasoline engine. The mill will probably be completed in six weeks.

NYE COUNTY.

(Special Correspondence).—Four mills are now operating in Manhattan, two having a capacity of 10 stamps each, one Huntington mill, and another small plant. It is proposed to increase the capacity this summer.——The Manhattan Ore Reduction & Refining Co.'s plant on Mustang Hill is working on a large ore contract with the Consolidated mine; the ore at present being treated is from the full width of the vein, and runs about $25 per ton; but there are many tons of much higher grade which will be put through separately. This contract will keep the plant running for over six months; meantime the Consolidated is stoping ore, running drifts, and preparing to sink from the 200-ft. level. ——The Thanksgiving has reached a depth of 350 ft. and is cross-cutting east and west, the best ore being in the east drift, and several rich streaks have been encountered. The average grade of ore is over $50 per ton. At the annual meeting to be held in a few days the subject of erecting a company mill and proceeding to sink to the 450 level will be taken up. As soon as the Canyon Milling Co. completes the installation of a cyanide equipment they will treat a small lot of high grade ore from this property.——The Canyon Milling Co. is doing good work on small lots of ore, and has already made clean-ups from the Riggs-Lalime lease on Litigation hill, the Wolftone mine, the Plamanez lease on Union No. 9, and others. By taking these small lots, running from 100 to 500 tons, lessees are enabled to do steady work, paying for same with their returns.—— The Nevada Milling & Ore Purchasing Co. has been treating ore from the old Briggs-Evans-Sinclair dumps on Union No. 9 and from the Rose-Nash lease on Union No. 4.——Now that the town is equipped with mills, lessees are commencing to operate. On the Breyfogle estate, adjoining the Thanksgiving on the southwest, the Poak lease is continuing the main shaft from the 250-ft. level to pick up the rich ore-shoot of the Thanksgiving at depth. The Putney lease on the Gold Wedge estate is down 250 ft. and has done over 200 ft. of cross-cutting, having gone through several

At Dulzura, California.

veins of fair milling grade. This lease is being actively developed. Two lessees are operating on the Buckboard claim, adjoining the Litigation Hill tract. On the Seyler-Humphrey estate four lessees are operating. On the Litigation hill ground are the Rose-Nash, Riggs-Lalime, Wilson McNeil, Stewart, Watson, and other lessees, all doing good work. On the Earl claim two lessees are working, the Lorman lease having just run into some high-grade ore, similar to the rich streaks encountered on the Rose and Riggs leases at the 75-ft. level.——Thanksgiving hill is about a mile from Litigation hill, and to the south of that hill lies Gold hill, about half a mile distant, from which all the early shipments of high grade were made by the Union No. 9, Stray Dog, and other lessees.——The small plant of the Manhattan Milling & Leasing Co. is treating rich ore from

the Shea-Davis lease on Union No. 9.——The Mineral Hill property, situated over the East Manhattan range of hills, has good ore in the lower workings, and the management is arranging to install a power plant for deeper working. The present main shaft is down over 200 ft., with several hundred feet of underground workings.——The Otero, adjoining the Mineral Hill, is down over 250 ft., with considerable underground development. This property is equipped with power plant for deeper work.

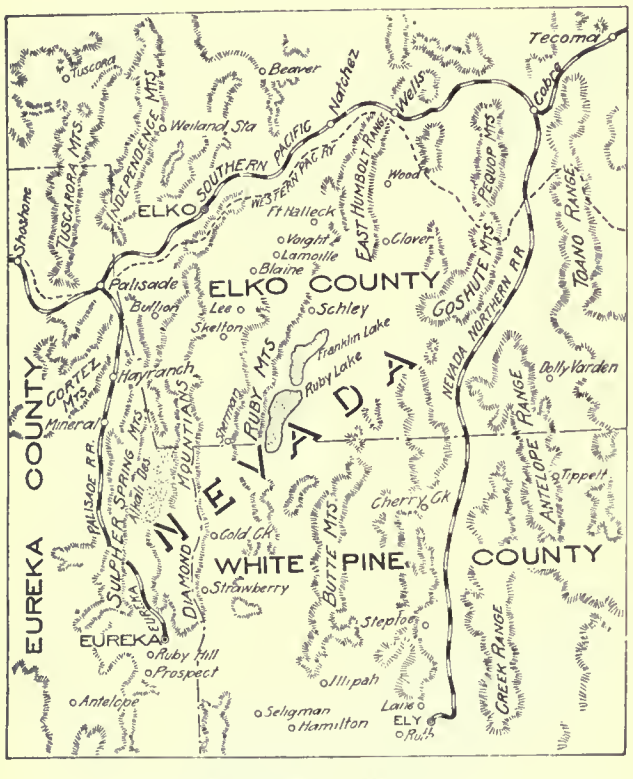
Manhattan, March 31.

LINCOLN COUNTY.

The Victor-Queen Bee Mining Co. is reported to have found some rich ore in Eldorado canyon. Tellurides have been found in a vein 8 ft. wide.

WHITE PINE COUNTY.

The Alpha shaft of the Giroux Con. Mines Co. has been repaired to the 1000-ft. level, and as soon as it is cleared to the 1100-ft. level, sinking will be resumed, and regular



Map of Eastern Nevada.

cross-cuts and drifts driven at each level. The water now developed in the shaft amounts to 70,000 gal. per 24 hr., and this will be used to run the concentrator for one shift. The rest of the water for the 600-ton mill will be supplied by a pipe-line from the Magnuson ranch, five miles east of Ely, where the company has a water-right. Reports state that 4,000,000 tons of concentrating ore and 350,000 tons suitable for direct smelting are in sight.——Excitement continues at Blaine, and many people have left Ely for the scene of the discovery of some rich ore. The Granite district has attracted large numbers. It is 30 miles north of Ely, about 5 miles from the Nevada Northern railroad. An important discovery is reported in the old workings of the Blaine tunnel. The vein is said to be wide and of good value.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The Snowstorm mine, which has been running with a crew of 60 men and putting out about 100 tons of ore per day for several weeks, has increased its output to 250 tons, and has added 40 men to its crew. This was brought about by contracting with the Trail smelter at Trail, B. C., for 150 additional tons, its previous contract being two or three carloads per month.——The Last Chance mine at Wardner has again suspended operations. The Standard and Mammoth is now the only mine of the Federal Smelting & Refining Co. in operation.

Spokane, March 30.

UTAH.

PARK COUNTY.

The recent find on the Wabash property at Park City is important. The work being done on the new vein is on the 1400-ft. level. A drift has been run for 250 ft. along the hanging wall of the vein. A cross-cut has been driven 86 ft. which proves the vein to have a true width of about 50 ft.——A new company has been incorporated to develop the old Sunshine mine in the Mercur district. The officers include several officials of the Con. Mercur Co. The property includes a mill which is in fair condition. The ore is similar to that of the Con. Mercur mine, on which such good work has been done by the mill recently erected by that company, so that the metallurgical treatment of the ore will present no serious difficulties.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—The Grant Con. Copper Mining Co. has made its final payment on the bonds covering the group of claims it has been operating near Chesaw, Wash., and has received a deed to the property. The last payment was $12,000, and completes $100,000 expended on the property by the Grant company since it took the bond a year ago. Development has been steadily carried on, and two veins have been cut in the adit, both containing high-grade chalcopyrite. The main lode was tapped by a short adit near the summit of the hill, and showed ore of shipping grade. This was followed up by a long adit lower down, which several weeks ago passed through a mineralized lode 46 ft. wide in which some concentrating copper ore was exposed. The adit has now reached the second vein, which was cut above, and it is found to be mineralized, but as yet no ore has been found. A railway spur has been assured when ore is exposed in paying quantities, and it is probable shipments will be made this summer.

Chesaw, March 27.

SPOKANE COUNTY.

(Special Correspondence).—The Pend d'Oreille Dredging Co. has been organized in Spokane to dredge for gold at the confluence of the Pend d'Oreille and Columbia rivers. The rich deposits of gold known to exist along both streams has led to the supposition that in the eddy at this point gold may have been deposited in the pot-holes at the bottom. It is well known that at many places along these rivers, especially the Pend d'Oreille, the same ground is worked year after year, the gold being brought down with succeeding freshets. No one, however, has ever succeeded in dredging the depths of the river at this point, although companies have been organized for this purpose. Frank F. Fullmer has now located one claim and will make the attempt to reach this gold. He has now gone to the East to examine dredges with the view to securing one able to bring up a heavy load from great depth.——It is reported here that a deputy sheriff has seized the mines and smelter of the Sullivan Group Mining Co. for debt, the amount being about $1600, representing the earnings of a number of workmen who have not been paid by the company. The Sullivan closed both mines and smelter the last day of February. Confirmation of this news could not be gained at the company's headquarters in this city, and the belief was expressed that the mines and smelter could not be seized in this manner, as they are already in the hands of trustees for the bondholders. The management issued a letter from its Spokane office March 17, stating that an assessment of 7 c. per share would have to be levied in order to pay off $225,000 owing to the Federal Smelting & Refining Co., and a floating indebtedness of $50,000. Answers to this proposal have not yet been received, but it is stated by the management that if this meets with approval by the stockholders, all financial difficulties will be cleared up, and operations again resumed.

Spokane, March 28.

STEVENS COUNTY.

The Cedar Canyon Smelting & Reduction Co. has a bond and lease on various mines near Deertrail which produce copper sulphides and lead and silver ores. It also has a lease on the Turk smelter, which consists of a Blanchard wood-burning blast-furnace, which did not prove a success. The ore has been hand-picked and the higher grades shipped to Tacoma. It is proposed to remodel the old smelter and resume operations with coke. Deertrail is 25 miles from Springdale and 35 miles from Davenport, on the Northern Pacific railroad. The freight rate is $6 to Tacoma and treatment charge is $8 per ton. The shipping ore assays over $50 per ton.

WHITMAN COUNTY.

(Special Correspondence).—The Mizpah Copper Mining Co. held its annual meeting at Palouse a short time ago and elected the following officers: President, C. E. Frederick; vice-president, J. C. Northrup; secretary, H. C. Johnson; treasurer, W. F. Chanler. The statement showed that $20,000 had been expended in development during the year past. It was decided to begin operations soon, and place the mine on a shipping basis as soon as possible.

Palouse, March 27.

CANADA.

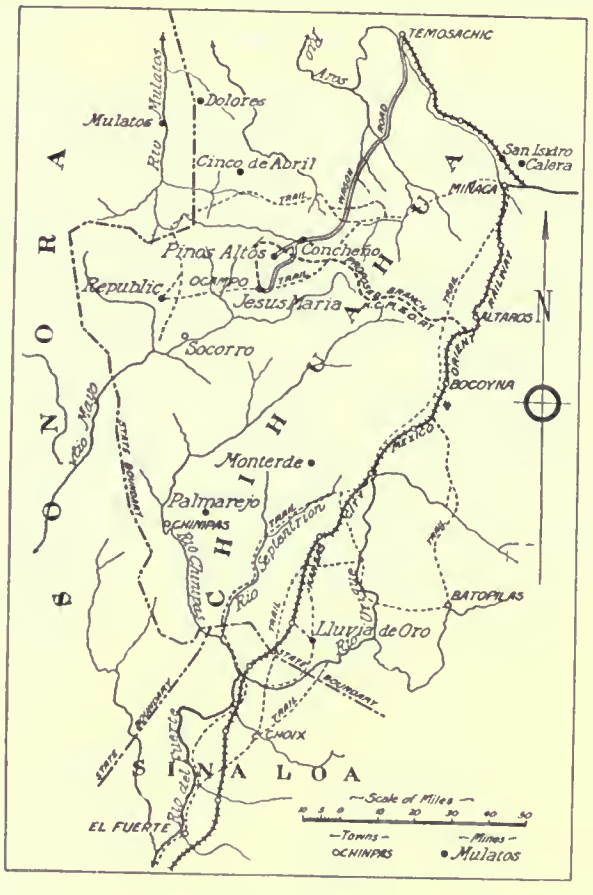
BRITISH COLUMBIA.

Improvements at the Granby smelter are being made which will cost $200,000. New ore and coke bunkers are being built, and the blast-furnaces are to have new water-jackets, and will be made 4 ft. 4 in. longer, making them a length of 22 ft., and increasing the capacity of the plant by 1000 tons per day. The converter plant will be entirely renewed. At present the converter plant can only just handle the product of the furnaces, though operating at full capacity 24 hr. per day. The present three converters are 70 in. diam. and 100 in. long, and the three new converter stands will be 84 in. diam. and 126 in. long, there also being 10 new shells. To make room for the enlarged converter plant, the steel converter building will be lengthened 80 ft. The new converters will be electrically operated, the first of this type in the Boundary district, and will be operated by 25-hp. electric motors. In the blower building the engine capacity will be doubled. At present the engines have 500 hp. capacity, and a new 500-hp. engine has been ordered, with a 500-hp. motor to drive it. It will be of double-cylinder type, capable of furnishing 10,000 cu. ft. of free air per minute with 15-lb. pressure, and will be, like the others, of Nordberg make, from Milwaukee. To supply the additional blast needed for the furnaces, necessitated by their being considerably lengthened, contracts have been let for two new Connersville blowers, each having a capacity of 30,000 cu. ft. of free air per minute. To operate these blowers there will be four 150-hp. electric motors, all new ones to be of Canadian Westinghouse type. With the enlargement of the blast-furnaces will also be required additional trolley engines to haul the feed cars from the coke and ore bins. Four of these trolley engines, each 30 hp., are now on the way to Grand Forks from the makers in the East. All of the above machinery has been contracted for with the explicit provision that it is for delivery on or before July 1. As soon as it arrives the work of installation will be at once started, one furnace being changed over and enlarged at a time. This will slightly cut down the smelting capacity for a short time, but when one or two furnaces are enlarged, the increase in size will make up for other furnaces being out of commission temporarily to undergo the same change.

The Blue Bird mine has developed a vein of rich ore four feet wide. The adit is driven a distance of 50 ft. and a machine-drill is being used. The work is being done by lessees.——The Nest Egg has been leased to Morrish, Grant, and Harvey. There is a shaft 75 ft. deep on the property, and an adit is being driven to tap the water in it.—The following shipments were made last week: Rossland district—Centre Star, 3270; Le Roi, 1865; Le Roi No. 2, 665; Evening Star, 35 tons; Boundary district, 25,388; Slocan-Kootenay, 1969 tons.

ONTARIO.

(Special Correspondence).—Discoveries of rich silver veins in the unsurveyed part of Lorraine township, near the Cobalt camp, have caused a rush to that district, where many new claims are being located. Several of the new veins have been located near the properties owned by the Cobalt Central Mines Co., upon which as yet no development work has been done. At the Josey claim, which is one of the new locations, 250 bags of high-grade silver ore are already sacked and are now being hauled to the shore of Lake Temiskaming. Twenty tons of silver ore from this new district will be shipped in the early spring. The discovery of silver outside the Coleman district, where the producing mines are mostly situated, is important. The new vein on Lot 38 of the Cobalt Central has turned out to be as rich as the No. 2 vein on Big Pete, and promising new veins have been encountered on the Right of Way, Silver Queen, Nipissing, Tretheway, and several other properties, The new No. 4 vein on the Silver Queen is now one of the richest veins in the camp. Two other good discoveries have been made on this property within 1000 ft. of the main shaft. Even the low-grade ore in the Cobalt camp is now



Map of Part of Mexico.

being shipped at a profit. The Nancy Helen has just shipped 40 tons of low-grade ore across the continent to the Consolidated Mining & Smelting Co.'s smelter at Trail, British Columbia.

Cobalt, March 25.

MEXICO.

Ore is being shipped by the Fe, Cavidad y Anexas Mining Co. from its Los Leones property in the Guachinango district to the Aguascalientes smelter.——The Mexican Agency Ltd. of London has taken an option to purchase a controlling interest in the Mina Grande, on the Santiago river in the Hostotipaquillo district. The Mina Grande is an 'antigua' that was worked from an enormous surface cut 500 ft. wide. Some of the pillars left in the mine are rich in silver and gold. By driving an adit from the adjacent river, a depth of several hundred feet below the old workings can be obtained.——Work has been begun on the erection of a cyanide plant and an electric power installation to be used in connection with the El Salto mill of the Green Gold-Silver Co.

Special Correspondence.

LONDON.

The Chartered Company.—Financial Arrangements.—The Spassky Copper Company.—A Spanish Copper Fiasco.

A few weeks ago I recorded in this column the propositions made by the directors of the British South Africa Company for the raising of further working capital. I mentioned that the scheme was to offer £1,000,000 of new shares for subscription at par, with the right to subscribe for further issues at the same price during the next three years. I pointed out that the present price for shares in the market was 15 shillings and that self-preservation and patriotic feelings were the only inducements that could be used in appealing for subscriptions to the new issue. Unfortunately this issue has not been a success, and the directors have been obliged to withdraw it. A variety of causes can be given for this failure. One is the general stringency of money. It is possible that in times when people had more cash the money might have been raised. Another contributing cause is the feeling that Rhodesia must be governed on a different basis, and that a position of aloofness on the part of the shareholders would do a good service in hastening the denouement. Thirdly, the hope of a dividend is so remote that shareholders do not care to put up any more funds. Be this how it may, the directors have now submitted an alternative offer. This takes the form of the issue of £1,000,000 in second debenture stock, bearing interest at the rate of 5½%, as part of £1,750,000, which it is proposed to create. These debentures will rank next to the first mortgage debentures, of which there are £1,250,000 bearing interest at the rate of 5%. The holders of the £1,000,000 of second debentures will have the right to convert their holdings into ordinary shares and to subscribe for two more ordinary shares at par during the next three or four years. It is by no means clear that this proposition will be any more acceptable, for there is no guarantee that the company will be able to pay the interest. A month ago, when I wrote my paragraph about the issue of new shares, I do not think that the public quite realized the seriousness of the position of this company, and my view of things may have appeared sentimentally exaggerated. Since then the state of affairs has been more accurately gauged, and it is quite probable that sufficient shareholders will now come forward ready to make some sacrifice for the sake of the Empire.

The directors of the Spassky copper company are bringing forward a proposition for the purpose of providing suitable equipment on a large scale. This mine, as your readers are aware, is in Siberia and contains one of the most solid deposits ever discovered. I gave full details of the mine as then developed in another place some two years ago, and my article appears in Weed's 'Copper Mines of the World,' so that it is not necessary to enter into any great detail now, except to say that further developments at depth show that the ore continues to be of the same high grade. Originally it was hoped to pay for equipment out of income from the high-grade ore, but more recently it has been suggested to the directors by several prominent men that full advantage of the high and low-grade ores can only be taken by spending money out of the capital for the purpose of erecting suitable plant and equipment. It will be remembered that Pellew Harvey & Fell have had the development of the property in hand, and that E. T. McCarthy confirmed all their estimates and views. More recently W. A. Heywood went from America to report on the ore treatment, and M. Robellaz of Paris examined the property on behalf of French capitalists. The last two gentlemen have strongly recommended the provision of this new capital. It is proposed to increase the share capital from £300,000 to £500,000, and the debenture issue from £129,300 to £300,000. At the present time it is only intended to offer the new debentures for subscription, which will provide funds amounting to £170,700. Of the new share capital, £100,000 will be held against the conversion of the debentures, and the remainder will be reserved for future issue whenever it is considered advisable further to develop the coal mines belonging to the company. The present issue will be used in completing the construction of the railway from the mine to the smelter, and building coke-ovens. It will also provide concentrating plant for treating the lower-grade deposits, which it is advisable to treat concurrently with the higher-grade ore, in order to supply the necessary sulphur for treating the latter. The coal mines at Karagandy promise to become an important asset of the company. They are sunk to 240 ft. and extensively developed, and are opening up practically inexhaustible quantities of good coal. The railway from the coal mine to the smelter, 26 miles, is already completed, and the smelting plant capable of producing 300 tons of copper per month is now ready to commence work. The present issue of debentures, which bear interest at 6%, should be an attractive investment.

A copper mine of recent flotation that has done badly is the San Vicente, which was floated with others as the Anglo-Spanish Copper Co. just a year ago. The mine is in

On the Zambesi.

the south of Spain, just on the border of Portugal, and is situated about half-way between the Bason & Barry and the Tharsis properties. It belonged for many years to Señor Yglesias and his friends, who first tried to sell it to the adjoining companies and subsequently attempted to work it themselves. A year ago it was sold in London to the Anglo-Spanish Copper Co., which was formed for this special purpose. The people who put up the money in London were eminent men connected with the metal trade, and the prospects seemed exceptionally good. A short time after the flotation the company appointed Charleton Dickinson & Co. as consulting engineers, and the directors were considerably disturbed when they received this firm's report. The report was not at all favorable; in fact, the firm was obliged to say that Mr. Rivington, on whose report the company was floated, was quite mistaken as to the extent and value of the ore deposits. The directors, after consultation with some of the principal shareholders, agreed to the proposal of the French shareholders that Messrs. F. & F. Gouin should go out to make a further examination. This was done, and their report confirmed that of Charleton Dickinson & Co. The shareholders who had put up the money on the flotation subsequently met together and determined to request the vendors to take back the property

and expend no more of the shareholders' money. The vendors had taken most of their purchase price in shares of the company and, in fact, exercise the control. They hold 165,000 shares, while the English subscribers hold 90,000, on which only 10s. per £1 share has been called up. If the company went into liquidation the uncalled capital as well as the funds in hand would have to be distributed equally among all the shoreholders, including the vendors, which, of course, would be an injustice, if the vendors had had any idea that the properties were not what they claimed to be when the deal was carried through. In order to prevent the money being wasted or divided among the vendors, the subscribers who bought the shares are taking steps to prevent such a liquidation, and are pushing the vendors pretty hard in order to get them to accept a more reasonable proposition. Probably in the end some compromise will be adopted, and the more violent means of alleging fraud in a court of law will not be resorted to.

DENVER, COLORADO.

Activity at Leadville.—The San Juan Region.—Output of Cripple Creek.—New Reduction Works.—Attempt to Kill Bulkley Wells.

An attempt was made to kill Bulkley Wells, the manager of the Smuggler-Union mine. It happened in the very house in which Arthur L. Collins was so brutally assassinated in 1902. At 2 o'clock on the morning of March 28, a charge of dynamite was set off under Mr. Wells' bed. There is no question but that it was dynamite, as no remnant of a containing vessel was found, and the explosion was severe enough to tear a large hole in the floor, wreck the bed, and blow out window-lights in adjoining rooms, although the room in which the explosion occurred was open on two sides, being protected merely by wire screen. About half a dozen sticks of dynamite must have been used. Whoever placed the powder obtained access to the room by forcing a bathroom window on the same floor and entering it by means of a ladder. This was done about midnight or a short time afterward, as it had been snowing during the evening, but stopped a few minutes after midnight. The ladder was thrown to one side, and had a slight film of snow on it. The powder was evidently placed by one familiar with the place, with Mr. Wells' habits, and his whereabouts. He was in town during the evening, and had gone to bed only a few minutes before the explosion. These facts indicate a timing device, but no evidence of any could be found. Undoubtedly what saved Mr. Wells' life was the heavy mattress he was sleeping on, and the open sides to the room. He was thrown to the ceiling, but suffers only from shock and various bruises and minor cuts. The would-be assassin is as yet unknown. The motive given greatest credence is that Wells is the principal witness for the prosecution of Stephen Adams, for the murder of Arthur L. Collins. The trial is set for May 12, and it is supposed that the Western Federation wants to get Wells out of the way. Agents of the Federation are at present in the county trying to get expressions of opinion from men whose names are on the jury list, as a basis for a change of venue. It would also help their case to have local citizens attempt violence, as well. Should Adams be lynched, he and his secrets would not longer menace the Federation. Mr. Wells was a witness in the trial of Haywood and Pettibone at Boise. He has always been fearless in his opposition to the anarchists who have committed so many unpunished crimes in Colorado, and he incurred their hatred first by organizing a military company at Telluride and then by becoming Adjutant-General of the State militia, taking a prominent part in the troubles at Cripple Creek.

The strike of the Denver & Rio Grande shop employees continues. Numerous attempts have been made to arbitrate the points at issue, but without success. The railroad management adheres strictly to its first proposition, namely, that it will operate its shops under the 'open' policy and no other.——The citizens of Leadville have organized an association and appointed a committee to revive the interest in prospecting and developing new territory surrounding this famous camp. It would seem an opportune time to arouse interest in this district, so notable through its long and steady output, and especially in view of the recent gold discoveries in the outlying districts. The Dinero adit under Sugarloaf mountain is passing a heavy flow of water, and the old shaft workings, 600 ft. overhead, will be open to inspection very soon. Work has been resumed at the Highland Chief, which was closed last November. Emil Vernier and Robert Shipley are the lessees. Two new tunnel projects are to be started as soon as the weather permits; one is to start from Colorado gulch with the object of cutting the Tiger Shields and Venture lodes. The other adit starts in Gleason gulch, in the St. Kelvin district, and is to extend to a point under the old Berdella shaft, a distance of 4000 ft. The St. Kelvin Mining & Tunnel Co. has been organized recently to carry on this project.

The San Juan region is becoming active earlier than usual. The St. Paul Mining & Milling Co. has been incorporated, with a capitalization of $100,000, to operate the St. Paul mine, which was once a rich producer, in the Red Mountain district, near Silverton. At Telluride, the Smuggler-Union Co. is gradually increasing its working force as desirable miners apply, and the Lewis mine in Bridal Veil basin is being unwatered by lessees preparatory to making a test-

The Smuggler-Union Mill.—The House to the Extreme Left is the One in Which Arthur L. Collins was Assassinated and in Which Bulkley Wells was Attacked.

run at the mill. The T. M. C. tunnel, north of Lake City, is advancing again. The work is being done by hand. On Henson creek, in the same locality, work has been resumed on the California tunnel.

The output for March from Cripple Creek was not quite as large as it would have been had transportation facilities been adequate. This has affected the small producers and dump lessees most, but as their output is of lower grade for the most part, the total value shipped for the month will not be seriously affected. The Stratton's Independence cyanide mill has been completed and tested until perfectly satisfactory results have been obtained. This mill was designed by Philip Argall. It is up to date in every respect, employing the best features in American and foreign practice. The capacity of the mill is 6500 tons per month. Only low-grade oxidized ore from the Stratton's Independence dump and mine will be treated. Work on the Trilby mill is being pushed as rapidly as possible. Most of the machinery is in place. This plant has a Pearce roaster for treating the unoxidized ore from the mine. The Rocky Mountain smelter, at Florence, which was purchased three months ago by the Troy Consolidated Mining Co., is being thoroughly remodeled, and the roasters are being rebuilt. The company owns claims at Cripple Creek, and will treat custom ore as well as its own. Progress on the drainage adit has averaged 9 ft. per day for the past two months, with two shifts, and three shifts are now being tried in an endeavor to make a record.

SALT LAKE, UTAH.

Resumption of Work. — New Enterprises. — Utah Consolidated Smelter. — Daly West Report. — Boston Consolidated.

The Boston-Sunshine Gold Mining Co. has been organized to operate the Sunshine mine in the Camp Floyd district. The property is equipped with a good milling plant and a slime department is to be added without delay. A. W. Chesterton of Boston, one of the directors of the Consolidated Mercur Gold Mines Co., is president.——The May Day mine in the Tintic district will return to the list of producing mines this week, after having been closed down since the beginning of the year on account of the low metal market. It is expected that several other properties that have been inactive for some time will re-open during the present month. In May others will follow, as the Tintic Smelting Co. will shortly be ready to receive custom ore.

A special meeting of shareholders of the Ohio Kentucky Consolidated has been called for April 6, at which time the matter of increasing the capital stock will come up for consideration. This company is operating in the Ploche district, but Salt Lake is the headquarters.——The capital stock of the Federal Ely Mining Co. has been made assessable at a special meeting of shareholders, and the directors have authorized a levy of 5 cents per share. This company owns some valuable mining property and water-rights in the Ely district, Nevada.

The Utah Consolidated is going to commence the construction of its proposed new smelter in Tooele county. The announcement has been made that all the options and smoke easements on lands required have been obtained, and therefore nothing stands in the way of the company going ahead to erect a plant to take the place of the one near Murray which was forced out of business through unfavorable court decisions resulting from the trial of the smelter-smoke cases. The Utah Consolidated has purchased outright 1200 acres of land in the vicinity of the smelter site, which is in Pine canyon four miles above the town of Tooele and 15,000 ft. from the company's mines at Bingham. The mine and smelter are to be connected with an aerial tramway. It is planned to operate an electric trolley road between the smelter and the town of Tooele, where employees of the company will make their homes. The company will own and control about 21,000 acres, all within a radius of five miles of the smelter. A unique plan has been hit upon to avoid trouble in the future. The valuation of the lands optioned to the company having been fixed, owners are paid 10% of the stipulated value per acre in cash. In case damage accrues through the operation of the smelter, the company agrees to take up the option and accept a deed. If the land-owner sees that he has suffered no damage or prefers to keep his property, he can do so; but the cash received from the company is retained.

The annual report of the Daly West Mining Co. has been issued to shareholders, and covers the operations at Park City during 1907. The exhibit shows that 24,856 dry tons of crude ore, concentrate, and miscellaneous ore was sold during the period stated, the same bringing $771,679; the sum representing the total valuation of 8,086,456 lb. lead, 949.91 oz. gold, 1,042,062 oz. silver, and 5,111,060 lb. zinc produced. The crude ore averaged 43.13 oz. silver, 0.04 oz. gold, 13.43% lead, 1.4% copper, 7.8% zinc; selling at $28.51 per ton. The concentrate averaged 54.54 oz. silver, 0.04 oz. gold, 28.15% lead, 1.53% copper, 15.4% zinc; selling at $48.85 per ton. The miscellaneous ore, which came mostly from lessees, averaged 30.10 oz. silver, 0.032 oz. gold, 9% lead, 1.14% copper, 8.2% zinc; selling at $18.33 per ton. On account of labor troubles the mine was closed down from Sept. 25 to Nov. 15. Since the incorporation of the Daly West company in 1892, there has been produced from the mine 13,467,032 lb. copper, 84,893 tons lead, 16,113 oz. gold, 19,591,822 oz. silver, and the receipts from the sale of this product were $11,975,099.

Samuel Newhouse assures Boston Consolidated shareholders that there is no ground for anxiety. A change in the method of mining has hindered production, but this is to be remedied within 90 days. The new mill is doing well, even under adverse conditions, and is making a saving of 66%. Mr. Newhouse has made an offer to put up his property at Salt Lake against Boston Con. stock at $15 per share, as proof of his sincerity.

MEXICO.

El Oro.—The Hostotipaquillo District.—Mololoa and El Favor.—The Mitchell Co.—General Revival in Mexican Mining.

In the State of Jalisco the country about Hostotipaquillo, north from Etzatlan, is rapidly coming to the front and foreign capital is being invested, encouraged by the great amount of work being done out from Orendain (25 miles west of Guadalajara on the Mexican Central Railroad) by the Southern Pacific line to Guaymas, which line must pass near the Hostotipaquillo district. The Virginia-Mexico Co., with large holdings in this district, successfully weathered the financial storm, met its payments when due, is now transporting from Etzatlan the machinery for a 30-stamp battery, two tube-mills, Wilfley tables, and cyanide vats, and has ordered some 300 hp. of electrical equipment. The Casadas Co. has unwatered that property and has verified the old data, to the effect that the 'ancients' were working in rich ore when driven out by the water. A fine body of ore has been encountered in the bottom, and the character of it is such as to indicate that the workings are on the northern extension of the old Mololoa-El Favor vein, so that now work is to be started on a new and permanent working shaft. Canadian and English capital has bought for $80,000 gold the Mololoa, which, with the exception of the Albaradon, is about all that remains unsold of the large holdings obtained by Carlos Romero, at ₱500,000 from the estate of De la Parra, in Guadalajara, a year ago last fall. The Mololoa is a splendid old property and should open up with proper development, which will be directed by Frank G. Stevens, formerly in charge of El Favor for the Makeever Bros. For El Favor it was claimed that over ₱8,000,000 worth of ore was blocked out in one year's development work, and that ₱88,000 worth was shipped without stoping. The property is now said to have over 300,000 tons of ore blocked out that will average above ₱30 per ton, and it is reported that an English company has just obtained the property under a bond for ₱4,000,000. Whether it is the same company that has taken over the Mololoa above mentioned has not yet been ascertained. W. R. Ramsdall, president of the Casados and Tenemache M. companies, and vice-president of the El Favor Co., who has been the leading promoter in most of the large Hostotipaquillo deals, has obtained control of the Expectativa mine, 10 miles southwest of Ameca, at the rate of $200,000 for the whole, and will at once organize a company for its proper development. The aerial tram and 40-stamp (150 ton) concentrating and cyaniding plant of the Amparo Co. of Etzatlan, built and completed last fall after the results of the experimental plant placed at the mine in 1905, had been seriously damaged by the caving of some of the foundations, but it is expected to have the mill in working order again in a few months.

Ever since the coming to Mexico a month or so ago of Walter Harvey Weed and W. H. Stevens there have been persistent rumors to the effect that the Tennessee Copper Co., with which they are both associated, was seeking investment in Mexico, but nothing could be learned further than that it was probably in the Balsas River district of Guerrero. Now it is definitely understood that Messrs. Weed and Stevens have made a complete examination and thoroughly sampled the La Dicha properties of the Mitchell Co. in Guerrero, and that for this purpose the workings were all unwatered, under the directions of E. E. Noon, who has for some years been the superintendent at La Dicha, and was present during the examination. Messrs. Weed and Stevens have returned to the States and undoubtedly the results of their examinations will soon be made public, while in the meantime Mr. Noon is awaiting orders. It is certainly to be hoped that as sensible and practical a company as the Tennessee Copper is known to be, may take hold of this La Dicha property, which, it is believed,

under proper management should develop into a highly profitable enterprise. And nothing could be more beneficial for the State, for there are many mineralized belts throughout Guerrero to attract capital, once it is directed that way. The mere fact that this examination has been made, following so closely upon that of the Chihuahua and the Potosi companies of Santa Eulalia, Chihuahua, by Chas. M. Schwab and associates, cannot but help have its tonic effect upon the conditions of the mining industry in general throughout the Mexican Republic. As yet nothing has been heard regarding the Chihuahua and Potosi deal, but if "silence is golden," it will take quite a lot of it at just this time to get together the $8,000,000 which are said to figure in the Chihuahua-Potosi transaction, and it may be some little time before we hear any more noise. In the meantime these properties continue their production of some 400 tons per day.

There is no doubt but that throughout the entire Re-

Western Australia.

public mining interests are recovering from the set-back of last fall. A number of mill and small reduction plants are in course of construction, and the properties that have mills in running order are greatly increasing their production, as are also those that ship direct to the smelter. And even the copper properties that closed down because of the drop in that metal are finding that they have ore that can be shipped even under present conditions. The Government is doing all in its power to encourage a more bopeful feeling at this time by postponing until July 1 the inauguration of the new freight rates on ores. This, it will be remembered, was in effect a re-classification of ores into three heads: those of less than ₱25 valuation, those between ₱25 and ₱50 valuation, and those over ₱50 valuation per metric ton, and a general increase in the freight rates of practically 10%, 20%, and 30% respectively in the three classes. This was a great reduction from the rates which the railroads had wished to put in force, but had been decided upon as a kind of compromise and was to go into effect on April 1. Representatives of mining and smelting interests have shown the Government how unwise it would be to put this additional burden upon the mines at this time, and it is generally believed that the Government will hold the new rates back until July 1, at least.

KALGOORLIE.

Production Declining.—Important Discovery in the Great Boulder.—Filtering Devices.—Methods in Use.

The current year opened with mining generally on the down grade. Our mines are extracting big tonnages, but the assay-value is lower and consequently profits are suffering, in the majority of cases.

In 1907 the gold yield of Western Australia was valued at $36,000,000, against $38,000,000 in 1906; of this Kalgoorlie produced fully $19,000,000. The dividends paid last year totaled $8,500,000, against $9,800,000 in 1906; while the mint at Perth dealt with bullion valued at $26,500,000, against $26,000,000 the previous year. Its annual capacity is about double these amounts.

The ore reserves in most of our mines are fairly large, but the grade is lowered every year; and while poorer ore is encountered in some, it is of interest to know that in the Golden Horseshoe, Ivanhoe, Kalgurli, and especially the Great Boulder mines, the deeper workings show good ore.

During the past week two most interesting and important developments were announced from the Great Boulder. The first referred to diamond-drilling at the 1000-ft. level; a vein was cut 12 ft. wide, assaying $45 per ton; but the finest development this district has seen for some time was that at the 2200-ft. level, where they had driven on the main lode between the Main and Edwards shafts for 300 ft. in ore assaying $29 per ton for 5 ft. wide, while the present face is worth $70 per ton. The following are the published ore reserves on December 31, 1907:

	Tons.	Yield per ton.	Profit per share
Associated Northern	141,181	$13.00	$2.50
Great Boulder	650,870	18.00	4.00
Golden Horseshoe	1,062,322	13.00	15.00
Kalgurli	650,000	14.00	27.50
South Kalgurli	111,039	7.50	0.50
Perseverance	461,598	7.50	0.50

Profit per share is obtained by deducting from total value of reserves every possible expense, including the loss in residue. On several of the smaller mines, on the fringe of the Golden Mile, a good deal of work is being done in the oxidized portions by parties of tributers, who are doing fairly well on the average. They pay a royalty on gold won as usual.

As regards the treatment of ore here, there is little change. The Ridgway plant of 10 machines at the Great Boulder is working fairly satisfactorily. At the Lake View Consols a Cassel plant is being erected to treat the residue-dump, which contains well over 500,000 tons. A Cassel or Butters plant treating 150 tons daily of oxidized slime is doing good work on the Croesus mine. The Sons of Gwalia, one of the large mines in the interior of the State, has also a plant of the same design at work, but whether on old slime or fresh battery slime, I do not know. Apart from these departures, the filter-press still holds its own on the treatment of both roasted and unroasted ores in this district.

The Associated, Kalgurli, and Perseverance use dry crushing, roasting, grinding-pans, and filter-presses. The Lake View Consols and the Oroya-Brownhill employ wet crushing, concentration, pans and tube-mills, bromo-cyaniding, and filter-pressing. The Ivanhoe, Golden Horseshoe, and Hainault use wet crushing, concentration, pans and tubes, sand-treatment in vats, and filter-pressing of slime. At the Great Boulder the Ridgway machines are treating the old slime-dumps containing hundreds of thousands of tons, worth about $2.50 per ton. Presses are at work on the mill-product.

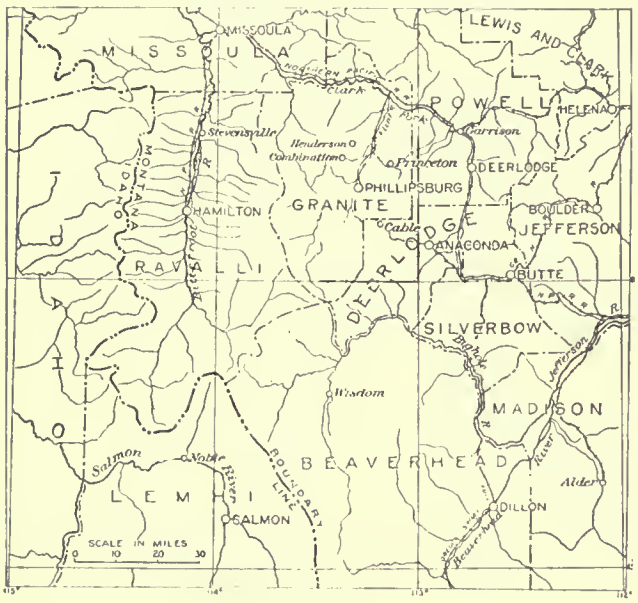
BUTTE, MONTANA.

Copper Production in March. — Resumption of Work. — The Fire Underground.—East Butte.—Gold Discovery.

In March the Butte mines produced 18,127,250 lb. copper from 584,750 tons of ore, the different companies contributing as follows:

	Tons of ore.	Pounds of copper.
Boston & Montana	210,000	6,510,000
Anaconda	162,500	5,037,500
Butte & Boston	18,600	576,600
Washoe	18,900	585,900
Parrot	4,000	124,000
Trenton	9,000	279,000
North Butte	80,000	2,480,000
Butte Coalition	32,000	992,000
Original	38,500	1,193,500
Miscellaneous	11,250	348,750
Totals	584,750	18,127,250

The Parrot and Neversweat mines of the Amalgamated are still closed, but all the other producing mines of the district are being operated again, and some of them at their



Montana.

normal capacity. The North Butte was the first to reach that stage, and is now shipping about 1300 tons of ore per day to the Washoe smelter at Anaconda. The Butte Coalition is still confining its work to the Rarus mine and is mining 900 to 1000 tons of ore per day, much of it first class. Three levels of the Rarus mine are all in first-class ore, and new orebodies are being opened in the Minnie Healy. Shortly, the latter property will be mined again, but the work will be carried on through the Tramway shaft, owned jointly by the Coalition and Butte & Boston, which is now 1400 ft. deep, at which level and at the 1300 connections are being made with the Minnie Healy. The operations in the latter will be below the fire, and will not be interfered with by gas or fire.

Gas arising from the fire in the West Colusa, Leonard, and Minnie Healy mines again drove out the miners last week, and some experienced men who have been working near the fire say the companies never will be able to extinguish it, and that the only thing they can do is to restrict it and get it under control, as the Anaconda Co. had to do with the fire in the St. Lawrence mine, which has been burning since 1889. While the fire in the St. Lawrence makes the mine very hot and uncomfortable in some portions, it does not otherwise interfere with mining, as it is completely walled in with a wall of cement, and is confined to its original limits. That will probably have to be done with the fire in the Coalition and Boston & Montana mines. In the Minnie Healy the fire is confined to old stopes on the upper levels and will not interfere with work on the lower levels through the Tramway shaft, but the gas arising from the fire has repeatedly driven miners out of the Boston & Montana mines and has prevented much work in the Minnie Healy. The Boston & Montana Co. is doing nearly all the work of fighting the fire. It is engaged in sinking three or four shafts for the sole purpose of creating a draft and ventilation, and get at the fire with water.

Notwithstanding statements to the contrary, the lessees in the East Butte mines are confined in their mining to the 400 ft. level and the levels above that. No mining has been done below the 400, but some good orebodies have been opened by the company on several levels down to the 900 ft. station, containing a large quantity of first-class ore. Recent developments in the property have disclosed the fact that large orebodies are known to exist at depths that have not yet been opened by the East Butte, but were known by the Butte & Boston Co. years ago, before it became a part of the Amalgamated. There is no doubt that the East Butte when it is able to resume sinking and development work, will develop into an important producing company.

A rich strike of gold quartz has been made in the old Highland district, south of Butte. Samples sent to Butte for assay gave returns of $1750 per ton, and the owners claim the sample was not picked. The mine was located a few months ago by William Waugh, Charles Barnaman, C. V. Franzman, and George Chicaine. The ore was found in a vein at a depth of 50 ft. in a shaft, and has not been opened to any extent. The rich streak is 18 inches wide.

ROSSLAND, BRITISH COLUMBIA.

Increasing Gold Output.—Ore Shipments.—Granby Breaking Records.

In consequence of the increased quantity of gold in the ore shipped to the Trail smelter from the Consolidated mines here, that plant has just been enabled to ship the richest car of matte that was ever sent out of British Columbia. This car was forwarded to the Tacoma refinery and was valued at over $32,000. The matte contained 41% copper, 35 oz. silver, and 45 oz. gold per ton.——The Consolidated mines here intend to increase their output another 100 tons per day.——Development on the gold-bearing ore on the lower level of the Le Roi continues to give gratifying results.——Several more of the claims that have lain idle for years have been leased, and a number of locations on the southern edge of the ancient plug of gabbro, on which Rossland is built, which in years gone by had been allowed to lapse, have been renewed. It is doubtful whether this leasing will add to the local mining industry or not. There is little doubt that many of the leases will be thrown up after a small amount of work is done.——The following shipments were made for the week ended March 21, and for the year to date:

Centre Star	3,270	39,418
Le Roi	1,865	20,094
Le Roi No. 2	665	7,578
Evening Star	35	356
Giant-California	....	60
Total	5,835	67,506

The Granby Consolidated is still working under high pressure and surpassing records. For the week under review, ending March 21, they shipped 25,388 tons, making 219,975 for the year. The smelter treated 23,999 tons, and 215,992 for the year. On the 18th they shipped 4,048 tons, which was a record shipment. Each of the eight furnaces were treating 428 tons daily, forcing them to the very limit of capacity.——The Provincial Government will not permit the city of Greenwood to issue the $50,000 in bonds to bonus the proposed adit.——The B. C. Copper Co. has placed an order for eight 30-ton slag-pots, which will be installed before the resumption of work.——Providence 6% gold bonds to the extent of $50,000 have been placed, and work will now be resumed.——The new organization that is assuming the affairs of the Ymir mine are said to have sufficient funds on hand to do the necessary development work on that property. Funds for development is what

they have needed at Ymir right along.——Spokane men are going to dredge for gold at the confluence of the Columbia and Pend d'Oreille rivers. The company has just been organized.——An assessment of 7 c. per share will have to be levied to clear up the indebtedness of the Sullivan Mining Co. The debt is $50,000, and the outstanding bonds amount to $225,000. The assets are a smelter valued at $500,000 and the mine with 150,000 tons of ore that should carry 15% lead and 6½ oz. silver. The meeting of the minority shareholders was not held.——Shipments through Kaslo for February amounted to 935 tons, over half of which was zinc concentrate from the Whitewater Deep and Ruth mines.

YERINGTON, NEVADA.

Copper Mines. — The Bluestone. — Method of Treatment. — Mason Valley Mines. — The Nevada-Douglas. — Rockland. — Mountain View.—The Wabuska Mine.

The Bluestone Mining & Smelting Co., controlled by Capt. J. R. De Lamar, has thoroughly opened its Bluestone mine near Yerington. C. A. Weck, the manager, estimates that there are three million tons of ore available, running about 3% copper. This estimated tonnage of ore has been exposed by 8000 ft. of work, the main haulage level being a cross-cut that goes in 1200 ft., cutting through a body of ore 300 ft. wide and 500 ft. long. This level cuts the ore 300 ft. below the apex of the lode. A winze is also being sunk from this level in ore. The strike of the orebody is north, with a dip to the east. Lying west of the lode is 100 ft. of limestone, the latter being bounded on the west by granite. Before reaching the ore the main level, which was driven westerly, cuts through 600 ft. of volcanic rock. The ore is mainly a chalcopyrite, in a lime and epidote gangue, there being no oxides nor carbonates even at the outcrop. A 25-drill air-compressor is being installed at the entrance to the main adit, to be electrically driven. Mr. Weck has been experimenting for two years on methods of ore treatment and seems well satisfied with the work now being performed at the experimental plant. With crusher and rolls he pulverizes the ore to 8 mesh and then gives it a slight roast in a tower roaster to magnetize the pyrite. The roasted ore is then passed through a Wetherill magnetic separator, which takes up the mineral and discharges the waste. This product is a concentrate that will run 15% copper, which is to be smelted in the usual way. The ore is uniform in character and seems well suited to this kind of a concentration process. The fact that the epidote gangue is nearly as heavy as the pyrite would doubtless preclude successful wet concentration. While no announcement is made as to the erection of a large plant of the kind now being used on a small scale, it is to be presumed that such a plant will be built eventually.

The property of the Mason Valley Mines Co. lies to the south of the Bluestone, there being one or two intervening claims. The Mason Valley is likewise opened by adit-levels from the eastern slope of the range. The property is controlled by the Gunn-Thompson Co., of which Llewellyn Humphreys is consulting engineer, O. E. Cole being superintendent. The old workings were near the apex, but the principal base of operations now is on a 675-ft. cross-cut, which intersects an orebody 40 to 50 ft. wide in massive limestone. This ore is a heavy copper-iron sulphide in a garnetized lime gangue. A winze was sunk from this level, not on the principal orebody, but on the contact of lime and shale, and from it a cross-cut was driven into the main lode. At the entrance to the principal cross-cut is an electrically driven air-compressor and a blacksmith-shop. A cross-cut is being driven 150 ft. below this one, to cut the same lode. It is now in 200 ft. and must be driven 1000 ft. farther to cut the ore. A third cross-cut gets into ore 150 ft., at 175 ft. vertically above the main cross-cut. This and other properties in Yerington district get their power from the lines of the Truckee Power Co., whose plant on the Truckee is 95 miles distant. A great deal of work on the Mason Valley is projected for performance this year. The ore runs from 3 to 10%, much of it averaging 6% copper.——The Malachite, McConnell, and Western Nevada occupy holdings on the same copper belt as that of the Bluestone and Mason Valley, but farther south. Some work is in progress on these properties also.

The Nevada-Douglas Copper Co. owns a group of mining properties on the western slope of the Yerington range, facing Smith valley. Its holdings take in one mile of a well defined copper belt that strikes north-south, paralleling that on which the Bluestone and Mason Valley mines are located. It includes the original Nevada-Douglas and Ludwig mines. The principal vein is a quartz fissure within the limestone, but the ore also spreads into the lime, forming an irregular orebody. The vein has a dip of 45° east, which is slightly greater than that of the regular stratification. The vein-filling consists of a silicious gangue, carrying cupriferous iron pyrite and copper oxides. The oxides and carbonates extend from the surface to the 500-ft. level. The carbonates follow the dip of the main fissure, but are mostly outside of it in the limestone foot-wall, the fissure material being a gossan, carrying fair ore. Just below the 500-ft. level the sulphide ore gradually comes in, that being the water-level. Small bodies of porphyry intrude into the orebody at various points. On the contact of the lime with these porphyritic intrusions occur some of the richest shoots. In some of the oxidized stopes the ore carries 20 and 25% copper, the average being 12%. The ore in the gossan is said to average 5% copper. In the sulphide stopes are bodies of chalcopyrite, chalcocite, and bornite, running from 7 to 26%, these being in the vein proper. In the adjoining shale the pyrite assays 2% copper. The width of the ore in the sulphide portion is 50 ft. in some places. The oxidized ore in the upper levels runs from 15 to 150 ft. in width. A vertical shaft on the Ludwig has been sunk to 400 ft.; from the bottom station a 160-ft. cross-cut runs to the vein, where an air-hoist is stationed, by which a skip is operated on a 280-ft. winze that follows the dip of the vein. It is planned to raise from the head of this incline 460 ft. to the surface and make it the principal shaft for hoisting ore. At present six air-drills are operating in the mine, mostly in the sulphide orebodies. The air-compressor is at the mouth of the Douglas adit, 3500 ft. from the main shaft. This Douglas adit is in 650 ft., and when driven farther it will cut the orebody at a vertical depth of 600 ft. In driving this, thus far an 18-ft. vein of 5% copper has been intersected. W. C. Orem of Salt Lake is general manager, with S. S. Arentz as local manager. The latter states that there are 8000 ft. of work on the group. The water-supply for the property is conveyed from arteslan wells in Smith valley by a 17,000-ft. pipe-line.

The Nevada-Rockland Co., whose mine and mill are situated 26 miles south of Yerington, has not been operating the property for five months, but work may be resumed this spring, as E. A. Parberry, the superintendent, is on the ground now. The mine is well developed by adits, levels, and winzes. From the lowest level to the apex is 600 ft. vertically. The vein is 4 ft. wide, between rhyolite and diorite walls; the ore consists of chert and quartz, carrying gold. The mill was equipped for dry-crushing and cyaniding. The ore is said to average $11 per ton.

At Yerington much interest is taken in the Mountain View and contiguous properties, situated in the Walker range, which separates Mason valley from Walker lake. The Mountain View belongs to the Wilson Gold Mines Co., of Yerington. The claims are 14 miles east of this town and 6 to 8 miles from Schurz. The property covers a gold-bearing lode that strikes through the Walker range from west to east. The outcropping ore averaged $6.20 per ton, and at greater depth samples assayed from $10 to $100 per ton. Several hundred feet of work has been performed.

The Wabuska Copper Co., managed by J. E. McDermott, has 20 mining claims 16 miles from Yerington and 5 miles from Buckskin. Work at 120 ft. depth shows a 20-ft. lode of copper sulphide ore. The lode is on a contact of limestone and porphyry. The ore varies from 1 to 30% copper. The company is planning to install an air-compressor and a gasoline hoist, and then sink to water-level.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Track-laying on standard gauge roads costs $250 to $300 per mile under fair conditions.

Cemented gravel weighs about 133 lb. per cu. ft. For large blasts, about 15 lb. of powder should be used per 1000 cu. ft. of gravel, measured in front and above the lateral drift.

Helmets such as are made for rescue service in mine fires are not trustworthy, and are good only for short periods of time. As built they are too cumbersome and hinder the vision of the wearer.

Wooden trestles for standard gauge railroad tracks cost from $9 to $10 per lin. ft. of track for trestles 15 ft. high, with 25 c. per lin. ft. for each additional foot of height, if timber costs $50 per 1000 ft. on the ground.

The horse-power transmitted by single leather belts equals the breadth in inches multiplied by the speed in feet per minute multiplied by 70 divided by 33,000. The results should be multiplied by 1.5 for double leather belts.

Electricity has found many new applications in the refining of metals. The use of the refining furnace for copper and lead is being replaced by electrolytic processes, which have done much to facilitate the recovery of small quantities of gold and silver.

In concrete work large stones may be used in many cases to economize material. These should be cleaned and laid so that no spaces are left beneath them. They prevent cracking, and are economical in engine beds and other massive foundations.

The temperature necessary for cupellation of lead buttons not containing appreciable quantities of copper or iron, is 800°C, but 850°C is necessary to start the cupellation. This temperature can be reduced to 770°C during the oxidation of the greater part of the lead.

Sand, as a mining term in use in the Lake Superior country, refers to the layers of Glacial sand that cover the deposits of iron ore in that region. Sometimes it is a quicksand and, on account of the large superficial area of the iron deposits, this sand follows the mining operations to a considerable depth.

In the treatment of asphyxiation by carbonic acid gas, fresh air is the most important agent. As soon as the first symptoms appear, the men should be brought to the surface, and if still breathing, little treatment will be necessary. If breathing is suspended, artificial respiration must be resorted to, and a few whiffs of ammonia will assist in stimulating it. Usually two or three minutes suffice to produce regular breathing. If a great deal of nausea is present, an emetic is useful. Cold bandages wrapped around the head, or bromides in the worst cases, will remove the headache which often results from the inhalation of gas.

Reliz is used among the Mexicans at El Oro as the equivalent for the hanging wall of a vein. In Sinaloa this term is applied to 'slips'; for the enclosing plane they use *tabla*. The Spanish language permits of nice distinctions: as *huellas* for tracks of hoofed animals and *rastros* for men's tracks; also *pies* for human feet and *patos* for animal's.

Igneous rocks may be classified from a chemical point of view in three ways. The ultimate composition, or the approximate units, that is, the minerals contained may form the basis for classification. Lastly, the magma may be considered a solution and the eutectic mixtures as the definite types with which the igneous rocks shall be compared.

Gravel or sand used for concrete should be free from mud and clay. It should be tested by stirring a known weight in water and finding the percentage that will settle in a limited time. Slag is often used for construction at copper smelters, and is satisfactory. Some is granulated to replace sand, and some can be crushed to replace gravel or stone.

Employment of aluminum, in quantities as low as 0.01%, to prevent blisters and fissures in steel ingots gives excellent results. Suppression of blisters is due to the fact that aluminum has so great an affinity for oxygen that when it is thrown into a crucible of melted steel it absorbs all the oxygen, free or combined with iron, disengaging such heat that the metal is extremely fluid.

The gravity stamp was invented by Von Maltitz about the year 1505, but the first commercial use of it was made by P. Gromstetter in 1519, when he established at Joachimsthal a process of wet stamping and sifting. Until the nineteenth century the stamp was merely a square timber with an iron shoe on the bottom. The discovery and development of the Comstock revolutionized milling practice.

The origin of petroleum is still open to question. It is probably the result of fractional distillation of long-buried plants and animals gradually emitted during decomposition or gentle distillation. It has also been suggested that there may be zones of metallic carbides in the earth, to which waters charged with carbonic acid and atmospheric air have penetrated. This theory is, however, in conflict with the assured physical condition of the earth's interior.

Excessive contraction of the earth's crust first doubles the strata together, then pushes the compressed fold over its side, and finally forces the crumpled mass along above the beds lying beyond the folded area, leaving older ones stranded on the later deposits. In the southern Appalachians, the overthrusts have carried the beds as much as five miles from their starting points, and subsequent erosions have destroyed any visible connection.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Capitalizing Equipment.

The Editor:

Sir—The report of the Mysore Gold Mining Company for the year 1907, which has just been published, contains an announcement of no little importance in connection with the system of finance adopted by John Taylor & Sons. This firm has of course always proceeded on the best possible lines of financial management and accounting laid down by leading bankers, accountants, and lawyers. The system was to charge expenditure on important new works to capital. For instance, if a new shaft was to be sunk or a new stamp-mill or cyanide plant provided, the money was not drawn from revenue, but the shareholders were asked to subscribe for new shares. Thus the capital of the Indian mines was being continually increased, and concurrently handsome dividends were being paid. For instance, a profit of a quarter of a million pounds might be distributed as dividends and at the same time the shareholders were being asked to subscribe £100,000 of new capital. I referred to this matter in another place a few years ago, and my articles were printed in 'Economics of Mining,' but it is worth while referring to the subject again. When a company is not paying its way, everything is capital expenditure, and when a company is paying to a certain extent, any additional expenditure on extensions with a view to putting the property on a sound basis is properly placed to capital expenditure. The English accountants have usually carried this principle further and held that all subsequent expenditure of this sort was rightly and logically charged to capital, although the profits were more than ample to provide the funds. Apart from the logic of the thing, the method is attractive to directors because it makes the rate of dividends look bigger. The shareholders and the stockbrokers also like it, for it makes it possible to place the capital value of the shares at a higher figure. Apparently nobody ever thinks, while the capital of the company is mounting up, that a time will come when the capital will either hang as a millstone round the neck of the company by increasing its obligations, or suddenly become extinguished by the exhaustion of the mine. A more modern school of thought has recently sprung up in many quarters (and I am here referring not to mining companies alone, but to all classes of industrial organizations), and capital commitments are discouraged wherever possible. Now, in this matter, as in others, a pound of practice is worth a ton of principles, and the stress of circumstances is often strong enough to alter principles when argument and scientific reasonings fail. Several large firms in London during the bad times of recent years, have had to find additional funds without asking the shareholders to subscribe for new shares, simply because the shareholders have not had any available money at their command. Consequently, new improvements and extensions in paying mining companies are nowadays more and more paid for out of revenue. To get back to the case of the Mysore Mine, it is specially interesting to find so eminent a firm as John Taylor & Sons adopting the modern principle. In April, 1906, the shareholders of the Mysore company were asked to subscribe for 30,000 additional shares at £6 each, leaving 3968 unissued. This result has caused the directors to decide to charge all expenditure to revenue in future. The average expenditure on capital account during the past eleven years has been about £60,000 a year, and the directors estimate that this rate is likely to be continued. Seeing that the annual profits are about £400,000 a year, this alteration in financial arrangement will not make an alarming difference in the dividend.

During the year 1907, the amount of ore milled was 194,838 long tons, producing 186,333 oz. of bullion. The cyanide plant treated 167,529 tons of tailing, producing 23,108 oz. bullion. The total extraction was 209,441 oz. bullion, equal to 210,909 oz. standard gold. The total income, after deducting £40,644 royalty, was £786,652. The costs charged to income were £357,596, and the profit was £429,056. In addition, £79,243 was spent out of the capital subscribed in 1906. The outlook at the mine is most promising, for in many places the ore is developing in large quantities, and the mine has an assured life of many years. Since 1884 the total production has been equal to £9,937,541.

EDWARD WALKER.

London, March 8.

Concerning Promoters.

The Editor:

Sir—In regard to what our Cornish friend, T. A. Arehbold, says concerning the brunt of an unsuccessful mining enterprise falling on the engineer (in your issue of March 7), I am going to differ with him.

It is the promoter that feels the jar; having worked both ends of the line, I think I am competent to speak. Who except the directors and officers know who is running the property, which is miles and miles away from the home office? When the mine shuts down, he gets a letter or two from the general manager, and he has to hunt another place. But not so with the promoter. For instance, I knew a man back East who had put on foot five different mining deals and two oil propositions; none was successful, first from one cause and then another; all over the city I would hear him spoken of as a crook, a grafter, etc. One morning I went into his office, and there was a pile of mail a foot high. I remarked on its size. Upon his request I opened a number of letters; they were all from stockholders of his unfortunate companies; some were pleading for the return of money from widows; some were formal demands "or proceedings would be instituted"; and so the letters ran. He said for years he had been getting them, and told of the distraction and worry that had been his; it was easy to see that the man had a heavier burden than he could well stand under, with no hope of the miserable load being lifted. While we were talk-

ing, a man came in, and of all the insulting remarks and names I ever heard, he gave the owner of that office, and before long I knew he had bought some stock that the promoter had offered. I was told later that once or twice a week the unfortunate man had callers like him. Such is the life of many a "cold-blooded manipulator."

To many the name of 'promoter' means crook or rascal, but that is simply because they are ignorant on the subject. One time a friend walked into my office and asked me for the definition of a promoter; my answer was: "One who gives his friends advice on some investment; if it turns out good, it is no more than right that they should have been told of it, and they in turn tell their friends of their financial genius; but if it goes wrong, they go to all their friends and brand the promoter as a liar, thief, and crook." "No," my friend said, "come to a lighter vein." Then I said: "A promoter is one who will supply the ocean if the 'easy mark' will supply the ships." "No," he said again; "A promoter is a well-dressed individual who wants to sell nothing for something to someone who wants to buy something for nothing."

TOM L. GIBSON.

Silver City, New Mexico, March 16.

Mining Law.

The Editor:

Sir—In your editorial on this subject in the issue of March 14, you say that "only in absolutely new territory, where the miner has made no entry, could a new law be applied." Is not this putting the matter too strenuously? For example, the Apex law was adopted in British Columbia, but as soon as the authorities realized the crop of lawsuits certain to ensue, they repealed this law and substituted the Square Location law. Although there have been some lawsuits over claims located under the Apex law in British Columbia, have there been any serious conflicts resulting from the application of both laws? It is probably true that the number of claims located in British Columbia under the Apex law is not great, but surely it is not too late to introduce the Square Location law into the Territory of Alaska, where the majority of claims located to date are placers.

My understanding is that we already have the Square Location law in the Philippines, and it applies the world over outside of the United States and Alaska except (?) in Rhodesia. Our placer regulations are, to all intents and purposes, the Square Location law. We now locate as placers salt, gypsum, borax, phosphate, oil, and other hydro-carbons, fire-clay, building-stone, roofing-slate, etc., and our Coal Land law is, in effect, of the same character. Moreover, in the Leadville cases, where the lodes are largely in blanket form, the Apex law was, in effect, not applied, as confusion worse confounded would have resulted from its application. Judge Lindley says, in regard to the Leadville cases and blanket veins: "It is hardly profitable to pursue the discussion further. Enough has been said to show the absurdity of the law (Apex law) when applied to geological conditions which were not in contemplation of the law-makers when the laws were enacted."

As blanket veins, folded into synclines and anticlines, and irregular orebodies and lenses, are of frequent occurrence, it is evident that the remarks of Judge Lindley may be applied to many other districts than that of Leadville.

H. W. TURNER.

San Francisco, March 24.

Amalgamation.

The Editor:

Sir—Referring to a discussion by Messrs. C. W. Van Law and E. H. Nutter in your issue of December 14, 1907, I wish to say that "large roomy mortars" are not a bit of good for catching gold that will not amalgamate, as I know from experience; in any case, modern milling does not permit of time to wait until ore is crushed in that class of mortars.

The gold I refer to here was contained in an intense black, friable tourmaline-quartz, assaying 1½ oz. gold. Only 50% of the gold freed by crushing would amalgamate; the other 50%, which was brown in color, positively would not amalgamate. I tried cyanide, also nitric acid, with like results. The gold in question was dissolved out of the tailing after a long period of treatment.

There is really no economic and handy method for the complete separation of unamalgamable gold from the pulp; traps, blanket-strakes, etc., will recover a portion of it; pan-settlers are useless, as too much concentrate gets mixed with the gold. Amalgamating-pans and tube-mills will not recover the gold, but will slime it, and in that condition it will readily dissolve in cyanide, other things being equal. A feature of interest to geologists in connection with the tourmaline vein was that as the mine became deeper the tourmaline gradually gave place to arsenical iron, copper pyrite, and native bismuth, which causes me to think that tourmaline is a secondary mineral.

Sydney, New South Wales, January 25.

Use of a Soldering Iron.

The Editor:

Sir—Some years ago, it fell to my lot to set up a gasoline engine on a mine in Oregon that was isolated from the outside world by over 10 ft. of snow on the intervening divide. When we unpacked the battery cells, we found them all broken. Something had to be done at once. We found some pickle jars in the kitchen, which were promptly confiscated; but when we attempted to cut the tops of them off, by means of a string soaked in kerosene, igniting it and plunging the jar in water, the crack did not always follow the desired course, and we found we would be out of jars before we would have enough of them properly cut for our needs. Necessity prompted another method, which proved successful, and a description of which may be of use to some of your readers similarly situated. We invented a soldering iron, and after heating it and starting a small crack in the mouth of the jar by a gentle tap

with a small file, the point of the hot soldering iron was placed in contact with the glass about one-eighth of an inch in advance of the end of the crack, which slowly extended toward the hot soldering iron. By keeping the latter an eighth of an inch in advance of the crack, it could be led down the side of the jar to the point where it was to be cut off, when its course was changed at a right angle around the jar, and the job was done. By using this method we did not lose a single jar, and I have since used it when necessary to cut a circular plate of glass for a steam gauge, compass, or clock, always starting with a small crack in the edge of the glass. By the way, why is the above mentioned tool called a soldering iron when it is made of copper?

W. H. WASHBURN.

Ballarat, California, March 11.

[A 'soldering iron' was originally a hot iron tool, but copper is now used because the solder will alloy with the copper through the medium of a 'flux,' such as zinc chloride.—EDITOR.]

Accommodations for Employees.

The Editor:

Sir—Doubtless most of your readers are acquainted with mining camps where the men employed bring with them a roll of blankets and are assigned to a bunk-house in which are built rows and tiers of bunks and occupied by many men, allowing absolutely no privacy to the individual. As a matter of fact, a great disregard for the comfort of employees has prevailed in the majority of mining camps.

The tendency on the part of the mining companies for the last few years, however, has been to better the accommodations; as far as the writer knows, no mining company has gone to the length that the Alaska Treadwell Gold Mining Company has in providing for the comfort of its employees.

Anyone entering either of the two new rooming-houses recently completed and now occupied, would think that he was entering a first-class hotel instead of a mine bunk-house. Each building is three stories, attractively painted, with one central entrance in the front on the ground floor, and three entrances, one for each floor, in the rear of the building. You would never think that the men entering the building through the rear entrances on their way from work are the same who emerge a little later, spick and span, from the front door.

The interior of the building is divided into 26 single-bed rooms and 28 double-bed rooms, and is plastered throughout, all woodwork is painted white and the floors are oiled. The single rooms are furnished with an iron bedstead, springs and mattresses, chairs, a table, and a clothes closet. The double rooms have two beds, two clothes closets, a table, and chairs. The building is steam heated and electric lighted. Each floor is provided with porcelain lavatories, hot and cold water, and patent toilets. The very wide halls, lighted from windows at each end and from a central light-well, extend the length of the building, add much to the general appearance of the interior.

The attic is fitted up as a dry-room, and provision made so that the men can leave their dirty shoes and clothes there if they desire. Many of the men avail themselves of the large new dry-room provided with individual lockers, hot and cold water, and facilities for washing; this is situated about 50 yards from the collar of the shaft.

Opposite the main entrance of the building is a large room with chairs and tables answering as a lounging-room. This room is not used much, however, as the club is within a hundred feet, and is provided with reading-rooms, a library, billiard and pool room, bowling alleys, and baths of all kinds, and offers an ideal place for the men to spend their spare time. Each rooming-house is looked after by a janitor, who has a pass-key to each room and keeps them clean, furnishes clean towels, and sees that no malicious disfiguring of the rooms or building occurs.

The management put up these buildings believing that desirable men appreciate good accommodations, and their belief is fully confirmed by the result.

The same care bestowed upon one of the essentials to living, namely, sleeping, has been bestowed upon the other essential—eating. The boarding-house, built near the rooming-house, is a one-story building of a large floor-area and at all times presents a model of cleanliness and neatness. The table provided is the best that the market affords, and will compare favorably with any in the States.

The management takes care of its married employees by providing for them houses at a small rental; these are steam-heated and electric-lighted, and furnished with a bath and other accessories.

E. P. KENNEDY.

Treadwell, Alaska, March 13.

The longest railway tangent in the world is said to be on the line of the Buenos Aires & Pacific railway, in the Argentine Republic. The length of this is 205½ miles, and it is situated on the main line, starting at 158 miles from Buenos Aires. The straight stretch of track was formerly broken by reverse curves forming a detour around Lake Soria; the longer portion was then 175 miles long, and was even then the world's record. The lake having, however, practically dried up, the company has eliminated the curves, and the 'cut-off' was opened to service on October 15, 1907. We are informed by an official of the railway that when the line was located in the '70's (when the country was in the hands of the Indians) after leaving Junin, which was a military outpost and the last point of contact with the Buenos Aires civilization, a course of about west-northwest was set, and the line run straight across the flat 'pampas' until it met another line about 60 miles long, which was pushed out eastward from the western terminus at Villa Mercedes.

There are few industrial schemes which can stand a transplantation from their native territory without undergoing a lengthy process of assimilation and suffering considerable adjustment before evolving to a state of profitableness in a new locality.

Acid-proof cement is made by mixing powdered glass with a concentrated solution of silicate of soda.

MINE ACCOUNTS FOR THE SUPERINTENDENT

Written for the MINING AND SCIENTIFIC PRESS
By ALGERNON DEL MAR.

From time to time we have had different systems of mine accounts, more or less complicated, but very few sets of forms for the mine superintendent's use. I hope others will add or arrange the tabulations according to their own ideas, so that we may arrive at a standard set of forms that any stationer might carry in stock. We are often required to fill out forms with facts that I am sure not one director in a hundred ever looks at or could understand.

In cases where the books are kept at the home office, it were well for the superintendent to keep a set of books at the mine, and duplicates of all statements sent to the secretary of the company.

I take as an example a mine producing about 1500 tons of ore per month. There will be a mine-foreman, mill-foreman, and a cyanide-foreman, all accountable to the superintendent, who alone communicates with the home office. First consider the mine-foreman; his daily report will be very simple. Form No. 1 will cover the facts. A weekly report will cover many more facts, some of which for the first three weeks may be stated approximately, such as powder, fuse, etc., used, but they must be accurate for the full month of four weeks. Form No. 2 is submitted. He must have a time-book, like form No. 3, the letters *A* and *B* referring to the same letters on form No. 2. This may be submitted once a week at the office. The foreman, of course, has a time-check book, which can be very simple, as in form No. 4.

The mill-man will only need a daily report, like form No. 5. The tonnage crushed is generally deter-

mined from the foreman's report of ore delivered at the mill. This, as well as other items, need only be reported once a month. If the mill is a dry-crushing roller mill or of the Chilean type, the items will differ, of course, and may be added in the blank spaces. The cyanide forms will be more or less complicated, according to the particular appliances used, but most of the details of vats and solutions need not go to the office, but remain on file at the plant. Form No. 6 will cover many of the facts needed. The assay forms are not important; any statement of results will suffice.

The superintendent must now have all the facts necessary for his home reports made weekly and monthly. The weekly and monthly reports (form No. 7) may be of the same character, but need only

an account of the principal supplies used during the month, as in form No. 10.

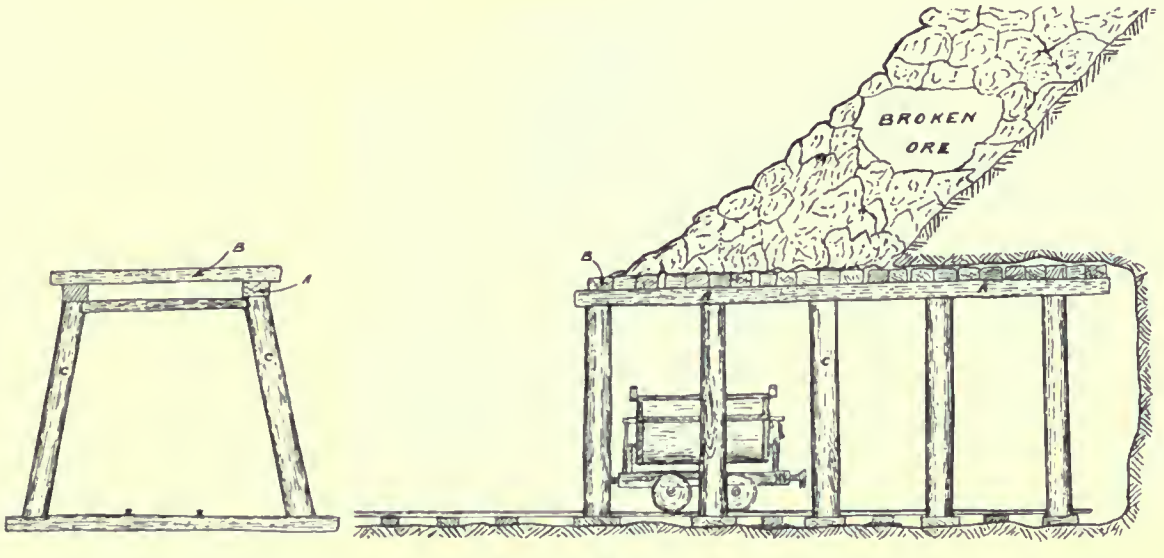
In case the office work is done at the mine, a complete copy of all transactions must go to the general office; this will include a bullion account, concentrate account, etc., which we need not consider at present.

Precipitation of Zinc From Solutions.—The United Alkali Co. has introduced a simple method of recovering zinc from liquors resulting from the wet copper process. It is a modification of the method in which the solutions are boiled with milk-of-lime. The theoretical amount of milk-of-lime is added at normal temperature, the solution being well agitated during the addition. The agitation is then stopped and the zinc precipitate as zinc hydrate is in a condition suitable for the production of zinc or its salts. For instance, if 1000 parts of liquor contain 34 parts of zinc, 30 parts of lime mixed in 500 parts of water are gradually added and the mixture agitated. As a rule, some iron is also precipitated in the ferrous state; if so, this is oxidized by exposure to the air or by suspension in water and admission of air.

METHOD OF MINING.

An economic method of quarrying rock or hard ore is shown in the accompanying diagram. Adits are driven into the hill to be quarried, the number depending on the tonnage expected and the size of the orebody. These are always kept about 50 ft. in advance of the broken ore, so as to allow space for a train of empty cars to be loaded conveniently. The adit is then heavily timbered as shown, with posts and sills.

In place of the usual transverse cap, a longitudinal stringer (A) of sawn timber, 6 by 8 in., is put on the top of the posts (C) and small stretchers are placed to keep the posts in position. Above the stringers are placed transverse pieces (B), for which railroad ties can be conveniently used, and these form the roof of the adit. Ore is then broken down on the timbers, and the cars are loaded by opening the transverse pieces with a bar. As the quarry advances, each adit will be at the bottom of a natural bunker, the sides of which are formed by the natural slope of the ore. The ore is blasted directly down



Method of Mining.

onto the top of the adit, the timbers being protected by a layer of broken ore. After a large blast the big boulders can be broken by bulldozing, and the ore need not be shoveled or handled until it falls by gravity into the cars. As the face advances and the broken ore recedes, the old timbers can be removed and again moved up to the face.

This method of mining is better than that of making a mill-hole, because there is no opening that can become blocked by large boulders, and the cost of preliminary work and equipment is reduced to a minimum. The adit should be made large and the timbering wide, so as to leave space enough for a man to load the cars, and get past them if necessary. The cost of quarrying and placing rock on cars should not exceed 10 to 15 cents per ton under favorable conditions and with a sufficient tonnage.

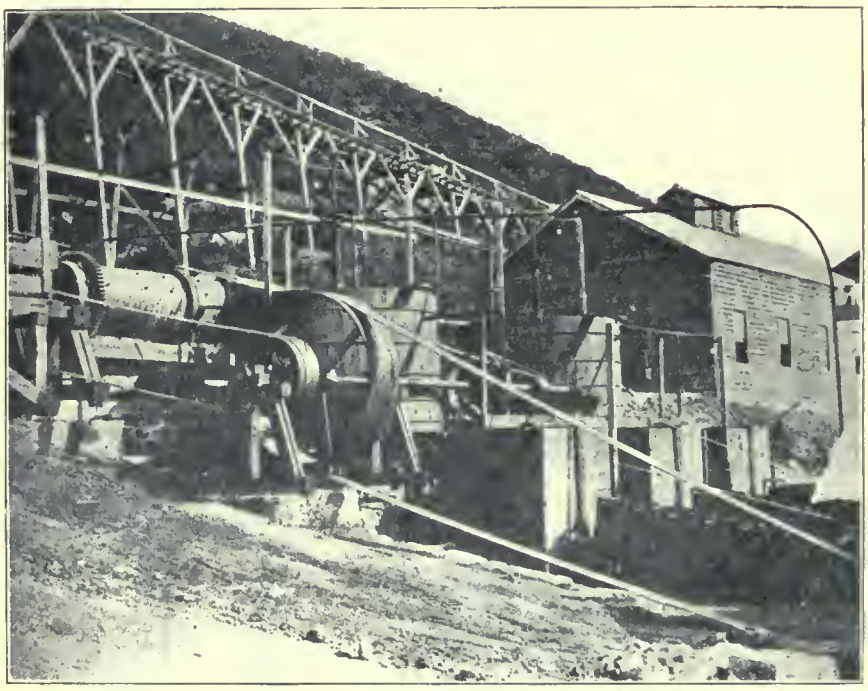
Old pick heads can often be used to make 'timber dogs.' These are always useful for framing timbers and rough carpentering.

TREATMENT OF A CONCENTRATE-SLIME.

Written for the Mining and Scientific Press
By A. E. Drucker.

A description of my vacuum-filter process as applied to heavy mineral or concentrate-slime may prove interesting, as it is quite different to other methods of filtering. I doubt whether a vacuum-filter of the Moore or Butters type will successfully treat this particular concentrate-slime, as it is not to be compared with an ordinary ore-slime. A combination of decantation and vacuum-filtering is the quickest and best method for such a product.

Very little information is obtainable from cyanide books or mining journals in regard to the cyanide treatment of concentrate. In a great many places the ore is concentrated before cyaniding and the concentrate shipped to the nearest smelter for reduction, the owners being content with high smelter charges and a (90%?) extraction. Most concentrates offer very little trouble to cyanide treatment providing the following points are observed:



Experimental Plant at Chittabalbie, Korea.

1. To be treated fresh and re-ground in a tube-mill with strong cyanide solution so that of all the product passing to an agitator at least 90% will pass a 200-mesh screen.

2. To be mechanically agitated and aerated for 15 to 20 hours within an agitator as described below.

3. The cyanide solution to test not less than 0.4% KCN when new and to test as high as 0.6% total cyanides after being in use for some time. For a short treatment of 24 hours do not attempt to cyanide with weak cyanide solutions testing only 0.15 to 0.2% and expect to get the best results. When treating a fresh clean pyrite 2 or 3 lb. lime per ton will generally be sufficient for all purposes.

4. Do not allow the strong cyanide solution to become so foul as to become inactive. This is one of the serious troubles in treating concentrate. A newly made solution free from reducing agents will give the best extraction and have the greatest dissolving power, but as it becomes older and takes up various foreign substances, which act as reducing agents, robbing the solution of its oxygen, the extraction gradually diminishes. The cheapest and most effective way of maintaining the extraction and of overcoming this reducing action is by a thorough aeration while agitating the pulp with cyanide solution. In treating concentrate it is not a bad plan to make up a new strong solution every six months.

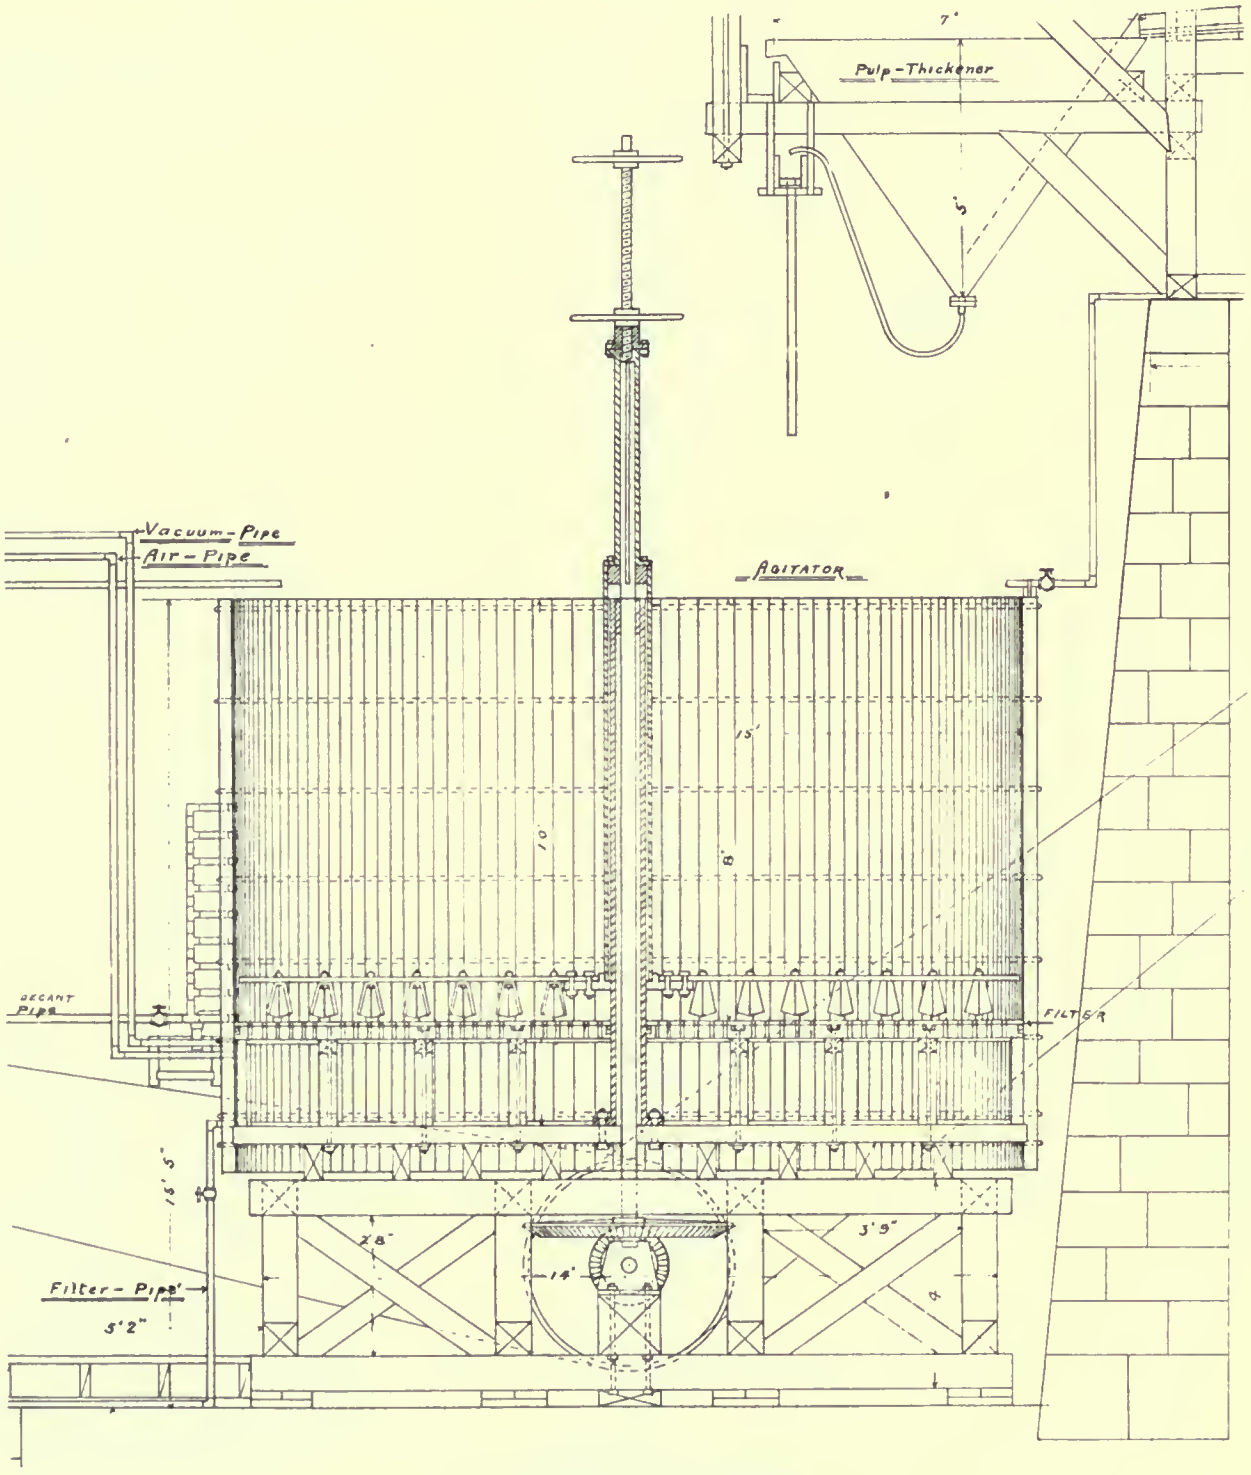
5. To rid the concentrate-slime of its gold-bearing solution the combined method of decantation and vacuum-filtering will be found to be the most efficient. A description is given below.

During the past two years I have had ample time to prove the success of this combined agitator and filter for treating a concentrate-slime at the experimental plant of the Oriental Con. Mining Co. in Korea. Before giving a description of the filter it may be well to describe in detail my method of cyanide treatment.

The concentrate when taken from the Frue vanners is practically clean; the material is conveyed to the tube-mill, mixed with a little lime, and fed to the automatic feeder with strong cyanide solution. Upon passing through the tube and being slimed in cyanide, the pulp flows to a spitzkasten, which yields two products—the underflow coarse and the overflow slime. The coarse is caught in settling-boxes and returned to the tube to be reground. Strong cyanide solution (used also in the tube) from the upper stock-vat is used for the upward sizing current in the spitzkasten. The clear overflow from the coarse settling-boxes passes to clarifying sand-filters and thence to zinc-precipitating boxes or directly to the strong sump. In order to maintain a constant pressure for the feed at the tube-mill and for sizing, a small centrifugal pump circulates the solution from the strong sump to the upper stock-vat, the overflow being conveyed back to the sump. The overflow slime from the spitzkasten (90% passes 200 mesh) flows direct to the agitator, in which a muller with plow-shoes is revolving at 15 rev. per min. The muller is lowered so that the points of the shoes are within ⅛ inch from the filter. Every charge receives from 18 to 20 hr. agitation and aeration. When aerating, air is forced beneath the filter and bubbles up throughout the charge. Everything seems to be actually boiling. Aeration and agitation are perfect at every point of the vat. After this operation is finished the agitation is stopped, the air turned off, the muller raised above the settled pulp,

and all allowed to settle for 30 minutes. With the aid of a little milk-of-lime, scattered over the surface of the solution, settling will take place within 15 or 20 minutes. Next comes the decanting of the strong cyanide-gold solution, which can be done to within 30% moisture remaining with the settled pulp. It is not necessary to wait until the solution becomes perfectly clear before decanting, since it is run into thin layer on top of the sand and is removed with a scoop every 3 or 4 days. The slime does not seem to penetrate the sand readily.

The pulp remaining within the agitator contains 30% moisture in rich gold solution and is next vacuum-filtered down to within 18% moisture. The agitator is set in motion and the muller gradually lowered through the pulp until the plows just begin to touch



Combined Agitator and Vacuum-Filter.

sand-clarifying vats and from there flows as clear as a crystal to the zinc-boxes. These clarifying-vats also serve as gold-solution storage-vats, so that the flow to the zinc-boxes can be regulated. Within each of these vats is a burlap filter four inches from the bottom and on top of each is one foot of clean coarse quartz sand. If the solution to be decanted is slightly cloudy all the slime therein will form a thin layer on top of the sand and is removed with a scoop every 3 or 4 days. The slime does not seem to penetrate the sand readily.

The pulp remaining within the agitator contains 30% moisture in rich gold solution and is next vacuum-filtered down to within 18% moisture. The agitator is set in motion and the muller gradually lowered through the pulp until the plows just begin to touch the filter. The shoes revolving next to the filter, prevent any slime-cake from forming, and when the suction is started beneath the filter, the gold-bearing solution is gradually sucked through into the compartment below. Before starting the vacuum the slime is quite thin when containing 30% moisture and agitates readily, there being no trouble in lowering the muller when plow-shaped shoes are at-

tached. I have never found any other form of shoe that will successfully work down on this heavy thick concentrate-slime, especially the last layer of slightly coarser material next to the filter which packs like cement. With a good strong suction beneath the filter the total time required to decant a solution and vacuum-filter the remaining slime down to 18% moisture is about three hours. The slime containing 18% moisture is very thick and sluggish toward the last, and it is possible to filter to 16 per cent.

After the removal of the strong solution (0.5%) there follows a 0.25% cyanide wash, assaying two to three cents per ton, which is thoroughly agitated for a few minutes, settled, decanted, and vacuum-filtered. Lastly, a weak 0.1% wash, assaying a trace in gold, is applied in the same way and upon the completion of this operation the extraction of the gold-bearing solution is practically complete. The charge is now ready to be run to waste. A little water is added, the discharge-hole opened, and the revolving of the muller will empty the agitator. A final water-wash is not necessary and consequently there are no waste solutions of any value. Both washes have their separate storage and clarifying-vats; they are run through their respective precipitation-boxes to corresponding sumps.

All details of construction of this filter will be found in the drawing. The muller has four arms at right angles to one another and to them are attached 26 cast-iron plow-shoes equally spaced. The shoes on opposite arms are arranged to work in between. The burlap filter is well braced 24 in. from the bottom and can neither bulge one way nor the other under pressure or vacuum. As a protection to the burlap one-inch boards bored with inch holes are placed on top and well spiked. The filter-cloth is between and the holes above should coincide with those below, as is shown in the drawing. The capacity of this 15-ft. agitator is 20 tons of clean pyrite-slime and it requires 5 hp. to run. The heavy pulp when once in motion at 15 rev. per min. takes very little power. The muller can be easily raised or lowered 2½ ft. During the past year I have obtained an actual extraction in bullion of 92% on a gold-bearing arseno-pyrite by the above method. This is a concentrate that gives a poor extraction (50 to 60%) by the ordinary 16-day percolation method.

An agitator of this type is particularly adapted to the treatment of a heavy sulphide slime. There is always a small amount of coarse concentrate that is bound to escape into an agitator from a spitzkasten, even though 90% of the total charge will pass a 200 screen. That part remaining on a 200-mesh, and even the coarser portion passing a 200-mesh screen, will give serious trouble to any other form of agitator, on account of being unable to work down on a cemented concentrate. There is only one form of shoe that will do it and that is the pointed plow. The charge can be settled for days and even then the muller will work itself downward through the last layer of cemented concentrate. That portion which settles compactly is nevertheless very fine and will practically all pass a 150-mesh screen.

With this arrangement a separate vacuum-filter plant is not needed. All the different operations of collecting, agitating, aerating, decanting, and vacuum-filtering are performed in the one vat, and therefore the method requires a plant of the smallest size.

ELECTRIC SIGNAL SYSTEM.

On the opposite page will be found the drawings illustrating the electric bell and flash-light signal system used in the Portland mine at Cripple Creek, Colorado. The scheme of wiring is shown in Fig. 1; the two wires leading to the dynamo are the same in each drawing, being separated for the sake of clearness. The grounding of the wires, as shown, is necessary only in case of a short circuit underground in the lighting system. The switchboard used in the mine is shown in Fig. 2; it was designed by D. C. McKeehan, the electrician to the Portland Gold Mining Co., and is made of rough lumber and ordinary porcelain insulators. The whole system exhibits three advantages:

1. By the addition of three wires, two separate systems of signaling are available.

2. The same current may be used for signaling as for lighting; batteries are unnecessary in mines that use electric lights or power underground.

3. The switchboard is of cheap construction, it is not affected by water unless entirely covered, and it is easily kept in order.

In regard to the electric plant at the Portland mine, there is a large number of motors in use, ranging from 3 to 300 hp. The current is three-phase 30-cycle alternating, as bought from the Pueblo & Suburban Co. on meter readings at the mine. One dynamo serves to operate the arc lights at surface. For this information we are indebted to Mr. F. M. Kurie, the superintendent of the mine.

The permanently frozen condition of the upper portion of the bed-rock of far northern lands is an advantage in the early stages of the development of quartz mines. On Seward Peninsula, Alaska, the ground of hillsides usually thaws in the summer to depths of 3 to 5 ft. This thawed layer is very soft and wet. The layer beneath it is thoroughly cemented by ice into a tough material exceedingly difficult to pick or break by blasting. It protects the rock beneath from the surface water, so that mine-openings are comparatively dry if the surface water is drained away from the entrance to them. The tough layer is usually only 5 to 10 ft. deep, and the material below it contains just enough ice to enable it to stand well without timbers, although it can be picked or blasted easily. Thus, broken ground or decomposed rock that in most countries would require careful timbering, on Seward Peninsula will stand for several years without any timber support. The depth to which the frozen ground extends has not been determined at many places. An adit at a tin prospect in the valley of Lost river had not reached the bottom of the frozen zone when its face was 112 ft. vertically beneath the surface.

Electric Signal System of the Portland Mine.

DEVIATION OF BORE-HOLES.

By Joseph Kitchin.

*Of the 235 bore-holes that have been sunk in the Witwatersrand area of South Africa to cut the Main Reef series of lodes, 45 have reached a depth of 3000 ft. or more. The surveying of about 40 of them has shown that the deviation from the vertical may be most serious, in ascertaining the position and width of the lode as shown by the core.

The results of the surveys of 22 bore-holes were selected for tabulation. The surveying engineers have usually calculated the extent of the horizontal displacement in a straight line and not according to the varying directions the bore-holes took, and the vertical depth below the surface at the point where the lode was struck, but in cases where this point is hundreds of feet lower than that reached by the surveying instruments, the determinations are estimates only. The average deviation from the vertical is given in the following table, arranged according to the depth reached by various surveys:

NUMBER OF BORE-HOLES.

Depth Ft.	1 to 8	9 to 16	1 to 16	17 to 22	1 to 22
500	4.7°	2.5°	3.6°	8.8°	5.0°
1,000	10.6°	9.2°	9.9°	15.6°	11.4°
1,500	20.2°	19.7°	19.9°	20.2°	20.0°
2,000	24.9°	27.8°	26.4°	25.4°	26.1°
2,500	27.3°	30.1°	28.7°	.....	.....
3,000	32.9°	34.4°	33.6°	.....	.....
3,500	42.5°	.....	.....	.....	.....
4,000	47.7°	.....	.....	.....	.....

The horizontal displacement caused by the curving of the rods has varied, in the case of the bores surveyed to a depth of 4000 ft., between the minimum of 700 ft. and a maximum of 2250 ft. All the other holes tabled lie within the limits of the extremes shown by the curves of these two bore-holes. The average horizontal displacements of the 22 holes are:

NUMBER OF BORE-HOLES.

Depth Ft.	1 to 8 Ft.	9 to 16 Ft.	1 to 16 Ft.	17 to 22 Ft.	1 to 22 Ft.
500	15	10	10	35	20
1,000	85	70	75	145	95
1,500	210	190	200	290	225
2,000	400	390	395	485	420
2,500	610	635	625	.....	.....
3,000	860	910	885	.....	.....
3,500	1,150	.....	.....	.....	.....
4,000	1,485	.....	.....	.....	.....

The total depth surveyed averages 3370 ft. for the 22 bores, the average horizontal displacement being 1165 ft., and the average vertical depth below the surface at the lowest surveyed points being 3015 ft. The highest recorded angle of deviation from the vertical is 66°, noted at a depth of 4400 ft. Some of the holes first penetrated dolomite, which lies flat and is non-conformable to the underlying Witwatersrand formation. In the case of bore-holes that throughout were in the latter formation, the horizontal displacement increases, approximately, as the square of the bore-hole length. This, however, refers to the average only; the rule applies much less strictly to single holes. The flatter the dip of the strata, the greater is the deviation.

The 21 bore-holes surveyed for the direction of deviation all went northerly, although the rock formation dips in all directions. All of them deviated within an arc of 111° (from N 37° W to N 74° E), and 20 of them within an arc of 87°. The average direction is N 11° E, and the average horizontal displacement at a depth of 3000 ft. is 900 ft. A significant fact is that all of these 21 bore-holes except one deviated against the strata, that is, in a direction toward the outcrop of the formation. (Bore-holes in Western Australia also are stated to have deviated against the stratification.) It is difficult to ascertain the strike of the formation in many instances, but taking the apparent strikes, the direction of deviation relatively to the strike of the rocks is confined within an arc of 177°. Excluding three holes, which are rather exceptions to the general rule, the arc is reduced to 68°, or 46° on the one side and 22° on the other of a straight line drawn at right angles to the strike in the direction of the outcrop. The average direction taken by the 21 bore-holes makes an angle of 85° with the strike. There is a predominant tendency for a bore-hole in going down to describe a right-handed (clock-wise) curve, so that a hole which at first deviates in a northwesterly or northerly direction usually moves around to the eastward.

Of the total distance penetrated by the 22 bore-holes, 75% was in quartzite and sandstone, 9% in shale and slate, 8% in dolomite, and 8% in diabase and other igneous rock. The influence different kinds of formation have in the matter of deviation can only be judged in a rough way on account of the long intervals between the surveyed points and the absence of sufficient information as to the character of the rocks intersected. Four bore-holes that passed through practically nothing but quartzite and sandstone from the surface to depths varying from 1895 to 3000 ft. show an average deviation at 500 ft. of 5°, at 1000 ft. of 10°, at 1500 ft. of 18°, and at 2000 ft. of 25°. In another hole there is a marked increase of deviation in quartzite, the angles being 7° at 1250 ft., 19.5° at 1500 ft., and 35° at 1800 ft., though below the last the increase is not so great. In one hole the angle increased in quartzite from 38.8° at 3000 ft. to 55.7° at 3500 ft. The average increase of deviation for this class of rock is about 6° for each 500 ft. In passing to slate or shale the deviation is usually continued at the same rate of curve as above it in the quartzite, but a few cases of marked change bring the average for all the holes that penetrated these kinds of rocks to about 8° for each 500 feet.

In the dolomite formation there is a distinct contrast to the foregoing results. Eight of the 22 bore-holes were started in dolomite or entered it at a moderate depth. Their average angle of deviation in dolomite is under 1° at 500 ft. and 2° at 1000 ft. (compared with averages of 7.7° and 15°, respectively, for bore-holes not started in dolomite), while there is a marked change directly the holes penetrate the underlying Witwatersrand formation. In the case of seven other holes (not included in the 22 tabulated in this paper) there was no appreciable deviation in the dolomite, which therefore stands almost alone in permitting bore-holes to pass through it in a practically vertical direction. Igneous rock, chiefly diabase, occurs in thicknesses of 30 ft. and

*Abstracted from *Bulletin* No. 34 of the Institution of Mining & Metallurgy, London.

over, in 16 of the bore-holes. This class of rock shows the same erratic results as slate and shale, but on the average the increase in deviation angle is 6° for each 500 ft. The igneous matter has not affected the curve of the bore-holes, with three apparent exceptions. Certain holes, after going down in a practically vertical direction through dolomite, continue to be practically vertical for hundreds of feet in the underlying diabase. A bore-hole started in diabase or other igneous rock would apparently follow the example of holes started in dolomite.

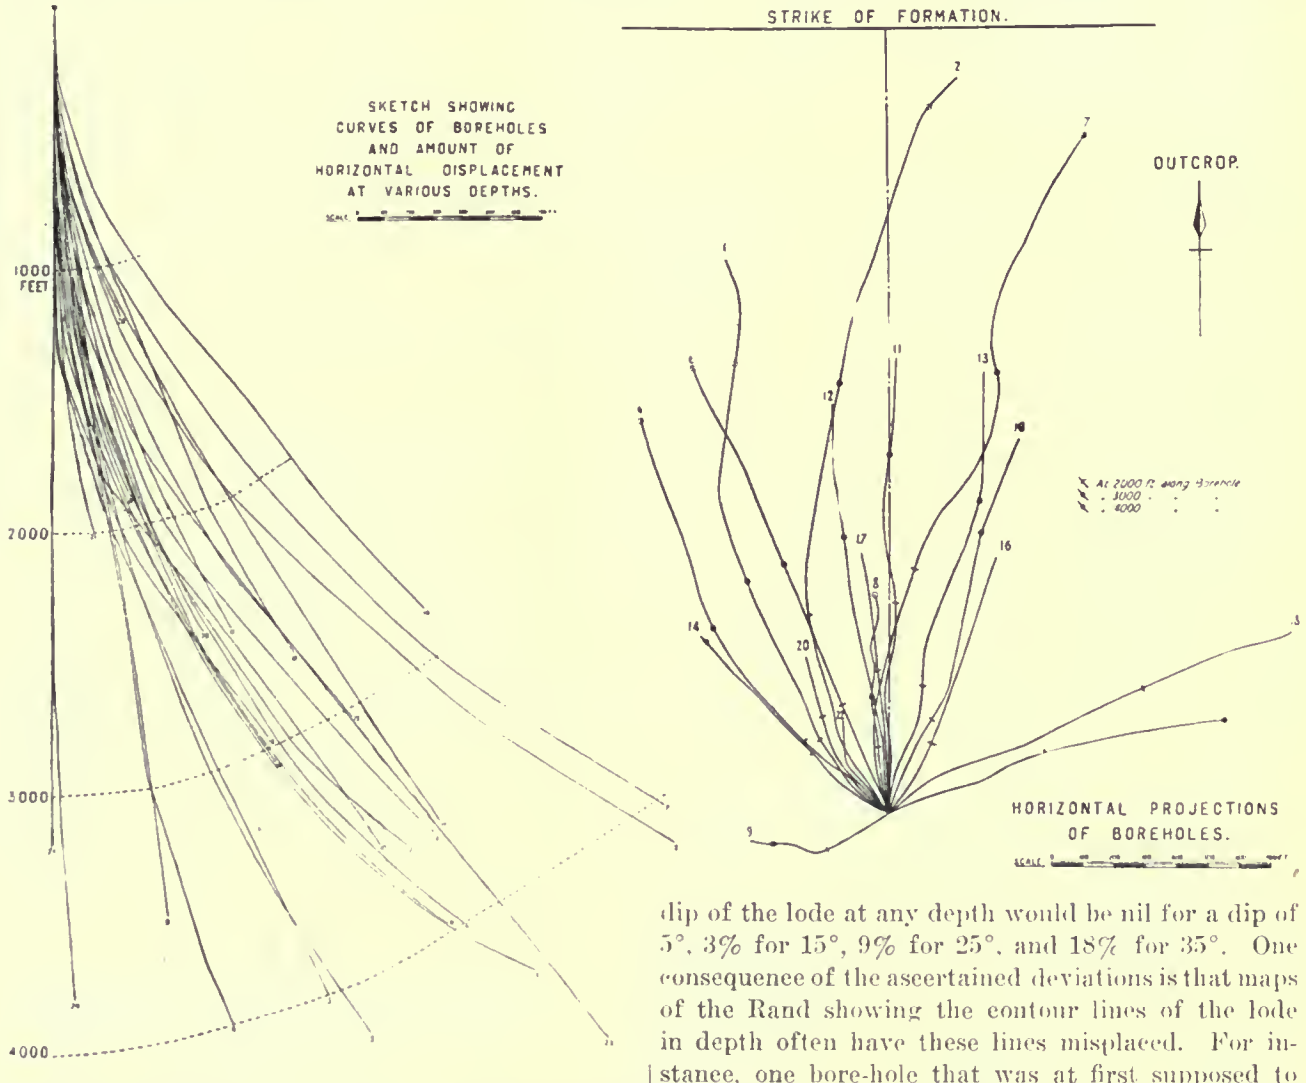
Sudden changes in the direction of deviation are noticeable in 5 bore-holes. In one there is a remarkable turn from N 96°E at 1000 ft. to N 19°E at 1250 ft.; this occurred at a point where the dolomite gave place to the Black Reef formation. In another there is a turn from N 16°W at 1400 ft. to N 14°E at 1650 ft., the only apparent cause being 7 ft. of igneous rock at 1467 ft. Other changes are accounted for by the bore-holes passing from quartzite to slate or diabase.

It is obvious that the data given by every bore-hole that intersects the Main Reef series requires to be corrected for the angle at which the hole cuts the lode-plane where it is not a right-angle. The deduction to be made from widths of ore shown by the core in order to make the necessary correction for both dip and deviation, if the bore-hole deviates directly against the strata, is indicated by the following table:

Depth of bore where it cuts the lode.	Deviation from the vertical assumed.	Dip of the Lode Formation from the horizontal.			
		5°	15°	25°	35°
Ft.		ft.	ft.	ft.	ft.
1,000	15°	1	Nil	1	6
2,000	27°	7	2	Nil	1
3,000	35°	13	6	1	Nil
4,000	50°	29	18	9	3

The correction, it will be seen, becomes especially important where the lode-depth in the bore-hole is 3000 or 4000 ft. and where the formation is nearly flat. If the bore were vertical the correction for the dip of the lode at any depth would be nil for a dip of 5°, 3% for 15°, 9% for 25°, and 18% for 35°. One consequence of the ascertained deviations is that maps of the Rand showing the contour lines of the lode in depth often have these lines misplaced. For instance, one bore-hole that was at first supposed to have struck the lode at a depth of 4419 ft. vertically under the bore-hole mouth, is now estimated to have struck it at an actual depth of 3288 ft. and vertically below a spot 2573 ft. away from the bore-hole mouth. Another consequence of the deviations is that over one-half of the bores tabled struck the lode in neighboring properties, thus largely vitiating the object of the boring.

With the aid of the results here massed one should be able to predict with a tolerable amount of probability how a bore-hole put down in the future will behave. If it were a 3000-ft. bore-hole sunk in strata of low dip, it would presumably show a horizontal displacement of between 600 and 1450 ft., with 1100 ft. as an average, and it would be likely to deviate directly against the strike of the formation, etc. With the aid of such data there



should be no reason why any future bore should cut the lode outside of the property in which it was begun.

It is perhaps easy to understand why bore-holes may deviate from the vertical, but it is difficult to ascertain why the deviations should result in the manner set forth above. The various suggestions hitherto put forward are mainly covered by the following:

1. That the deviation is due to the strata being inclined; this is rather strongly supported by the evidence, and may be said to be the general view.

2. In drilling through sedimentary strata one segment of the boring bit may be drilling in rock of different hardness from the other segment; if in softer rock the tendency will be for the bit to incline to that side, and a deflection once formed would appear to predispose to another. This is the view held by S. J. Truscott.

3. In passing into harder strata the boring bit has more work to do on the upper side of the strata, and the extra pressure consistently applied on this side gradually brings the hole to a direction at right angles to the plane of the formation. This is advocated by H. F. Marriott.

4. The first change of rock encountered in passing from softer into harder strata deflects the boring bit against the dip, and the deflection, once started, tends to increase in that direction, irrespective of further changes in the rock, as suggested by W. F. A. Thomae.

None of the above suggestions seems to account for the observed facts, though No. 4 perhaps is nearest to it. The paper was largely written in the hope of arousing a discussion among professional men.

In the discussion that followed,* J. N. Justice called attention to the fact that the longer and stronger the core-barrel, the less the tendency to deflect. He suggests that the excessive deviation may be due to needless heavy pressure upon the rods, and cites instances. W. F. A. Thomae says that while Mr. Kitchin's conclusions as to the probable behavior of future bore-holes in the Rand formations seem fairly obvious, it is doubtful whether in less regular formations the same uniformity in the behavior of drill-holes could be relied upon. He also conceives that if the drill meets a hard bar at a very acute angle there would be a tendency to force the bit in the direction of the dip, opposing the tendency to deflect against the dip as explained by Mr. Marriott.

In introducing† his paper, Mr. Kitchin cited Mr. Zboril as stating that 80 to 90% of the boring on the Rand has been effected with B rods, which are 1¾ in. diam., yielding a core of 1⅜ in. The rods and core-barrel are in 10-ft. lengths. The carbons at first protrude beyond the crown $^1/_{16}$ in., this is reduced to $^1/_{32}$ in., and then to $^1/_{64}$ in. Thus, the diameter of the bore-hole is 2⅛ in. at the top, $2^1/_{16}$ in. in the middle, and $2^1/_{32}$ in. in the lower portion. Mr. Zboril in his paper proposes, as a possible means of reducing deflections, (1) to take great care in starting the bore-hole vertically; (2) to strengthen the core-barrel, especially the shell portion; (3) to use smaller bits in the upper portion of the bore-hole to reduce the play between the core-barrel and the walls; (4) to reduce the pressure brought to bear on the lowest portion of the boring bit; and (5) to watch the rods closely for any vibrations, and stop them by stopping the drill.

Hugh F. Marriott, after explaining the method of sinking a bore-hole, said that in order to save the crown, in going through dolomite containing chert, the drill was run very light and there was no tendency to force the drill and induce a curve one way or the other: this was one of the chief reasons why in dolomite the drills kept straight. He also expressed the fear that Mr. Kitchin had attempted the impossible in formulating a set of rules to predict the behavoir of a bore-hole prior to its being sunk. As to the bore-holes all going in a northerly direction, it was merely the result of the work being carried out in southwardly dipping strata.

C. Baring Horwood corrected the statement that a 10-ft. core-barrel was usually employed; it was customary in the Transvaal to use a 20-ft. and sometimes even a 40-ft. core-barrel.

W. H. Trewartha-James attributed the initial deviation to three causes: Over-setting the diamonds; too much play between the core-barrel and the hole, or between the drill-rods and the hole; and pressure on the boring rods. When the deviation first began to make itself felt the drill sought the line of least resistance, and if this first tendency was met by a plane of harder material acting in the opposite direction, he thought the drill would be deflected back. Further, he did not think that the average of the deviations tabulated by Mr. Kitchin could be regarded as applicable in the practical work of laying out bore-holes. He suggested that holes should be surveyed while boring is in progress, and those which show abnormal deflection should be abandoned; one way to attain a more accurate hole is to increase the size of the core and the strength of the core-barrel.

Mungo Park advised the use of a long barrel. He thought it possible that magnetic attraction of the drill-rod may have been the cause of the northward deviation of the bore-holes, but it was subsequently brought out in the discussion that the lower end of the rod would probably have S-seeking polarity.

L. H. Cooke announced two principles: (1) Inclined holes tended to flatten and eventually to rise; (2) where very soft rock was encountered at an angle the rods tended to drift along the soft beds. To this Mr. Park added that a hole whose deviation is proportional to the square of its depth forms a 'conic parabola,' a curve of constant acceleration or the curve of a constant force.

Finally, Mr. Kitchin closed his highly interesting discussion, only fragments of which are given here, by the advice to keep close to the boring point with the survey; when a hole shows a tendency to depart from the vertical, run the drill more lightly; and when the deviation becomes more serious, re-start the hole from a higher point.

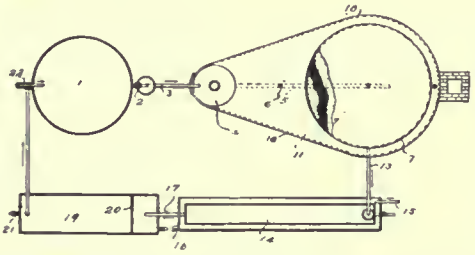
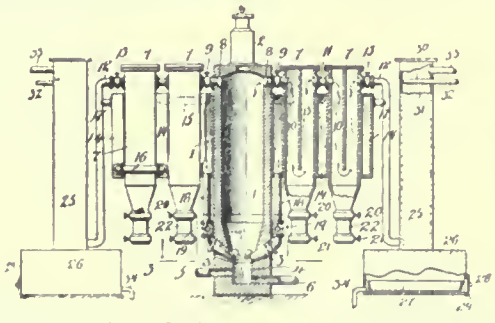
Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE-CONCENTRATOR.—No. 881,013; Ray H. Manley, San Francisco, California.



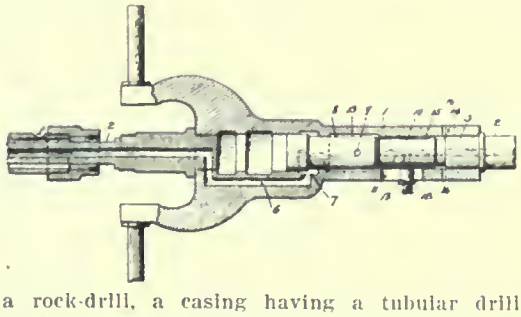
An ore-separator, comprising standards connected together at their upper ends, a cross-shaft journaled in the standards, having a cam and bevel wheel fixed thereto, a vertical shaft journaled in the connecting portion of said standards, having a head, a bevel wheel in engagement with the first-named wheel, slidably splined to the vertical shaft, a spring interposed between the last-named wheel and the head of the shaft, normally facing said head in contact with said cam, a bowl fixed to the upper end of said shaft, and an apron surrounding the upper edge of said bowl and fixed to said standards.

PROCESS OF REDUCING ARSENICAL ORES.—No. 879,932; Gustaf M. Westman, New York, New York.



The process of producing metallic arsenic consisting in subjecting arsenical ores to the action of heated reductive gases containing carbon monoxide, and then condensing the arsenical vapors passing from said ores.

ROCK-DRILL.—No. 881,059; Henry J. Cook, Ottumwa, Iowa.

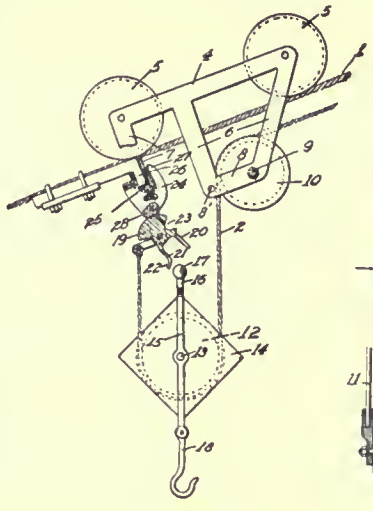


In a rock-drill, a casing having a tubular drill-stem mounted at one end, an air-propelled hammer, a striking-head mounted between the hammer and the drill-stem having a hole therein that registers with the hole in the drill-stem, and a hose connection secured to said striking-head and communicating with the hole therein, substantially as shown and described.

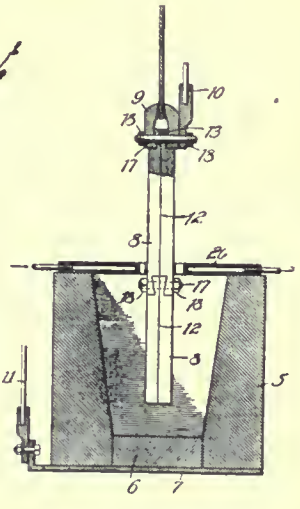
BLASTING-FUSE IGNITER.—No. 881,714. Benjamin F. Pearson, Canyonville, Oregon.

A fuse protector and igniter comprising a metal cap having a reduced or contracted outer end and adapted to be applied to the outer end of the fuse and means in the outer end of said cap whereby the fuse may be quickly ignited, substantially as described.

HOISTING AND CONVEYING APPARATUS.—No. 879,744; John W. Cooper, Seattle, Washington.



No. 879,744



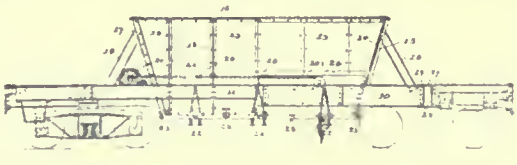
No. 881,520

In combination with a track, a carriage mounted thereon and a hoisting rope supported on said carriage, a rotatable lock element on said carriage, said element being formed with a depression, a movable catch disposed to engage in said depression when said element is rotated, a means fixed on said element and operated by said rope to rotate said element, and a projection on said rotatable element to prevent lowering of the load, said projection having a downwardly and outwardly projecting guard.

SECTIONAL ELECTRODE FOR ELECTRIC FURNACES.—No. 881,520. Charles E. Wilson, Ferris, West Virginia.

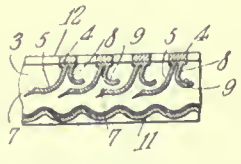
A pencil-electrode section for electric furnaces, formed of separate longitudinally extending members, fitting closely together at adjacent sides and provided at opposite ends with means for clamping the members together, and for securing the sections endwise to other sections.

METAL ORE-CAR.—No. 874,576; Ethan I. Dodds, Pullman, Illinois.



In a car of the class described, the combination with the side-sills, of a series of side-stakes secured to the inner faces of said side-sills, and a load-holding receptacle having its side-walls secured to said side-stakes, substantially as described.

ORE-SEPARATOR.—No. 881,526. James R. Yount, Nyssa, Oregon.



The combination with a sluice; of a plurality of riffles suspended therein, each riffle comprising a deflecting member and a pocket member, the deflecting member of each riffle being disposed below the pocket member of the adjoining riffle.

PROCESS OF TREATING ORES.—No. 881,101; Stanley C. C. Currie, Los Angeles, California.

The herein described process or method of extracting bismuth from ores, which consists in passing a hot caustic alkali solution through the ore containing bismuth and maintaining the heat of the ore in the solution during such passage, and finally withdrawing the solution.

CATALOGUES RECEIVED.

THE WESTERN ELECTRIC CO. have issued Bulletin No. 5910, illustrating power equipment for cement mills.

THE T. R. ALSING ENGINEERING CO. have published a booklet descriptive of the evolution of the tube-mill, and explaining their improved driving system.

VULCAN SELF-CONTAINED STEAM HOISTS for mine, quarry, or construction work are described in a leaflet forwarded by the Vulcan Iron Works, Wilkes-Barre, Pennsylvania.

THE DENVER FIRE CLAY CO. has sent Bulletin No. 19, describing the Case laboratory crusher, which is a strong and fast machine with a simple and efficient cleaning device.

THE STROMBERG-CARLSON TELEPHONE MFG. CO. has forwarded a leaflet explaining the uses of the Mine-a-phone and the economy and safeguard of a telephone installation in a mine.

THE WESTERN ELECTRIC CO. has issued its 1908-1909 catalogue. This fully describes all lines of electric supplies made by the company. The local house is at 642 Folsom St., San Francisco.

THE MORAVIA CONSTRUCTION CO., of Chicago, has issued a booklet descriptive of its standard steel suitable for manufacturing buildings, coal and ore handling apparatus, and all kinds of bridge-work.

THE BROWN HOISTING MACHINERY CO., of Cleveland, Ohio, has published a catalogue describing its grab-bucket loading cranes for handling coal and ore, and illustrating the various uses to which these machines are adapted.

THE W. S. TYLER CO., of Cleveland, Ohio, has forwarded its price list of Catalogue No. 24. This contains a number of useful tables referring to wire cloth and screen, together with a price list of trommels and all varieties of double-crimped screens.

THE WOOD DRILL WORKS has prepared for distribution its latest circular, F-4-8, explaining the simplicity and efficiency of its machines, as shown by their work on the great Zuni dam, New Mexico, which has just been completed by the Department of the Interior.

BOOKS RECEIVED.

'The Copper Handbook,' Vol. VII, has just been issued by the author, Horace J. Stevens, of Houghton, Mich. The book has 1228 pages, octavo, brevier type, being larger than before. This new edition of 'The Copper Handbook' contains 25 chapters, an increase of nine, treating of copper under the headings of History, Geology, Chemistry, Mineralogy, Mining, Milling, Concentrating, Hydrometallurgy, Pyrometallurgy, Electrometallurgy, Alloys, Brands, Grades, Uses, Substitutes, Terminology, Geography, Copper Deposits, Copper Mines, and Statistics. The treatment given the subject in 1228 pages is encyclopædic in scope, but the logical and orderly arrangement of the great mass of facts presented, coupled with a table of contents, full index and alphabetical arrangement of districts, countries, mines, minerals, and glossary, render it possible to ascertain any given fact with almost as much ease as a word is found in a dictionary. This is a point of much value to readers that has been overlooked in many otherwise excellent works of reference. 'The Copper Handbook' is not intended to replace other works for the use of technical men, but it does supplement all other technical books on copper, while for the average reader its hundreds of pages devoted to the scientific and technical features of the subject will be found to cover every point of interest. The language is plain throughout, and the layman, whether miner or investor, will find the clear and easily understandable exposition of scientific facts a great aid, as the highly technical language used in many of the best scientific works is a serious stumbling-block in the path of the man not technically trained, who is forced to read such books with a dictionary at his elbow. In whatever light 'The Copper Handbook' is viewed, whether in describing the thousands of different copper mines, in all parts of the world, in the plain descriptions of intricate processes of mining, milling, smelting, and refining, or in the forty pages of statistics covering the copper industry of the globe in its various commercial and financial aspects, the book must stand as a monument of patience and labor, it being the unaided work of a single man. The price of the book is $5, and it is for sale by the MINING AND SCIENTIFIC PRESS.

'A Text-Book of Mining Geology,' by James Park. 220 pp. Price $2.25. Published by Charles Griffin & Co., London. For sale by the MINING AND SCIENTIFIC PRESS. This handy volume is the work of the professor of mining geology in the School of Mines of the University of Otago, New Zealand. It is carefully written and adequately illustrated, with drawings and plates that are well printed. The author is a man of experience, both as an observer and a teacher, so that he knows what facts are pertinent to the subject. He is a scholar, as is suggested by the thoroughness and completeness of his references to other authors. The style is good, that is, it is suited to the purpose; it is clear and concise. We commend this volume heartily to mining engineers and economic geologists.

'Gas Power,' by F. E. Junge. Hill Publishing Co. 640 pp. Price $5. This book gives a complete scientific account of the practical achievements which have been realized in the design, construction, and application of gas-engines, producers, and power plants, up to the largest size. The book gives detailed working drawings, with descriptions for the design of all the principal parts of large gas-power machinery, and a detailed survey of the successful methods of utilizing blast-furnace gas and other cheap fuels. The latest practice of German engineers is described fully, and this is valuable because the economic conditions in Germany have developed this branch of industry to an unrivaled position.

We have received Bulletin 331 from the U. S. Geological Survey, on 'Portland Cement Mortars and Their Constituent Materials,' by R. L. Humphrey and W. Jordan.

COMMERCIAL PARAGRAPHS.

G. B. SHIPLEY, engineer of the ALLIS-CHALMERS CO.'s mining machinery department, is at Goldfield, Nev., where he, in conjunction with J. B. Fleming, for the Goldfield Con. Mines Co., is preparing the plans for the 100-stamp mill to be erected by the latter company at Goldfield, Nevada.

THE HUG WATER WHEEL CO., 1516 Blake St., Denver, Colo., has recently installed a 300-hp. Hug water-wheel, direct connected, for the Salida Light, Power & Utility Co., at Salida, Colo., and has recently received an order from the Muldoon Mining Co., Muldoon, Idaho, for a 225-hp. unit, which is being prepared for shipment.

THE A. & E. CONCENTRATOR CO., 1618 Glenarm St., Denver, Colo., has recently installed two A. & E. Slime Concentrators at the Pollock M. & M. Co.'s 20-stamp mill, Salina, Boulder county, Colo., where they are making a good saving below the plates and other concentrating tables. This machine has been thoroughly tested before it was placed on the market.

THE WEBER STEEL CONCRETE CHIMNEY CO., of Chicago, announces that, owing to increasing its field of activity in taking on other kinds of plain and reinforced concrete construction work, in addition to chimneys, it has been decided to change the name of the company, so that hereafter it will be known as THE WEBER COMPANY, general offices as before at 929-934 Marquette Bdg., Chicago.

L. Vogelstein & Co., New York, give figures of German consumption of foreign copper for the month of January, 1908:

	Tons.
Imports of copper	14,614
Exports " "	454
Consumption of copper	14,160

as compared with consumption during January, 1907, of 8332 tons.

Editorial.

AN AMERICAN Iron and Steel Institute has been organized at New York. It is stated that the object of the organization is "to afford a means of communication between members of the iron and steel trades upon matters bearing upon their business interests. The directors include Elbert H. Gary, W. E. Corey, and Charles M. Schwab. Apparently the officials of the United States Steel Corporation are responsible for this new institute.

WE ARE GLAD to be able to announce that Mr. Courtenay De Kalb has become associate editor. Mr. De Kalb scarcely needs an introduction to our readers, and his contributions will have indicated his fitness for such work. For 15 years he has been in active professional practice, and for 7 years he served as professor of mining and metallurgy in the schools of mines of Missouri and Queens University, Canada. Mr. De Kalb will cease practice as an engineer and will devote himself exclusively to his new duties. A Virginian by birth, a New Yorker by education, and a Western American by choice, he will be warmly welcomed by the technical men resident in San Francisco and by the readers of this journal everywhere.

TWENTY-FIVE YEARS ago a million was a fabulous price for a mine. When William Letts Oliver bought the Plumas-Eureka mine, in California, for $1,000,000, in behalf of his English clients, the transaction was considered without precedent. Nowadays men talk of $50,000,000 companies and $100,000,000 consolidations as if they were boxes of cigars. An industrial concern that cost $36,000 is sold for $750,000 and the promoters make over 2000% by allowing only 4% interest on the capital and making estimates based on boom prices for their commodity. No wonder men get drunk with money-making; it is a gambling debauch, and the panic has not ended it. There are signs of a renewal of this orgie of speculation. It always ends in fortunes for the few and disaster to the many.

GEOLOGY is the friend of mining, and the geologist is the comrade of the engineer. Therefore any dissertation on the science of geology, when delivered by such an authority as Mr. James F. Kemp, is sure to be read with relish by the miner. The lecture of the Professor of Geology in Columbia University has previously appeared in the *School of Mines Quarterly*, from which we reproduce it by permission. The reprints issued by the University bear the crest of the English crown. This will remind the reader that Columbia was founded as King's College: over the gateway there used to swing a big iron crown, which now stands above the centre of

the hearth in the trustees room of the new Columbia University. The leading student club is called the King's Crown and thus serves to recall colonial times.

A GOOD EXAMPLE of newspaper science is afforded by the following description of the manufacture of portland cement, as given by a San Francisco daily paper to a correspondent at Ukiah. The seeker after knowledge is informed concerning portland cement that "it is made by mixing chalk and clay, calcining the mixture until it begins to vitrify, then grinding the clinker to a fine powder. In the process, workers employ rather different calcareous argillaceous components in proportions which experience has proved most suitable for the purpose. In amalgamating the two raw materials, in the preliminary step, the wet or dry process may be used." The technical absurdities are bad, but no worse than the misinformation given by the same paper on any subject. Just think of the people whose reading is limited to the daily press! No wonder they are easily impressed by charlatans and pseudo-reformers of every kind.

WITH REFERENCE TO the mining law, it is interesting to note that an attempt was made to adjust the rights of two friendly neighbors at El Oro, in Mexico, by an agreement based on a modified law of the apex. But it did not work. The El Oro and the Somera mines are contiguous and under the same control; in fact, the latter is a subsidiary company formed by a sale of a part of the El Oro territory. Under the agreement of sale to the Somera company, the El Oro company protected its right to follow the main lode, or San Rafael vein, in depth, notwithstanding its dip into Somera ground. It was also stipulated that any veins within the Somera property that had their apex in El Oro ground were to belong to the El Oro company. Similarly, any veins uniting with the San Rafael vein in depth, or any branches therefrom, should be deemed to be the property of the parent company. Thus the Somera was entitled only to such veins within its territory as apexed within its own boundaries. As the Chairman said: "In theory this was very simple and very nice, but the scheme broke down in practice." Several veins were cut, for there exists a whole system of embranchments, but until it was proved where a given vein apexed going up or whether it joined the San Rafael going down, it was not possible to make an accounting of the ore. The dilemma was easily overcome, and pleasantly, by an amalgamation of the two companies, so that the mining law was not illuminated, and the prospects of the mining companies were not darkened, by a lengthy litigation.

THE WELFARE of laborers in reduction works, a subject treated interestingly by Mr. L. S. Austin in another part of this issue, offers a fruitful theme for discussion. It should call forth the opinions of those who have had experience in practical endeavors for the amelioration of the conditions surrounding laboring men in their daily round of work, and especially should it draw the criticism of those chiefly interested, namely, the laboring men themselves. Care for the employee's welfare should be a purely utilitarian matter. The labor unions in a large sense represent, among other things, a protest against the benevolence of so-called reforms, which have proved ineffective because savoring too strongly of charity. Whatever lessens the self-respect of men fails to accomplish good, and the wage-earner has ever resisted becoming even in appearance an eleemosynary. Thus many well-meant efforts for bettering his condition at mining and metallurgical plants have failed, because the workman resented being coddled. Even legislative requirements touching matters of hygiene and protection against accident, which have been extensively developed in the European countries, have not satisfied the laboring people. An experienced mine manager, who had instituted numerous improvements in sanitation, and in the housing and feeding of his workmen, after witnessing the practical abandonment of the baths, the disuse of the reading rooms, the defiance of the sanitary regulations, and the denunciation of the company's boarding-house maintained on a simple cost-earning basis in order to provide clean nourishing food at small expense, gave it all up and remarked, "the working people will not let one be kind to them." It is not to be assumed that such is the truth, but rather that some defect lay in the method, and it seems to inhere in nearly all systems which have been tried. It would be interesting to learn from those most nearly concerned what it is, according to their view, that attracts or repels in the provision made by corporations for the personal comfort and convenience of employees.

Technical and Other Journals.

EFFORTS have been made to distinguish between trade, technical, and scientific journals. The last Director of the United States Geological Survey undertook to label some papers as 'scientific' and others as 'trade.' The differentiation was well meant, but unsuccessful. After all, if made sincerely, the classification is not difficult; no more difficult than the division of athletes into 'amateur' and 'professional.' The first jumps, runs, or plays ball for the love of it and accepts no payment, the latter does the same things for money or to earn an honest livelihood. A 'scientific' periodical is conducted in the interest of science and with no thought of gain; such are the quarterly journals of some scientific societies, the records of the Carnegie Institution, and the bulletins of the Survey; the managers of them accept no advertising, the cost of printing comes from the treasury of an organization of scientific men, from the Government, from Heaven it may be, or Carnegie, but in any event it does *not* come from the selling of publicity in the form of advertising space. There are some true scientific periodicals, but there are not many of them; as soon as they accept advertisements they become 'trade' papers, for advertising is as surely the mark of a trade paper as the acceptance of money is that of a professional athlete. In this sense our friends *Eco-*

nomic Geology and the *Bulletin* of the American Institute of Mining Engineers are 'trade' periodicals; but there is nothing necessarily debasing in that, and as a matter of fact certain forms of journalism, like certain sports, tend to become commercial simply because it is impracticable to conduct them without an income derived from the work. The 'technical' paper combines the characteristics of both the 'scientific' and the 'trade' publication. 'Technical' papers are those that deal with the sciences employed in manufacture and industry, their reading pages being devoted to the application of scientific methods for commercial purposes, as geology is applied to mining, chemistry to manufacturing, electricity to power and illumination, mechanics to engineering. They are a combination of the 'scientific' and the 'trade' journal, for their reading pages cannot be bought, while their advertising pages are for sale, and it is the integrity of the one that gives value to the other.

Let us narrow the discussion to a consideration of papers devoted to mining and metallurgy, for that happens to be the phase of the subject with which we are familiar, and it is well to discuss only the matters concerning which we know something at first hand. The ideal technical journal devoted to mining and metallurgy will give accurate and interesting information on these subjects without prejudice of any kind, it will not favor any machinery or other manufactured product, nor permit its reading pages to be used for the exploitation of anyone's wares, the proper place for such purposes being on the advertising pages. Ideally, the right hand should not know what the left hand doeth, the editor should not know who is advertising or likely to advertise in his paper. This may seem to many to be but an iridescent dream, and some of our experienced publisher-friends in New York will smile at such impracticable notions, for to them the reading matter is a lure for advertising, and the editor is a necessary evil, required to present a certain modicum of stuff on which to hang a profitable mass of advertising. Ideals are unattainable; when attained they cease to be ideals. We confess that the ideal technical paper does not exist nor is it likely to appear for a little while, nevertheless, a much nearer approach to it is possible if we give practical expression to our hopes, for the ideal is the terminus of hope. We can imagine a paper the reading matter of which was wholly independent of the advertiser—not mentally detached, but commercially separate. The purpose of the editor would be to give true and interesting information—interesting because true and yet made additionally attractive by the method of presentation—concerning mining and metallurgical matters, together with such comment as might emphasize their important features and stimulate the discussion of them to useful purposes; then, having an eye to a publishing business to be made profitable in an honorable way, he would select the subject-matter likely to arouse the attention of those to whom is sold the machinery advertised in the other portion of the journal. It happens that the engineers and men of business that select the machinery for mines and smelters are among the best educated and most intelligent in the modern world, so that if he, as editor, aims to interest such men, he is also likely to publish a paper useful and attractive to everyone engaged in the mining and metallurgical industries. Anything that makes the reading pages interesting to the reader, makes the advertising pages valuable to the advertiser.

A Treasure Island.

WE ARE IN RECEIPT of a letter sent to a correspondent offering him the chance to participate in great wealth suddenly. Some of our readers may be desirous of the opportunity to invest their savings in a permanent manner in a locality where "the warm Japanese current tempers the atmosphere"; for it is an island off the coast of Alaska. On this island there is a gold mine with a 5-stamp mill and in the bay close-by there are lots of ducks and geese. An engineer estimates that there is over $500,000.00 (note the unnecessary ciphers; men of imagination like to use them; they suggest more of the same kind of thing) worth of ore, which will yield $240,000.00 (again those expansive ciphers) net per annum; at least it will yield that much if it is there or, better still, if you take it from a bank and put it there. Next, "there is one ledge of gold ore near the lake that is over 100 feet wide that assays from $10 to $85 per ton in free gold." That is so obviously truthful; have we not seen many veins 100 feet wide, assaying ounces per ton, that just bobbed above the surface awaiting the pick of the deserving prospector! Moreover, a few miles inland there is a large lake and there you will find "a marvelously rich dredging proposition, the gold having been accumulating for ages in the bottom of the lake as it is washed down from the immense ledges of gold known to exist on the hills beyond." Naturally, that is the usual thing in the way of concentration of gold and that is why so many lakes are being dredged successfully today at Kalamazoo and Timbuctoo. But could not the lake have been enriched from the ledges if they had **not** been "known to exist in the hills beyond"? This is the one statement that needs explanation, otherwise the story is well founded and it ought to go far (as an air-ship) in stimulating the interest of cautious financiers. The engineer estimates that "at least one million dollars in gold net per year" can be taken out of this lake "for the next 100 years." The philanthropist connected with this enterprise is named Beer, which reminds us of the brewery that was auctioned by the great Dr. Johnson; on that historic occasion he pointed out that no common brewery was being offered for sale but "a potentiality of wealth beyond the fondest dreams of avarice." So this treasure island is no ordinary mining undertaking, it is a mineral empire surrounded by water, possessed of riches to which the glories of the Arabian nights were but the glitter of the pawnshop and to which the sheen of all the gold of Solomon was as the glimmer of the glow-worms in the pallor of the dawn. Selah.

Personal.

ROBERT R. HEDLEY is at Montreal.

D. MAIN is at Sydney, New South Wales.

T. A. RICKARD has gone on a short visit to Goldfield, Nevada.

D'ARCY WEATHERBE is in London. He intends to visit Cornwall.

CHARLES D. KEADING has returned to Goldfield from Stimler, Nevada.

ROBERT SCHORR will leave New York on the *Kaiser Wilhelm* next week.

M. L. REQUA was at Carson City for a few days and is now at Goldfield.

HORACE G. NICHOLS has returned from London to Nelson, British Columbia.

CHARLES BUTTERS left this week for Virginia City, to be gone several days.

H. G. PALSGROVE is in charge of mines at Cuatro Cienegas, in Coahuila, Mexico.

JOHN F. NEWSOM, of Stanford University, was in San Francisco this week.

J. H. CORDNER-JAMES has become a director of the Copiapo Copper Mining Co., Chile.

JAS. E. BRIENAGE is general superintendent of the Flagstaff mine, at Alta, Utah.

C. W. MERRILL is at Blair, Nevada, where his filter-press system is being installed.

GRANT D. MILLER is cyanide superintendent at Greenville, in Plumas county, California.

WILLIAM DAVEY is superintendent of mines for the A. S. & R. Co. at Velardeña, in Mexico.

A. L. GOLDIE is assistant to the superintendent of the Combination mill, at Goldfield, Nevada.

W. M. BREWER passed through San Francisco on his return from Goldfield to Victoria, B. C.

A. G. MCCRAE has been appointed assistant engineer at the Spassky copper mine, in Siberia.

H. M. THOMPSON is superintendent for the Midas Gold Mining Co., in Shasta county, California.

NORRIS ENGLISH has returned to San Francisco from the examination of mines in western Oregon.

A. M. YONGE has left Amador City to become superintendent of the Aguacate mines in Costa Rica.

S. F. HUNT is manager for the Nevada Lead Co., which is developing a mine at Hamilton, Nevada.

L. S. PIERCE, manufacturer of the Pierce amalgamator, has returned to Denver from a trip to Georgia.

W. MORTON WEBB is leaving Leadville to become manager of the May Consolidated mines in the Transvaal.

W. H. TREWARTHA-JAMES has been appointed general manager for the Tyee Copper Co. He is expected at Victoria.

CARNEY HARTLEY, who has had charge of construction work for the Colorado Dredging Co. at Breckenridge, has returned to Denver.

S. E. BRETHERTON has returned to Redding from a short visit to Boston. He is about to go to Nevada to examine mines near Goldfield.

F. L. BOSQUI is designing the cyanide plant for the 100-stamp mill of the Goldfield Con. Mines Co., and will remain at Goldfield for several weeks.

W. R. THOMAS, late of Tywarnhaile, has been appointed manager of the Botallack mine in succession to WILLIAM THOMAS, who is now resident at Camborne, acting as consulting engineer to the Allen & Meyerstein group.

ALVIN B. CARPENTER will reside at Los Angeles. The firm of Carpenter & Brennan has become Carpenter, Brennan, & Ryan, by the inclusion of EDWARD P. RYAN, recently assistant general manager for the Guanajuato Development Company.

General Mining News.

ALASKA.

(Special Correspondence).—The prospects for a big clean-up from winter work are good. The discoveries of the last few weeks of phenomenally rich pay in a number of places over the tundra give assurance of a large yield of gold-bearing gravel from Little creek, Glacier creek, McDonald creek, and Otter creek. Irene creek and Cunningham creek have come into prominence this winter, and should yield nearly half a million. The submarine beach is proving to be a uniform deposit of fair grade and great extent. The promise of a lively summer is evidenced by the big dumps of pay gravel dotting the lowlands at the back of Nome. As spring advances work is redoubled with increased energy, many operators having already begun the working of two shifts.

The census report published last year shows that in 63 factories of Alaska 2263 wage-earners received $1,365,709, or an average of over $647 each, in a period covering about six months actual labor. These factories (nearly all in the fish canning industry) earned $4,250,894 on an investment of $3,600,409. The wages for miners at Nome are $5 per day and board during the summer, and about $3.50 in winter. Mechanics in Nome and skilled workers in timbering mines and other mechanical engineering earn $1 per hour.——The North American Con. Tin Mining Co. is the title of a new organization effected in New York for the purpose of absorbing by purchase and location many of the large tracts of tin-bearing ground north of Nome. Jos. Sliscovich has begun the preliminary work for installing a 10-stamp mill with which to reduce the ore in his antimony mines on Hobson creek. All of the machinery has been shipped from San Francisco.——The Ault Fraction, lying adjacent to Little creek, five miles from Nome, is exceptionally rich. It is owned by the Pioneer Mining Co., and this winter's production of placer gold will nearly reach $2,000,000. A streak two inches in thickness on bedrock is so rich that it is carefully taken out and shipped direct to the banks for reduction without sluicing.——The Lakeview claim, at the head of Irene creek, has over 12,000 cars of pay gravel on its dump, in which gold can readily be seen with the naked eye. Over a quarter of a million will be cleaned up in the spring.——On Sunset creek the waters have been under control for nearly three months, and at least half a dozen of the operators have taken out big dumps of rich pay dirt.

Nome, March 28.

ARIZONA.

COCHISE COUNTY.

During last week the 125-ft. addition to the Copper Queen smelter was completed. The addition is now ready and the building is thus enlarged so that two more 500-ton furnaces can be accommodated whenever there is a demand for their construction. The 50-ft. addition to the power-house has also been completed and all the new machinery is now in place. This new power will be sufficient to supply any additional furnaces which may be decided upon in the future. The new ore-bin which was recently excavated alongside the original ones is now ready for the cement lining, but just when this work will be started is not known. An additional casting and elevating machine is now being installed. The machine receives the copper from the converter stands and delivers it onto the platform in bars ready for loading into the cars. The molds are arranged in a circle and are carried under the converter spouts automatically. The Queen production for the month of March was about 7,500,000 lb. copper, an increase over the product for the short month of February. During the present week the water from the artesian well in the valley west of the smelter was brought to the works, and is for the first time being used. This well was bored two years ago and a flow of 200 gal. per min. was encountered.——The Superior & Pittsburg Co.'s annual report for 1907 is issued. The company produced 9,691,405 lb. copper from ore which yielded an average of 73.84 lb. per ton, or 3.69%. During the year the company's expenses exceeded income by $1,067,640, the report showing an excess of liabilities over assets of $515,937. A total of 23,332 ft. of development work was done, and some valuable ore was developed.——Miami Copper Co. is the name of a new firm which has been floated by the Lewisohn-General Development interests. The company has a capital of $3,000,000, divided into 600,000 shares. One-half of this stock is owned by the General Development Co., which purchased and has extensively developed the Miami property. Of the treasury stock 200,000 shares will be offered to the public at $5 per share and 100,000 shares will remain unissued. The proceeds of the sale of the 200,000 shares will be used for the erection of a concentrator of

Near Prescott, Arizona.

1000 tons daily capacity.——The Miami Copper Co. has developed a large body of concentrating porphyry ore about six miles west of the Old Dominion mine at Globe. It has 2,000,000 tons of this ore in sight which averages 3% copper, and will concentrate 10 tons into 1. It is estimated that the gross cost of producing copper from this orebody will be 9c. per lb. On this basis the company would earn more than $1 per share annually on its issued stock on 13c. copper.——The Raven Mining Co. is putting in a new hoist with capacity to work to a depth of 2500 ft. While the engine was being installed some repairs were being made in the shaft. The Raven shaft is sunk on an incline down to the 1100-ft. station, which is at a vertical depth of about 800 ft. The vein opened at the 800 shows better ore than the 700. It also carries considerable silver and gold.

CALIFORNIA.

EL DORADO COUNTY.

The Gold Hill mine has been sold to N. and T. Douglas. The property is situated 12 miles from Placerville. The vein is large, but of low-grade ore, which can be cheaply treated by quarrying and milling.——At the Alpine mine, the vein has been cut on the 300-ft. level, and cross-cut for a distance of 18 ft.——A 35-hp. engine has been erected to raise water from the ditch to strip off the surface of the Green Emigrant mine. A cross-cut is being run through the ridge from the east, which should strike a rich seam about 30 ft. below the crest of the ridge.——New boxes have been put in the Pond mine at Todds valley. The old drifts will be re-timbered. The old Pond ditch, having its source in Volcano canyon, near the old Hazard mine, will be repaired.——Work will soon be resumed at several

properties on the Forest Hill divide.——The shaft at the Davenport mine, near Georgetown, will soon be sunk to the 100-ft. level by contract.——Two men are working at the Vineyard mine. An adit has been driven 170 ft., and the gravel is now harder. Work will be stopped soon unless rain comes, as water is scarce.——The shaft in the Bellevue in the Ophir mining district is down 400 ft. and cross-cuts begun.——At the Georgia mine, which lies 1½ miles north of Baker ranch, a flow of water was encountered which flooded the shaft. An adit 600 ft. long had been run from Shirt Tail canyon, which was found to be too high to drain the shaft. A branch was driven at 300 ft. from the portal to the east, and a shaft sunk 40 ft. to bedrock. This has been flooded by a stream of water on the bedrock.——About 10 men are working at the Polar Star at Dutch Flat. The cement and gravel deposit occurring here is covered by a flow of basalt.——At the Three Star shaft, near Ophir, work will be carried on at the 200 and 300 ft. levels. The pumps are being removed from the 1200-ft. level.

NEVADA COUNTY.

(Special Correspondence).—The Golden Gate mine has been re-opened. Good ore is coming from the 200-ft. level, where the vein is 18 in. wide. The property is unwatered to the 400 level, where a good body of ore was struck. N. P. Martin is superintendent.——Work continues at the Belle Union, with indications of the near proximity of the vein.——Extensive developments are going on below the 4000 level at the Central shaft.——At the Brunswick considerable ore is coming from the upper workings. The mill is running steadily.——It is reported that work will be resumed on the Sterling mine in Willow valley.——Good ore is being developed at the Delhi mine. H. Eddie is superintendent.——J. Botte has struck some deposits of promising gold ore at the Isolta ranch at Scott's Flat. The veins run from 18 in. to 20 ft. in size, and are three in number. Development will be pushed.——Work is about to commence on the new winze at the Champion mines. ——A new 16-ft. water-wheel has been installed at the Murchie mine. Extensive work is going on in the lower levels.——The Washington district is coming into prominence and much development work is going on in these mines.——Considerable driving is under way in the Magnet in good ore. The property will be opened up to considerable depth. Frank L. McPherson is superintendent.——At the Yuba developments are being pushed and large ore reserves blocked out. Twenty men are at present employed. This number will be largely increased during the spring. ——A hoist is being erected at the breast of the adit in the Mountain View. The vein has been proved for 600 ft.——A limited amount of development work is being done at the Arctic mine.——At the Marcotte mine a cross-cut adit is being driven to intersect the vein at a depth of 350 ft. Good progress is reported.——Some work is going on at the Meister group on Canyon creek.——Work is also going on at the Eagle Bird, Giant King, and several other mines in the district.

Grass Valley, April 6.

(Special Correspondence).—The management of the Idaho-Maryland mine announces that the old shaft will be re-timbered to the 1000 level and a new perpendicular shaft sunk to a depth of 1000 ft. The pay-shoot encountered on the 500 level has been uncovered over 200 ft. Considerable ore is being extracted and 20 stamps are dropping. The mine is looking better now than at any time within the past ten years. Eastern capital is behind the property. Bray Wilkins is general manager.——Cross-cutting at the Posey Canyon is opening up a large body of fair grade gravel.——Good ore has been found in several winzes at the Pennsylvania. The mill is running steadily.——Active exploration and development work is being pushed at the property recently acquired by A. D. Foote 13 miles below this city. The working force has been increased and provision made for systematic developments.——T. K. Richardson has bonded a mining claim on Bear river from J. McManus. The property contains an 8-ft. vein of fair grade ore.——Work is going on steadily at the Bear River mine. The adit is in ore of a commercial grade.——Good reserves of fair grade ore are being developed in the Union Hill. ——Work at the Belle Union is being seriously delayed by caves in the adit.——A new hoisting and pumping plant has been installed at the Ideal mine. Preparations are under way to commence immediate sinking of the shaft. The mine was formerly known as the Lincoln.——A lease has been taken by Nevada City people on a block of ground on the second level in the Mountaineer mine. Several men have been put to work.——The tramway at the Republic is being rushed to completion.——A large force of men are working at the Murchie mine and a large quantity of ore is being handled.——About 30 men were recently laid off at the Champion mine.——The Cold Springs and Buckeye properties are idle. It is reported that work will be shortly resumed.——Several men are working at the Central Consolidated. Good ore has been developed at several points. ——Considerable ore has been blocked out in the Arctic mine, with developments steadily progressing. Martin Vanberg is superintendent.——High grade ore is coming from the Mountain View mine. Several men are employed. ——Extensive prospecting is going on in the Washington district. Several of the old properties are showing well, with numerous claims giving good indications.——Arrangements for the extensive working of the Magnet mine are being made.——The labor situation in Nevada county has manifested much improvement within the past few weeks. ——Mining is unusually active throughout the Grass Valley district. Good reports come from all points.

Grass Valley, April 4.

During the year ending Dec. 31, 1907, the North Star mines produced a total value of $957,816, at a cost for current operation of $398,035, and for development of $93,020, or a total outlay for operating and development of $491,956, leaving an available profit of $445,860. Outlays during the year for improvements, $42,195, and property purchase, $344, amounting to $42,539, leaving a balance of $403,320. Interest earned during 1907 amounted to $22,760, increasing the total net earnings from all sources for the year to the sum of $426,081. Out of this there were paid dividends amounting to $250,000, 10% on the capital stock, leaving a surplus of $176,081. The above stated total was wholly produced from the North Star mine during 1907, and was obtained from 78,366 tons of ore milled, with an average yield of $11.967 per ton, at an average cost of $5.091 per ton for current operation and $1.187 per ton for development, making an aggregate cost of $6.278 and leaving a realized profit of $5.689 per ton over all costs of operation and development. Outlays during the year for improvements and property purchase amount, per ton, to $0.543, leaving a net mining profit, over all outlays, in cash surplus, of $5.146 per ton of ore. The ore tonnage produced in the past year was about 6300 tons less than in 1906, by reason of labor trouble, which interrupted productive operations during January and February, 1907. The value of the output for 1907 considerably exceeds that of any previous year. Of the above stated total, the old or upper workings of the North Star mine, on and above the 2700-ft. level, operated through the inclined shaft, produced 21,211 tons, yielding $296,798, or an average of $13.993 per ton, at an operating cost of $129,037, or $6.084 per ton, and a resulting profit of $167,761, or $7.909 per ton. The outlays for development and exploration in the old or upper mine during 1907 amounted to $35,724, or $1.684 per ton, giving a total cost of $164,762, or $7.768 per ton, and a net mining profit of $132,036, or $6.225 per ton of ore. During 1907 the deep or lower North Star mine, comprising all workings below the 2700-ft. level and operated through the Central vertical shaft, produced 57,155 tons of ore, yielding $641,018, an average of $11.215 per ton, at an operating cost of $269,898, or $4.722 per ton, and a resulting profit of $371,120, or $6.493 per ton. Additional outlays for development and prospecting work in the lower mine during 1907 amounted to $57,295, or $1.002 per ton, making for operation and development together a cost per ton of $5.724, and leaving a net mining profit of $313,824, or

$5.491 per ton of ore. The results of development and prospecting work during 1907 have been satisfactory, both in the upper and deeper levels of the mine. In the deeper levels, now the main source of production, the stopes have continued to yield a somewhat better quality of ore. The developments in the bottom of the mine are especially satisfactory. Drifts have been extended in both directions on the 4400 and 4700 ft. levels. The sinking of the inclined shaft, following the vein downward from the 4000-ft. level, at the bottom of the Central vertical shaft, was resumed Oct. 1, at a point where previous sinking had ceased, somewhat below the 4700-ft. level, and at the end of 1907 this work had reached a depth of 5000 ft. from the outcrop, measured on the dip of the vein, or 2000 ft. vertically below the overlying surface. In this work the shaft was sunk in ore for 150 ft. of its course, disclosing a vein from 3 to 6 ft. thick, of rich quartz, which now promises to be the source of much profit. The production of ore is contributed from the different levels opened in the mine, at depths varying from 1500 to 5000 ft. below the outcrop. The cyanide plants of both mills are in successful operation, treating all the mill tailing with satisfactory results. At the Central plant the cyanide process has been successfully

adapted to the treatment of the concentrate of the mills, yielding better economical results than were formerly obtained by chlorination or smelting.

At Maybert the Yuba mine has 20 to 25 men at work on development, but it is expected that the force will be doubled in about a month.——The Mountain View mine on Canyon creek is being developed under the direction of E. B. Miller, who is driving an adit on the vein at the base of the Devil's Backbone. The vein has proved continuous for 600 ft. and a power hoist is being erected at the breast to enable the continuing of the sinking of the shaft on the inner shoot. That shoot is expected to yield a bonanza. The Mountain View has a complete surface plant, and the mill is capable of crushing ten tons of quartz per day.—— A quarter of a mile farther up Canyon creek is the Arctic group, where Martin Vanberg is doing some development work. Near the top of the ridge, within sight of the Mountain View and Arctic, is the Marcotte, where a cross-cut tunnel is now being driven by contractors to tap the vein at a depth of about 350 ft. At the present rate of progress the vein is likely to be intersected within a couple of weeks. Near Ormonde on Canyon creek, half a mile above its conjunction with the Yuba river, is the Meister group, where several veins are also being opened up by Fritz Meister. At the Magnet good progress is being made in driving the drifts, and it is hoped to thoroughly explore the vein and open the orebody at some depth for overhand stoping. The Eagle Bird, Giant King, German, Old Rainbow, Star, and other mines are also working. The first freight of the season arrived in Washington last week, being supplies for the Diamond Creek gravel mine.

Good ore is being mined on the 500-ft. level of the Idaho-Maryland mine. The old shaft will soon be repaired and sinking continued from the 800-ft. level. It is reported that work will soon be resumed at the Sterling mine in Willow valley. In running the drift to the east a good vein, 18 in. wide, was found.——The Jenny Lind Mining Co. has reached the gravel in the adit at 1463 ft. from the portal, in a raise 28 ft. high. The adit will be continued for 100 ft. and breasting commenced. The blue gravel carries coarse gold.

PLUMAS COUNTY.

It is reported that a deposit of asbestos has been found near Garden Springs, 12 miles from Quincy. The property is about 400 ft. from the Western Pacific track.

TRINITY COUNTY.

The Bonanza King mine, near Trinity Center, will soon increase its force, as the debts of the company have been paid, and the dismissal of the action by the employees is being arranged. A small force of men has been at work since the failure of the California Safe Deposit & Trust Company.

SAN BERNARDINO COUNTY.

A placer deposit, rich in gold and tungsten, is reported as having been discovered near Randsburg, on the Gold Flint claim owned by A. Nixon and W. C. Wilson.

SIERRA COUNTY.

A discovery is reported in the Snow Point mine, a vein more than 4 ft. wide having been cut. The quartz is said to carry arseno-pyrite similar to that found in the Tightner mine at Alleghany, which is about four miles distant.—— At the Rainbow mine, rich ore is being milled, and a large area is now available for development above the lower adit level.——The Wyoming lode in the Deep Blue placer mine has recently been developed by the Dead River Mining Co. The vein was found 1800 ft. from the portal and some rich ore has been extracted.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A night shift has been put on at the Capital mill, and now 70 tons of ore are being treated daily. The force in the mine is being increased daily and a heavy tonnage of smelting ore is being broken. Eight raises are being carried, all of which are up 45 ft. The shoot is still showing, measuring from 12 to 22 ft. wide. ——Extensive work is under way upon the Ramsdell mine on Lincoln Mtn. The east and west drifts are being extended and a body of heavy lead ore is being followed which measures from 18 in. to 5 ft. in thickness. This assays from $10.50 to $32 per ton in gold, silver, and lead. M. Jacoby has been appointed manager.——A compressor plant is to be installed soon at the Golden Glory adit, Saxon Mtn. The bore is now in 600 ft. J. L. Young of Empire Station is superintendent.——Heavy shipments are being maintained from the Doric holdings on Saxon Mtn. Stoping is in progress on the Magnet vein, and a streak of ore is being followed that measures from 1 to 4 ft. across. The average value of the product exceeds $100 per ton. The Magnet M. & T. Co., operating this property, will start extensive work in the near future.——Occasional shipments are being made from the Centennial, situated on Leavenworth Mtn. The adit is being extended and a streak of 4-oz. gold ore is being followed that measures from 4 to 8 in. across. David Kennedy is manager.——Connection from the Burleigh adit with the Seven-Thirty shaft will probably be made within two weeks. There remains only 50 ft. of ground to be broken before the water will be tapped. ——The Everett holdings on Republican Mtn. are undergoing systematic development. The adit has been cleaned

out and re-timbered, and now driving is being carried forward upon a streak of silver-lead ore that is from 8 to 12 in. wide.——The Lebanon group of claims is shipping ore. Maxton Bros., operating under bond and lease, are raising on a streak of ore that is from 12 to 18 in. wide, assaying $105 per ton in silver and lead.——The Smuggler continues to maintain regular shipments. Conti & Co., leasing on the fourth level, are stoping on a 2-ft. body of $90 silver-lead ore. The ground has been opened for 100 ft. and the shoot has been found to be continuous. G. A. Huffman is preparing to sink the shaft 75 ft., which will reach below the level of Clear Creek.——The Terrible is extracting both smelting and concentrating ore. Wood & Co., leasing on the 14th level, are stoping on an 18-in. streak of silver-lead ore that mills about $90 per ton. A big tonnage of milling ore is being extracted and run to the mill-bins preparatory to the starting of the machinery, about the early part of April.——Steady shipments of smelting ore are being made from the Colorado Central. The ore is being mined through the Ocean Wave or sixth level, the streak measuring from 18 in. to 2 ft. across.——M. J. Riley, leasing on the Sunburst, has discovered a new streak of 200-oz. silver ore. The find was made in carrying a raise 30 ft. above the Grant level, and the orebody measures from 2 to 2½ ft. across. The first shipment was made this week and assayed 204½ oz. silver per ton.——The Red Oak M. & M. Co. holdings have been taken under bond and lease by C. H. Poirier, representing a syndicate of St. Louis capitalists. Already work has been put under way. A raise is to be carried from the Sceptre adit to connect with the Sunburst adit, a distance of 370 ft. With this work completed all the ores from the west side of the mountain will find an outlet on the Georgetown side, thus reducing the cost of transportation to a minimum. A compressor plant is to be installed, and machine drills will be brought into use in breaking the rock. It is understood that the purchasers have made a cash payment of $25,000 upon the property, the entire purchase price to be $15,000.——Good ore has been found on the Hercules property, situated on Democrat Mtn. The owner, Robt. Fisher, is driving an adit, and a streak of $65 silver ore is being followed that measures from 8 to 12 in. wide. Stoping is under way and shipments have been started.——The Socrates workings are being cleaned out and re-timbered. It is the intention of E. Cass to drive the adit forward for the exploration of the ground.——Bryant & Co., leasing on the sixth level of the Bellevue-Hudson, still continue to send out weekly shipments of first-class ore, the net returns being $100 per ton in silver and lead. This is proving to be one of the best paying leases of recent years in the Georgetown district.

Georgetown, March 29.

A rich streak of ore has been found on a lease being operated by Butler & Co. on the Wheeling vein through the Tobin adit. The ground has been opened for a length of 100 ft. and for 70 ft. a streak of silver telluride occurs, from 4 to 6 in. wide. The stope is now 40 ft. high and the ore is being sacked.

EL PASO COUNTY.

(Special Correspondence).—During the month of March the Golden Cycle mill, which was rebuilt after the fire, treated 22,167 tons of ore from the Cripple Creek district and sampled 28,096 tons. The normal capacity of the mill will be 25,000 tons. Eight Edwards furnaces, furnished by Chisholm, Matthew & Co. of Colorado Springs, are used for roasting the ore, and five grinders and seven Chilean mills. The company has recently installed a small Jeffrey locomotive for handling coal, which reduces the force from six men to two men. A large percentage of the ore treated in this plant is custom ore. The plant was destroyed by fire shortly after they had started operation last fall, and it was necessary to remove several hundred tons of debris before work could be started on the new buildings. The mill was designed by F. Cazin of Denver and the construction work was under the supervision of C. W. MacArthur. John Tait Milliken is superintendent of the mill.

Colorado Springs, April 3.

LAKE COUNTY.

Pumping in the shaft in Iowa gulch has now reduced the water level to about 500 ft., and ten days or two weeks more will be required to drain the shaft. As soon as this is accomplished, sinking will be resumed and driving commenced.——About 60 men are now employed on the Penn property on Breece hill. Three or four sets of lessees are at work and regular shipments are being made. The Big Six, which adjoins the Penn, has also started work through the Penn No. 2 shaft, and considerable development is going on through the lower levels.

TELLER COUNTY.

A body of good ore has been developed recently at the Portland mine. The find was made between the 400 and 500 ft. levels in the Captain No. 3 stope. The deposit has been thoroughly explored and a large tonnage is blocked out. The lessees on the eastern part of the Lennox and Giddings property, on Tenderfoot hill are reported to have made a good find. The shaft is now down 200 ft.——The find that was recently made on the Mountain Beauty by the Findley Con. Co. is improving. The vein is 4 ft. wide and contains stringers of sylvanite.

IDAHO.

BLAINE COUNTY.

The discovery of a rich deposit of cinnabar is reported from the Hailey district. It is stated that an adit has been driven by J. Dacherl 720 ft. into the hill, and the last 18 or 20 ft. is said to be in rich cinnabar ore. The dimensions of the orebody have not been determined. The property is reached from Hailey by going eight miles to the Nay Aug gulch on Deer creek and about a mile to Panther gulch, and then from one-half to a mile up this gulch.

A 25-hp. electric hoist will soon be erected at the Caledonia mine. The raise to the surface, 75 ft. high, is nearly finished, and has been in ore all the way. The shaft will be 5 by 10 ft. and will be sunk from a point 60 ft. below adit No. 1. Drifts will also be run on the vein.——The oreshoot in the Gray Copper mine has increased to 3 ft. wide. The property is about 1½ miles south of Osborn, between McFarren and Myers gulch.——Good silver-lead ore has been found in the Knickerbocker group at 485 ft. from the portal. A raise has been made 8 ft. in the ore, and shows improvement.——The Coeur d'Alene concentrating plant, which is situated between Wallace and Mullan, will be started again within 60 days. The plant will be enlarged throughout and larger rolls, Wilfley tables, and Huntington mills erected. The capacity will then be about 250 tons per day.——The mill at the Thunder Mountain mine has started work. Development work has shown up some good ore. In the east drift 50 ft. of ore is exposed, and in the west drift 90 ft. has been developed. Machinery has been ordered to sink the shaft.——A large consignment of machinery has been received by the Big Sandy Co. for its elevator, at Newsome.

NEVADA.

ESMERALDA COUNTY.

The Goldfield miners' union has declared the strike at an end, allowing the men to work with non-union miners. By a vote of 90 to 25 it was decided to return to work and adopt the Tonopah scale of wages. The operators refuse any advance above their schedule, which is 50c. per day less than Tonopah, but the miners have returned to work, being glad to bring the labor difficulties to an end.

Exceptionally high grade ore is being extracted on the Little Florence. Work will be rushed to the utmost, as the lease expires on April 26. The company has other promising property which will be exploited. The Little Florence recently had to stop work on the original find, as the deposit went outside the lease onto the Rogers-Syndicate lease. Vertical side and end lines form boundaries of leases.——On the Rogers-Syndicate lease, adjoining, rich ore is being broken, and every effort is being made to hasten the work. The lease expires on July 11, and it is not probable that the lessees will have time to work out

the deposit. A shipment of 9000 lb. from this lease was purchased by the Western Ore Purchasing Co. It assayed 88.67 oz., that is, $1773.40 per ton. Shipments to the Western Ore Purchasing Co. last week were as follows: Rogers-Syndicate, 380 tons; Sandstorm dump, 116; Little Florence, 45; Combination Fraction, 57; Wakeman lease, 22 tons. The Nevada-Goldfield Reduction Works received the following shipments: Daisy, 35 tons; Jumbo, 200; New Western tailing, 158; Rogers-Syndicate, 25; American mills tailing, 35½; J. S. Cook lease, 45½; Central Ore Purchasing Co., 26; Begole Mines Syndicate, 135 tons. The Combination mill treated 630 tons of ore, worth 35 per ton.

NEW MEXICO.

SIERRA COUNTY.

(Special Correspondence).—The Good Luck mine is now operating with 30 men, doing development work. Another body of lead and silver ore was found and the outlook is encouraging. Later on they expect to erect a 100-ton mill to treat the ore from the mine. The ore runs high in lead and silver. About 900 ft. of development work has been done in ore. J. H. Elspass is manager and T. J. McKenna superintendent.

Lake Valley, April 2.

OREGON.

BAKER COUNTY.

(Special Correspondence).—Scott German, attorney for the Oregon Smelting & Refining Co., has returned to New York after conferring with W. S. Keith and the principal creditors of the company. It is stated that satisfactory arrangements for a settlement have been made with J. T. Donnelly, cashier of the First National Bank of Baker City acting as trustee for the creditors. The smelter will resume operations during the coming summer.——At the Columbia mine the new quintuplex electric pump is being installed at the 700-ft. level. For several months all mining has been confined to the levels above the 500, but now that unwatering has been continued to the 700, stoping will commence at once at this level, simultaneously with unwatering to the 900, the lowest level on the property. Since the shut-down of the Sumpter smelter the Columbia has been steadily shipping high grade ore and concentrates to the Tacoma Smelting Co. The low grade ore is being treated at the company's 20-stamp mill and cyanide plant. The mine has a large tonnage of ore blocked out, and has paid over half a million in dividends.——At the Red Boy mine a continuation of the ore-shoot of the Concord vein has been encountered on the blacksmith adit level. It is about 3 ft. in width and averages throughout a length of 80 ft., $40 in gold per ton. No stoping is being done at present, but the 40-stamp mill and cyanide plant are being put in shape for early operation.——The Eastern Oregon Mining Co. is shipping ore and concentrates to Tacoma. Their lower grade ore is being treated successfully at the company's 30-stamp mill and cyanide plant. It is reported that this company has secured control of the Sumpter smelter.——The Buffalo-Monitor mine is making regular shipments to the Baker City sampling works. The ore is high grade, shipments averaging over $100 per ton.——Greenlee & Crawford are making an exhaustive examination of the Imperial G. M. Co.'s property near Sumpter.

Baker City, April 3.

UTAH.

JUAB COUNTY.

Preparations are being made to sink the shaft of the Little Chief mine. The shaft is now down 1000 ft. and will be sunk farther, while development work is continued on the 1000-ft. level.——The May Day will resume shipments soon. A gravity tramway, connecting the May Day mine and mill has been built.——The Gemini Mining Co. has just purchased a 500-hp. electric pump. Rich ore has been developed in a winze below the 1700 level. The pump will be erected on the 1600-ft. level.——An adit is to be driven by contract, 100 ft. in length, on the Montreal group, in the eastern part of the Tintic mining district.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—The Hidden Treasure Gold Mining Co. is operating a two-stamp mill at its mine, 20 miles south of Twisp, and has made some good clean-ups during the past two months. The ore from the mine has averaged over $50 gold per ton.——A body of ore reported to be 8 ft. wide and assaying $54 per ton has been encountered in an adit on the Methow mine, at depth of 200 ft. A drift is being driven on the vein.

Loomis, April 2.

STEVENS COUNTY.

(Special Correspondence).—Ore is now being shipped from the First Thought mine to the Trail smelter, at Trail, B. C. The ore has been sent to Northport, Tacoma, and Sullivan Mines smelters. It is rumored that another new shoot of ore, richer than any previously developed, has been discovered on the 300-ft. level. A six-drill Sullivan compressor has been purchased for the mine, and an order has been placed for Sinclair and hammer drilling machines, to be used with ⅞-in. steel.——Two carloads of ore from the Seal and Queen claims shipped to the Tacoma smelter about two weeks ago asasyed 120 oz. silver per ton. A new body of silver ore has been found on the 300-ft. level of the Queen. This property is situated at Springdale.——The Scotia Mining Co. is cross-cutting from the adit on the Scotia group, on Toulon Mtn.——A new strike of gold ore has been reported from the Mountain Chief, a claim recently staked on Toulon Mtn., near the Trojan group.——The streak of high grade ore in the Railroad mine has increased to 4 ft. in width.——It is reported that a rich find has been made in the Globe mine, on Toulon Mtn.——Several mines that were producers of only silver ore are to be prospected at greater depth for copper. Among them is the Eagle mine, which 20 years ago yielded $150,000 silver.

A New Mining Camp.

Spokane, April 1.

CANADA.

ONTARIO.

During last week the City of Cobalt was added to the list of new shippers. Another car of concentrates from the Cobalt Central mines will be sent to the smelter at Sudbury this week. The stoping in the second level of the Big Pete mine has now made sufficient progress to enable the managers to supply a better class of ore to the concentrator, with the result that the yield of silver is showing a steady increase, with a corresponding gain in earnings.

MEXICO.

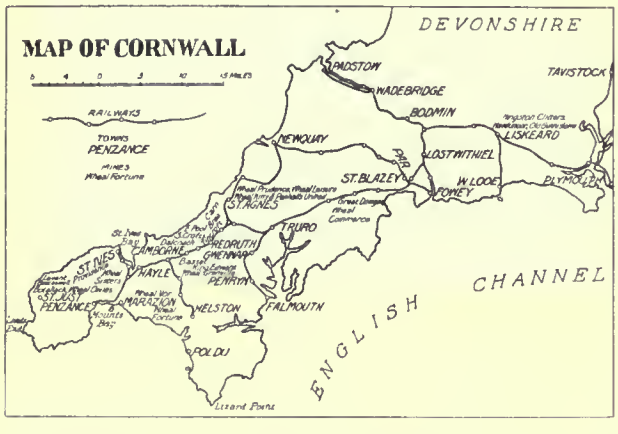
The Moctezuma Copper Co. will soon be ready to put the new concentrating mill in operation. Already some of the machinery has been given a test and it was found to be in perfect condition. In the new power-house all the machinery is in readiness. The new mill will have a stated capacity of 1500 tons per day.

Special Correspondence.

LONDON.

Treatment of Complex Ores. — Elmore Process. — Nundydroog Mine.—The Lancefield.—Hall Smelting Co. and the Le Roi.

The progress at Clitters United has received an unpleasant check and the shareholders are to be asked to put up some more money. This mine is in East Cornwall and was re-opened more than seven years ago by Messrs. Allen, Schiff, and Dietzsch, whose aspiration it was to show that by using recently discovered processes it was possible to successfully treat the complex Cornish ores which had proved unprofitable hitherto. I have frequently referred to this subject, but it is desirable again to say that the ores in question contain tin, wolfram, arsenic, and copper. The Clitters and the adjoining Hingston mine were known to be rich in these substances, and to promise a recompense to those who could separate them. The company has an issued capital of £160,000, and a debenture debt of £18,800. The dividends paid so far consist of 6¼% for 1906, and an interim dividend for 1907 amounting to 2½%, paid last July. At the time that the latter dividend was paid the prospects looked satisfactory enough, and the troubles that have since cropped up were quite unanticipated. The chief trouble has been the access of water into the lower levels of the Hingston mine, which has prevented the extraction of the richer ore as well as caused great expense in unwatering. Then the company has had difficulty in connection



with the electric pumps, which seems to be general in Cornwall. Considerable sums have been spent in this direction, and new plant is now under erection. The fall in the price of metals, as well as the lower grade of ore that has had to be worked during the last few months, since the better ore has been under water, have affected the profits, and the directors feel bound, in order to put the company in a sound financial position once more, to ask for more capital. They therefore propose to issue 160,000 new priority shares of five shillings each, to be offered to shareholders pro rata. There is no doubt that shareholders will respond.

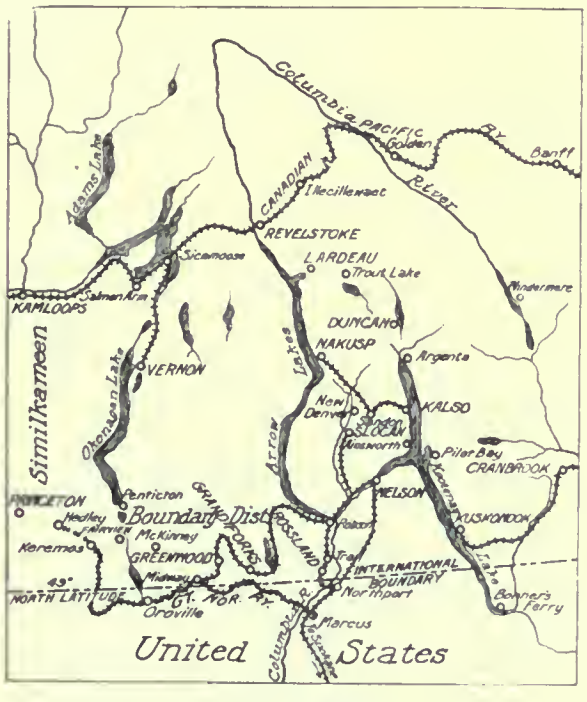
It is of interest to give some particulars of the work done at Clitters during the year 1907. The ore treated was 20,634 tons and the recovered concentrates were as follows: Tin concentrate, 122 tons, valued at £13,678; wolfram, 62¼ tons, value £8614; refined arsenic, 242 tons, value £6883; and copper residues, 180 tons, value £581. The satisfactory state of the arsenic trade has induced the directors to buy ores from neighboring dumps, such as those at the now abandoned Great Devons Consols mine, and negotiations are in progress for the acquisition of 30,000 tons of this material. It is intended to erect a modern arsenic refinery specially designed by T. C. Cloud. There is some intention also of purchasing complex ores from other mines for treatment by magnetic separation. The directors state that the Elmore vacuum plant recently erected has not so far proved a success. I would respectfully suggest that the process is not likely to succeed in the way it is now being used. In fact there is no object in using it at all unless it is used in the way the inventor intends. As it is, the directors are using it in such a way as to reduce the royalty to a minimum and not with a view of the highest recovery. My own experience with the plant shows that it should be used to remove the pyrites from the tin and wolfram. This means that the whole of the ore should go direct from the stamps through the vacuum plant. Consequently the whole output would be subject to the inventor's royalty. In order to prevent this, the separation of the pyrites is done as far as possible on tables, and only the secondary products go to the vacuum chamber. In this way the royalty is reduced, but the expenses are increased, and the methods of separation duplicated, besides considerable losses incurred in the water concentration.

The Nundydroog mine, one of the Mysore group of mines managed by John Taylor & Sons, continues to open up well, and is in as satisfactory a condition as at any time during its twenty-five years of life. Mr. Thomas Richards, a good Cornishman, has been manager for more years than I can remember, and his knowledge and opinions of Mysore mines are unrivalled. His view of the developments at the 2000 to 2300 ft. levels is that the probabilities of a plentiful supply of ores are very encouraging. During the year 1907 the reserves increased considerably, and are approximately eighteen months ahead of the mill. The production of gold for 1907 was 74,964 bullion ounces, valued at £283,138. Of this amount 66,696 oz. were obtained in the stamp battery from 84,000 long tons of ore, and 8268 oz. were obtained from 83,970 tons of tailing. The net profit was £128,749, of which £99,050 has been distributed as dividends and £18,000 applied to capital expenditure. The total production of gold since 1882 is 773,767 standard ounces, valued at £3,015,711. The first few years did not produce much gold, and it was only in 1888 that the returns were in any way substantial, the yield of that year being 6728 standard ounces from 3887 tons of ore. Since then the amount of ore treated and the yield have gradually increased and the increase has been steady except during the years 1898 and 1899, when there was a temporary decrease in the output. As with the Mysore Company, referred to last week, so it is to be in the future with this company with regard to the outlay on new capital expenditure. Instead of issuing new shares whenever new special expenditure is embarked on, the directors intend in future to depend entirely on the profits. Hence we see the item of £18,000 mentioned above. The dividends for the four previous years were over the £100,000 mark, but in those years nothing was put by for capital expenditure. Another new departure in connection with the finance of the mine that is of considerable interest is that in future a certain portion of the profit in each year is to be set aside for distribution in the form of a bonus among the directors, managers, and staff in India and London.

It has been decided by the shareholders of the Lancefield Gold Mining Co. to agree to an assessment of two shillings a share in order to provide additional plant. The Lancefield mine is situated in the Mount Margaret goldfield of West Australia, and the company was floated in London over three years ago by Bewick, Moreing & Co. The property consists of large deposits of what is known in West Australia as low-grade ore, running $8 to $10 per ton. When the orebodies were opened out they did not appear to present any metallurgical difficulties, being oxidized ores at the surface and sulphides below. A 50-stamp mill and a cyanide plant were erected, and at first all went well. It was found, however, that the ore was more difficult of treatment than was expected, and as developments went on the ore became more refractory. It was considered best therefore to alter the system of treatment, and a system of dry-crushing, roasting, and filter-pressing was adopted. The new plant was designed to treat 9000 to 10,000 tons a month and there was no reason to suppose that the extraction and profit per ton would be much different from those at Great Fingall or Sons of Gwalia. A 30s. extraction was figured on, with total expenses of 21s., which would have meant a very good profit. A second unanticipated difficulty was now met with, for the ore proved more troublesome than at the other mines, and the time occupied in treatment was so

much longer that the plant can only deal with 5000 to 6000 tons a month. For one thing, the presence of arsenic in the pyrites makes the roasting more tedious, and secondly the ore is so hard that the capacity of the grinding mills is considerably reduced. The cost of treatment is considerably higher and the profit nearly extinguished. The only plan for reducing costs was to increase the output, and for this purpose the directors proposed to build additional plant. Efforts were made to provide for this plant without having to approach shareholders, but this was impossible. It is hoped that by the expenditure on this additional plant, by which the output will be increased to 10,000 tons a month, the costs of treatment will be reduced to 23 or 24 shillings. If the extraction is 30s., a very fair margin of profit will be left.

The official account of the collapse of the Hall Mining & Smelting Co., operating at Nelson, B. C., has just been published. The directors are very severe on Robert R. Hedley, who was smelter manager up to a year ago. They state that he did not understand the working of the Huntington-Heberlein process, which was started in the autumn of



British Columbia.

1906, and that consequently he made the cost of smelting lead ores three dollars more than before. They also accuse him of over-estimating the contents of the stock of ore on hand, and of passing more ore through the furnaces for every ton of metal extracted than he showed in his returns. This state of things caused the banks to stop the loans, so that the buying of ores had to be suspended. All the ore on hand was smelted in the hope of saving the financial position of the company, and attempts were made to issue prior lien bonds, but without avail. There was nothing for it but for the debenture-holders to step in and take possession. Negotiations are now being conducted with a view to leasing the smelter and the mines. It is doubtful, however, whether anything can be done during the present depression.——The Josie mine, belonging to the Le Roi No. 2, continues to produce ore and is now looking better than ever. Four years ago Messrs. Alexander Hill & Stewart, in taking over the management of affairs, considered that there was a possibility of the mine lasting eighteen months. Since then, owing to careful exploration work, many additional veins, passed over by previous owners, or discovered at first hand, have been opened up, and at the present time there is sufficient shipping ore to last three years at an average extraction of 2000 to 2500 tons per month. During the year ending September 30 last the shipments were lower than usual, owing to labor troubles; 17,828 tons were shipped, containing 12,602 oz. gold, 13,393 oz. silver, and 539,000 lb. copper, the average being 14 dwt. gold and 1.5% copper. In addition to the shipping ore, there is a large amount of concentrating stuff, of which 11,840 tons were treated. This ore averaged 1.6 dwt. gold, 0.16 oz. silver, and 0.396% copper. Concentrates to the amount of 706 tons were obtained, averaging 18.6 dwt. gold, 0.859 oz. silver, and 1.22% copper. Sufficient profit was made to warrant £12,600 being distributed as dividend. A very interesting item in the history of the Le Roi No. 2 is the satisfactory way in which an additional property is turning out. This is the Vancouver mine at Silverton, which was acquired in August, 1906. Before that time the property had yielded the previous owners 923 tons, for which they received $76,380 from the smelters. During the last 18 months up to Jan. 31, 132 tons of picked lead ore, assaying 92.3 oz. silver, 34% lead, and 14% zinc, have been shipped, also 1100 tons of lead concentrates assaying 117 oz. silver, 60% lead, and 11% zinc. The total receipts for ore and concentrate were $119,030. The concentrating ore averages 13½ oz. silver, 3.7% lead, and 4.7% zinc. There is not much trouble in concentrating by ordinary water methods. The mine is so promising that it is to be floated as a separate company, the capital of which is to be £100,000. Of the shares 30,000 are to be offered for subscription, and the money so raised is to be used in providing additional plant. The Le Roi No. 2 company also owns interests in Queensland, having shares in the Cloncurry Syndicate. The first dividend from this source, amounting to £4425, was received the other day.

SALT LAKE, UTAH.

Injunction in Smelter Smoke Case Suspended.—Citizens Celebrate Court Decision.—New Plant for Ohio and Yampa Companies.—Ontario Drainage Tunnel.

The United States Smelting, Refining & Mining Co. has won a great victory in the Federal Court here through an order of Judge John Marshall suspending the injunction against the operation of its lead smelter at Bingham Junction. The order of suspension came as a result of the hearing during the week on the application of the company for a modified decree which would permit it to operate its lead smelter again under certain restrictions set forth in the application. The hearing lasted for three days and a large number of witnesses gave testimony of a technical character to substantiate the claim of the company that its engineers had made such metallurgical triumphs that no doubt remained that the noxious substances contained in the fumes, which had been responsible for the damage done to vegetation in the past, could be conserved by being introduced into bag-houses, and there subjected to processes which would completely eradicate the poisonous elements. The attorneys for the farmers who had banded together to fight the smelters in the now famous smoke cases made a vigorous objection to the granting of any concessions whatever to the company, notwithstanding that they had already agreed to a stipulation which permitted the American Smelting & Refining Co. to operate its lead smelter at Murray. This fact unquestionably aided the U. S. R. & M. Co. materially in getting its proposition again before the court. Judge Marshall made reference to it in his opinion, which was given orally, and stated that the terms under which the American Smelting & Refining Co. was permitted to operate were more liberal than those requested by the competing company in its application. The court indicated also that had the United States company made the showing in the previous hearing of the case that it did this time, no injunction to put the smelter out of business would have issued.

Inasmuch as the injunction has not been dissolved, but merely suspended, it is of course necessary for the United States company to demonstrate further that no damage will be done in the future. Officials of the company declare they know this can be done. Under the restrictions mentioned in the application, the smelting company must absolutely stop all solids, including arsenic, sulphuric acid, copper, lead, and antimony dust, and may emit from the

flue only three-quarters of one per cent sulphur dioxide gas to the total volume of smoke. The restriction will limit the amount of sulphide ores that may be treated, but this restriction will be on the basis of the gas sent out rather than of the tonnage used.

The result of the controversy has been received with a good deal of satisfaction by the mining and business fraternity in general, while officials of the company have received a flood of congratulations. The citizens of the town of Bingham Junction went wild with enthusiasm when the news from the court-room was announced. Amid the blowing of whistles, the ringing of bells, and keeping time to the music of the village brass-band, men, women, and children paraded the streets in joyous hilarity, as it meant the re-employment of men who had been without work since the smelters were closed in the early part of January. The resumption of work at the lead smelter alone will mean the employment of about 750 men and a payroll of $75,000 monthly. While nothing officially has been given out to that effect, it is likely that steps will shortly be taken to obtain similar action which will permit the operation of the copper smelter again. Not long ago the U. S. company offered to pay the farmers a bonus of $90,000 if they would enter into an arrangement similar to that effected with the American Smelting & Refining Co. This was refused, the farmers wanting more. Under the suspended injunction the company will not be obliged to pay tribute. It cost the American Smelting & Refining Co. $40,000 bonus money to make peace with the farmers, besides other sums paid to individuals instrumental in bringing about the deal.

During March the Utah Copper Co. treated in its Garfield and Copperton mills an average of 5000 tons of ore daily, thereby breaking all previous records. The tenth section of the Garfield concentrator will probably be in service within ten days.——Local shareholders of the Ohio Copper Co. are much disappointed over the slow progress being made toward the financing of that enterprise. Advices from Boston indicate that the plan to consolidate the Ohio and Bingham Consolidated companies has not been successful. The Ohio is regarded as one of the best copper mines in Bingham, and engineers estimate that 20,000,000 tons of ore are actually blocked out in the mine. The control of the company is vested in F. Augustus Heinze, and his downfall has seriously interfered with plans which included the installation of a concentrating mill with capacity sufficient to treat 2000 tons of ore per day. The steel building is finished and the equipment for it has either arrived in camp or is hung up at Bingham Junction, where 25 cars of mill machinery are awaiting disposition.——The Yampa Smelting & Refining Co. of Bingham, Utah, recently placed an order with the Allis-Chalmers Co. for plant, consisting of two electrically operated converter stands, with six converter shells, the converter dimensions being 84 by 126 in. The order included a cross-compound blowing engine for supplying air-blast to the converters, electric motors, a complete silica-crushing plant for converter-lining, tamping machinery, cars, ladles, and moulds. Practically all this material has arrived at its destination, and construction of the building in Bingham canyon is in progress.——Ore shipments from Park City last week amounted to 653 tons, the distribution being as follows: From the Daly Judge mine, 240 tons; from the Silver King, 360; and from the New York Bonanza, 53 tons. It is expected that the new zinc plant at Park City will be started by the end of the week on middlings from the Daly Judge mill, beginning its career by treating 50 tons per day. The Daly Judge Co. has between 12,000 and 15,000 tons of this material which has been contracted for by the builder of the works, the Grasselli Chemical Company.——Splendid progress is being made in the restoration of the Ontario drainage adit. The water in Ontario No. 2 shaft will be lowered to the 1400-ft. level within a week, leaving only 100 ft. more to be drained to reach the adit level, which should be accomplished before the close of the present month. The water is being drawn off through 13 holes drilled through the main avenue from a parallel drift. The average length of the drill-holes is about 30 ft.——Ore shipments from Tintic last week amounted to 67 carloads, the contributing mines and amounts being: Centennial Eureka, 49; Bullion Beck, 6; and Eureka Hill, 12 cars.——On the resumption of operations at the United States lead smelter the following companies in the Tintic district, which had their output contracted to that concern, will be requested to resume shipments; namely, the Grand Central, Mammoth, Lower Mammoth, Colorado, Beck Tunnel, and Uncle Sam Consolidated. ——Articles of Incorporation of the Boston-Sunshine Gold Mining Co. have been filed with the Secretary of State, the basis being the Sunshine mine and mill in Tooele county. A. W. Chesterton of Boston is president and John Dern of Salt Lake vice-president.

ROSSLAND, BRITISH COLUMBIA.

Ore Shipments.—Operations at the Granby.—Big Output.—Consolidations.—Sullivan Group.

Rich gold-bearing quartz is still being taken from the lower levels of the Le Roi and Consolidated properties. They are shipping about 850 tons of this ore per week from the War Eagle. A recent shipment of 200 tons averaged $55 in gold.——Shipments from Rossland for the week ended March 28 amounted to 5966 tons. For the Slocan and Kootenay the shipments were 1969 tons. The smelter receipts at Trail were 5467 tons, and at Northport (Le Roi), 1950 tons.

The Granby shipped 27,288 tons of ore during the week mentioned above, which, it will be noted, is the largest weekly shipment they have made up to date. The totals for the year now run 246,796 tons mined and 239,587 tons smelted. The tonnage shipped during March exceeded the 100,000-ton mark, which was the largest in the history of any copper mine in Canada. Owing to the expensive fixed charges at the smelter and mines, it is more economical for the Granby to operate, even with copper at its present low price, than to remain idle.——A fresh rumor was going the rounds the other day that the Consolidated Co. would soon absorb the B. C. Copper and Dominion Copper companies. This is denied by J. E. McAllister, of the B. C. Copper Co., who states that they will resume operations on their own account as soon as the price of copper rises.

The mine and smelter of the Sullivan group are in the hands of the sheriff at the present time; the Crows Nest Pass Coal Co. has taken action for $7000, which this company owes for coke, and liens to the extent of $20,000 have been filed by the men who worked at the mine and smelter. A. I. Goodell, the superintendent, has instituted proceedings to recover $10,000 for breach of contract. Despite this tangled state of affairs, it is stated that work will be resumed immediately. Thirty men are now working at the Hewitt. There is considerable milling ore in reserve. The assets of the Pioneer Mining Co., owning the Black Prince, Bank of England, and other claims, have been sold at auction to a Nelson syndicate. Hard iron oxide ore, shot through with native silver, has been cut in some of the old upper workings of the North Star. The Victor-Silver Leaf group, near Fort Steele, is improving as work progresses. This property is owned by Spokane people. The clean ore carries from 40 to 50 oz. silver and 76% lead. Iron pyrite in the ore carries from $10 to $12.60 in gold.——Twenty tons per day of $60 to $100 copper ore are being taken from the Ikeda mines by the Japanese operators. When new machinery, now on order, is installed the output will be increased to 50 tons per day.

The two most important producers in this district are the Le Roi and Le Roi No. 2 mines. The Le Roi, situated on the southern slope of Red Mountain, within the limits of the city of Rossland, B. C., was located in July, 1890, by two prospectors, who also staked the Centre Star and War Eagle claims. E. S. Topping of Trail recorded the group for them and received as compensation the Le Roi claim, which up to this date has proved to be the richest piece of ground on the property. The Le Roi, consequently, cost Mr. Topping $12.50, and in November of the same year he bonded the property to a Spokane syndicate,

receiving $16,000 in cash as the first payment. The purchase by the present English interests, controlling the mine, involved a cost of $3,750,000 for the stock, at the rate of $6 and $8 per share. The first division of profits earned from the product of the mine was made in 1896, amounting to $25,000; up to the present time the dividends paid to the shareholders sum up approximately $1,345,000. Shipments of gold-copper ore from the Le Roi mine during the last four years have been as follows:

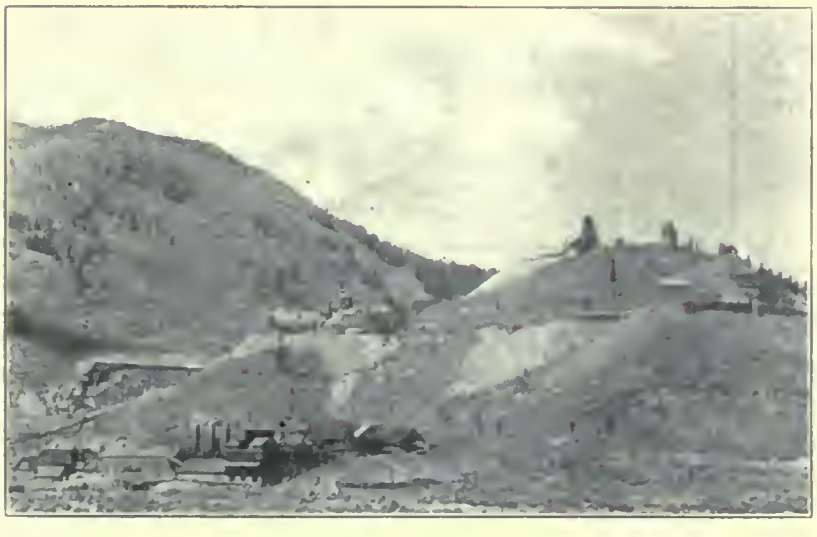
Year.	Tons.	Average value per ton.
1904	160,110	$10.94
1905	114,960	12.41
1906	110,042	12.37
1907	131,696	10.49

The cost of mining and treating this ore was:

	1904	1905	1906	1907
Ore production	$ 2.65	$ 2.78	$ 2.84	$ 3.00
Exploration and development (amount written off)	0.94	0.90	1.26	0.84
Depreciation on mine account	0.21	0.34	0.36	0.20
Smelting and marketing (direct and indirect), including freight, interest, depreciation of plant, etc.	6.77	6.06	6.04	5.98
	$10.57	$10.08	$10.50	$10.02

The average ore carried 0.29 oz. gold, 0.44 oz. silver, and 0.98% copper.

Development work done during last year cost per foot:



Red Mountain, Rossland, B. C.

Raising, $41.99; winzing, $41.34; cross-cutting, $14.88; driving, $15.71; diamond-drilling, $2.79.

While the orebodies worked during the year were extensive, the value of the ore was about 15% lower than of the ore mined during the previous year. The ore is of higher grade in narrow veins in this camp, but runs low in the large lodes. The principal development work done in the mine during last year was the deepening of the main five-compartment shaft from the 1350 to the 1650-ft. level and the sinking of a winze from the 1650 to the 1750-ft. level. The work done on the shaft cost $49,545. The claims controlled by the company in this camp are the Le Roi, Le Roi Fr., Black Bear, Durham, Tat Fr., and Treadwell. In the report of the directors for the year ended June 30, 1907, the balance in favor of profit and loss after payment of dividends and provisions for various contingencies is £3582 4s. 5d., or a surplus of $17,408.52. The amount of £22,690 15s. 8d. was written off for exploration and development and the sum of £7766 13s. 7d. was written off for depreciation on machinery, plant, and surface improvements. A dividend of 2s. per share, from the profits of 1906, amounting to £20,000, was paid during the year. The liabilities are shown as £45,329 12s. 7d.; liquid assets, £119,589 11s. 11d., showing a surplus of assets over liabilities of £74,259 17s. 4d. The smelter at Northport only worked 154 days during the year, part of the ore having been smelted at Trail. The quantity of matte shipped to the refinery from Northport was 753 tons, of a net value of $339,036.30, equal to $450.24 per ton. On June 30, 1907, they had 900,000 lb. of copper in transit, which was sold on a falling market.

During the year 17,828 tons of ore were shipped from the Le Roi No. 2 mine, of the Le Roi No. 2 Ltd., which was a much smaller output than for the preceding year. This was due to several causes, chief of which was the exceptionally severe winter and the prolonged strike of the coal miners at Fernie. The Vancouver mine has developed satisfactorily during the year, and the directors feel that the time has now come for this property to be dealt with as a separate concern. The company's interest in the Cloncurry Syndicate has resulted advantageously, and since the date of the balance-sheet a dividend amounting to £4425 has been received from this holding.

During the last year a little over 130 ft. of development work has been done. This includes work on the Mayday adit, and in a new adit high up the hill which is called the West Poorman. The work on the Mayday has revealed a small quantity of easily broken pay-ground, and the West Poorman adit opened up a promising streak of ore from 2 to 3 ft. wide assaying about $20 per ton. Toward the end of the year the Hamilton vein was found on the 300-ft. level in the unexplored region between the tramway and the porphyry dikes. This discovery was the direct result of the appearance of stope 32 above the 500-ft. level. The ore found is of a good shipping grade, and during the next 12 months regular shipments will be made from the Hamilton vein on this level. A considerable amount of driving and raising has been carried on close to the shaft on the 400-ft. level.

On the 900-ft. level the Hamilton vein has been found west of the tramway dike, and has shown good ore for a distance of 90 ft., after which the ore became scattered and work was suspended. This work will be resumed just as soon as the necessary information regarding dip and strike is forthcoming as a result of the work on the 700-ft. level. In the meanwhile stoping operations on the short streak opened up are resulting favorably. An average sample taken from this stope in October, 1907, went $20 per ton. In addition to the work done on the Hamilton vein, the southerly cross-cut was extended over 300 ft. The direct result of this work was negative, but diamond-drilling has revealed the presence of valuable ore some 320 ft. below. The depth of this ore below the collar of the Josie shaft is 1150 ft., which is the deepest point at which ore has been found on the property. During the year 2537.7 ft. of driving and cross-cutting was done, and 255.4 ft. of raising. This work cost $40,713.21, or $14.57 per ft. During the year 5088 ft. has been bored by the diamond drill. Probably the most important result of this work has been the development of the Hamilton vein on the 300-ft. level. The diamond drilling cost $13,272.20, or $2.61 per ft., as compared to $1.86 per ft. last year. The increase in cost is largely due to the increased cost of carbons, but higher wages have also added considerably. The result of the unwatering and sampling of the No. 1 mine has not so far been satisfactory. The task of prospecting the No. 1 is being continued with diamond drills.

The production during the year was 17,829 tons of shipping ore and 11,840 tons of concentrating ore, and 3400 tons left broken in the stopes, making a total of 33,069 tons. The total stoping costs for the year amount to $123,787.48, showing an average on above tonnage of $4.40 per ton, and

diamond drilling has cost $13,272.23, or $0.48 per ton, in all $4.88 per ton. There has been written off for depreciation $53,849.52, averaging $1.92 per ton. The total costs, therefore, per dry ton mined, are $6.80 per ton. Of 17,826 tons of shipping ore sent to the smelter during the year, the gross value was $21.90 per ton. The total smelting charges on the ore, direct and indirect, were $6.12 per ton.

MEXICO.

Mexican Railroad Nationalization.—Consolidation of Harriman Railroads.—Smelter at Tapalpa.—Mexican Mines' Prospects.

The great Mexican railway merger, or the consolidation of the National Railways of Mexico with the Mexican Central Railway under Government control, which was close to accomplishment last year, when the financial depression necessitated its being laid on the table, is again brought prominently into the foreground by the signing in Mexico City, on March 28, of the articles of incorporation of the new holding company, and the election of seven members of the board of directors, who will later choose others to make up the full board of 21, of which number 9 may live abroad and form a local board to sit in New York. Among those selected are Pablo Macedo, a prominent lawyer of Mexico City, who will probably be chosen chairman of the board; Richard Honey, of the International & Mortgage Bank; Joaquin D. Cassasus, former ambassador to the United States, and Guillermo de Landa y Escandon, Governor of the Federal District of Mexico. The organization of the new company was fully outlined in these columns during July of last year, the time of its authorization, but it may be briefly repeated that the company is to be capitalized at $230,000,000 (₱460,000,000), or 2,300,000 shares of $100 par value, of which there shall be first preferred, $30,000,000; second preferred, $125,000,000; and of common stock, $75,000,000. The company is authorized to issue further preferred 4½% mortgage bonds of $231,000,000 and ordinary 4% mortgage bonds of $186,000,000. These bonds carry with them an absolute "guarantee on the part of the Government of the United Mexican States for the punctual payment of principal and interest," and for and in consideration of this guarantee, together with the Government's present holdings in the National Railways of Mexico, the Mexican Government receives outright, without any immediate cash outlay, 1,150,023 shares of the 2,300,000 shares in the new company, giving it the control. As the articles of incorporation provide for the guaranteed payment of dividends from January 1, 1908, for three years, whether earned or not, it undoubtedly contemplates that the complete transfer to the new company will be made in the near future. If the consolidation is followed by as many improvements throughout the whole system as followed on the Government's obtaining control of the Mexican National, the change will certainly be welcomed by everyone in Mexico.

Word also reaches us that all the Harriman roads are to consolidate, which in Mexico means the Sonora, the Cananea, Yaqui River & Pacific, and the Guaymas-Guadalajara line. It is to be hoped such may be the case, for it should hasten a number of much needed cross-connections in the State of Sonora. On the Guaymas-Guadalajara line work is being pushed as rapidly as possible, also from the Guadalajara end, and something over 10 miles has been constructed out from Orendain station on the branch of the Mexican Central. From 600 to 700 men and 100 animals are kept busy, and the 4000 tons of 75-lb. Russian rails and the 35,000 bbl. Russian cement were taken to the Guadalajara end by way of Tampico. Supplies for the western end go to Guaymas.

At Tapalpa, in Jalisco, the Keystone Copper Co. has had a sad experience with the Poehle-Croasdale process of ore reduction, on which the company's good money was spent only to end in failure, so that the same has been thrown out and the small smelter at Etzatlan has been purchased and is being moved to Tapalpa. The company is also experimenting with cyanide on some of its non-copper ores and tailing.——The Mexican Mines Prospects Development Co. is becoming unusually aggressive for a new company. Organized in Mexico City but a few months ago with José L. Riqueña, president of the Dos Estrellas Co., of El Oro, at its head, it has already acquired some 82 pertinencias in the Hostotipaquillo district of Jalisco, known as the San Luis del Oro group; and in Pachuca has taken up the Estrellas de Pachuca and the Gibraltar y Anexas, and those in a position to know say that the properties in both camps are most promising prospects, and worked with the capital and energy with which this company is so well provided, should soon prove profitable.

The Boca del Cobre Mining Co., owning mines at San Luis del Cordero, Durango, has just purchased the Santa Rita, San Francisco, San Nicolas, and El Rosario mines, at Nieves, in the State of Zacatecas. These are developed properties, the Santa Rita having a shaft 900 ft. deep, equipped with a 75-hp. hoist, pumps, etc. On the 800-ft. level a drift 1275 ft. long has been extended, continuously

Mexico.

in ore. The company claims ore reserves valued at ₱2,000,000. A new water-jacket furnace of 120 tons capacity will be ready for blowing in about June 1, using copper as a collecting medium, arrangements having been made with the American Smelting & Refining Co. to supply the necessary copper. The resultant matte will be shipped to the latter company.

Notwithstanding the lack of transportation facilities, considerable activity is noticeable in the vicinity of Toluca, in the State of Mexico, particularly in the districts of Sultepec, Zacualpam, and Temascaltepec, largely due to the power furnished by the Sultepec Electric Light & Power Co., of which the La Quimica y Anexas was the first to take advantage by thoroughly equipping mines and mills with electrically driven machinery. This lead has been followed by the El Rey Mining Co. in the installation of electric hoists and pumps, and now that good ore has been struck in its Santa Ana mine, a 2-mile overhead tram is to be built to connect the mine with its Guadalupe mill, and a complete electrical equipment has been ordered from the Westinghouse Co. through G. & O. Braniff. The Los Arcos M. & S. Co. has temporarily closed the smelter near Toluca, and is making preparations for the erection of a 100-ton concentration and cyanide plant at its mines in the Sultepec district. The Carboncillo in the Zacualpam district has struck good ore and is adding 15 stamps to the mill, though the selected mineral is sent in to Toluca for shipment at the smelters, but this company, instead of installing electrical machinery, is erecting gas-producers and engines at the mill. The Genovesa has also encountered high-grade ore and is shipping to Toluca. The Santa Inez Co. has been organized in Mexico City with a capital of ₱175,000, and the

La Gerardita, with a capital of ₱200,000, for operating on properties in the Zacualpam district, near the Carboncillo.

In the El Oro district of the State of Mexico the Borda Antigua y Anexas is placing electrical equipment throughout at mine and mill, for pumps, tube-mills, crushers, and so forth, making a total of 500 hp., all of which will be from the Westinghouse Electric & Manufacturing Co. The Descubridora has started the cross-cut from its 750-ft. level and the progress of this cross-cut will be watched with a great deal of interest, as all look to it to prove the southern extension of the San Rafael and other important veins of the El Oro district.

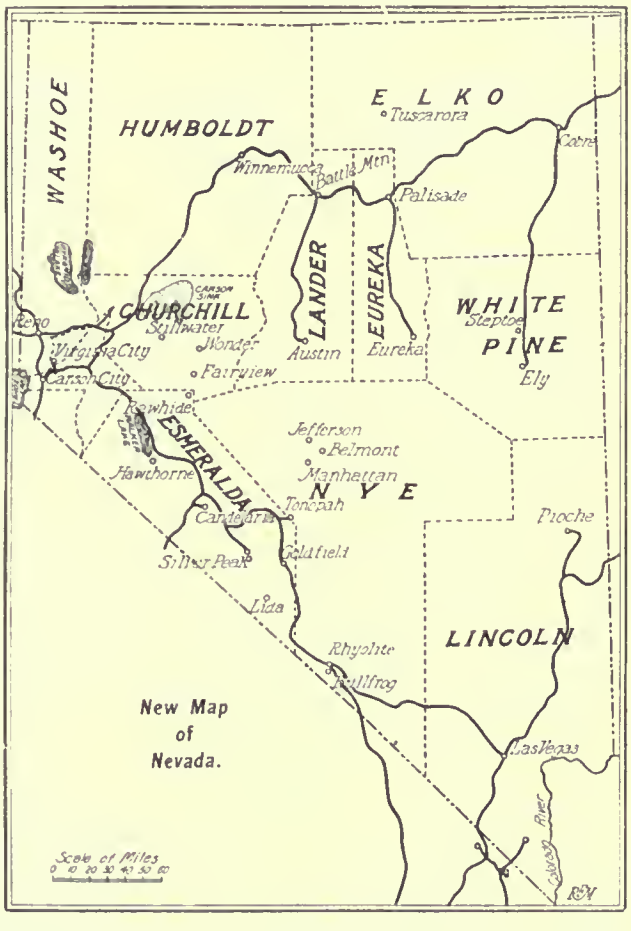
GOLDFIELD, NEVADA.

Rawhide. — Geological Conditions.—Ore Shipments.—Exaggerated Statements.—Fairview and Stimler Camps.

The geology of that part of the Regent district, in Esmeralda county, comprised within the scope of operations of the Rawhide camp is as yet only imperfectly worked out. In general it may be said to be a region of acid lava flows, consisting of rhyolite, or perhaps dacite, often displaying a perlitic structure. The latter type, which is common all over the district, is always extremely acid. On McLeod hill is an exposure of a granular rock, provisionally identified as diorite. On the west side of Balloon hill is a large exposure of kaolinized felsite, the comb of the ridge being sheared slaty rhyolite. Another intrusive coarse granular porphyritic rock is noted on Hooligan hill. No dikes are in evidence, but the country has been extensively brecciated by faulting in at least two directions, approximately at right angles to each other, north and south, and east and west. Little or no silicification followed this faulting. At one point, in the northwestern portion of the camp, faulting has been later than the silicification of the effusive lavas, the brecciation of an older cemented breccia occurring along the same zone as the original faulting. The gold occurs largely in seams, with occasional rich streaks from a fraction of an inch to one inch in width. The deposition of the precious metals does not follow the fault-lines within the brecciated zones, but appears to be quite erratic. It is noticeable that whenever the mineralization has taken place the fine material is richer than the hard quartz. All the stringers of enrichment pan well, but the gold not being fine or flaky, and worth only about $12 per oz., owing to the large proportion of silver in the native alloy, it shows up better in the pan than subsequent assays will sustain.

Up to the present time the most conspicuous properties are the Rawhide Consolidated, the Rawhide Queen, the Townsite group, the Mascot group, and the Royal & Tiger groups.——The Murray lease on the Rawhide Consolidated consists of a silicified zone revealing at the shaft, so far as uncovered, a width of 25 ft. The quartz ore from the dump assayed $24 per ton, of which amount about $8 was gold. Balloon hill belongs to the Rawhide Queen Co., and some good leases are found on the western slope, chief among which are Kearns No. 1 and No. 2, the Butler and the St. Ives leases. Two carloads gave returns of nearly $100 per ton. From some of these lodes very high assays have been obtained, though exaggerated figures have been published. On the south side of McLeod hill is the Miller lease on the Happy Hooligan claim, and on the contact between the diorite and the felsite it shows 3 ft. of good ore, probably worth $25 per ton. This belongs to the Townsite Co. The Mascot claim is located on Grutt hill, and originally yielded some exceedingly rich ore, but later sampling has proved disappointing, the value having dropped, as shown by one careful sampling, to $6 per ton. No well defined veins or silicified zones appear, and the indications are that the ores on this hill will be 'bunchy' and erratic. The Royal claim shows about 5 ft. of crushed country rock, with very little quartz. A seam of gouge on the foot-wall pans well, but a carefully taken sample showed only $12. It is noticeable, however, that contrary to the rule in this camp, the alloy ratio was 1 of gold to 4 of silver by weight. Near to this lies the Bushwhacker claim, on which is the Kirk lease. The outcrop has been opened up, and reveals a 4-in. pay-streak assaying $54 per ton. The camp shows a wide distribution of gold, but not enough has as yet been done to demonstrate the extent to which surface enrichment may have taken place. Altogether the most encouraging prospects would seem to be those on Balloon and McLeod hills, and the Murray lease.

The camp of Fairview is prospering; in the Eagle, on the 200-ft. level a drift is being extended on a vein that has been shown in a number of cross-cuts to average 21 ft. wide; the superintendent says that the average is about $35, and the ore looks like it. This orebody reaches into the Aztec, and is now shown in the Eagle drift only 150 ft. from the latter's end-line. The Hills is doing only development work, and the owners are discussing the erection of a mill. They have over 10,000 sacks of high-grade ore and the mine certainly looks prosperous.——The Stimler district, 8 miles south of Silver Peak, has a series of four or five parallel veins in rhyolite with dikes of porphyry near the foot-wall; these veins traverse a tract 1½ miles wide,



and can be traced on the outcrop for 15,000 ft. The vein material is spar and quartz highly leached by surface waters, the values being one-third gold and two-thirds silver. The gold is free and the silver occurs as a sulphide and as horn-silver. About 25 sets of lessees are at work, and have three shafts over 150 ft. deep; cross-cuts at this level show 26 ft. of ore on the main lode, several feet of which is of shipping grade ($100) or better. The camp is 18 miles by road from the railroad at Blair, and a new road being constructed brings it 10 miles from Blair. It was discovered last summer by Harry Stimler and Henry Jagels, and a three-quarters interest sold to some local mining men for $92,500. I understand a one-third interest has since been sold to some New Yorkers for $300,000. This camp will make good, and from present indications should be a rival to the big company at Blair. There is no excitement nor stock-jobbing nor townsite boom, only mining.——The Kaeding Construction Co. is building a 50-ton mill and cyanide plant for the Ramsay-Comstock Mining Co. at Ramsay, and George L. Kaeding is at Ramsay, personally overseeing the work. This plant will be running in three months.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Location.—There is no State law in California prescribing the manner of locating mining claims.

The ordinary speed to run single-stroke pumps is 100 ft. of piston travel per minute, double-stroke pumps should have 140 ft. of piston travel per minute.

For the successful roasting of zinc ores a higher temperature is needed than for roasting lead and copper ores. Zinc sulphate is formed in the roasting, which is only decomposed at the highest heat of the roaster.

Metallic iron is not found in a copper blast-furnace because the atmosphere is not sufficiently reducing to change the ferrous oxide to metallic iron. Ferric and magnetic oxides should be reduced to ferrous oxide, which readily combines with the ore to form ferrous silicate.

In pyrite smelting, insufficient air blast results in a low-grade product, that is, too much matte. All the oxygen blown into the furnace is used up at once in burning sulphur and iron, and more air is required to effect the degree of oxidation necessary for the greater degree of concentration.

In matte smelting, the amount of sulphur left in a roasted ore determines the amount of matte that will be produced by smelting. The copper in the roasted ore will first take up sulphur to form cuprous sulphide, and after this reaction is completed the remaining sulphur will be taken up by iron to form ferrous sulphide.

Copper slags may be economically removed by granulation. For this a cast-iron launder is arranged to receive the slag, and a good flow of water maintained. In addition a horizontal jet of water is arranged to strike the falling slag, cooling and breaking it up, when it is swept away in the launder to the dump. The launder should have a grade of one inch per foot.

Annual Labor.—It is doubtful if the Act of March 31, 1891, Stat. 1891, p. 219, is in force. It is customary, however, to file proofs of annual labor. A failure to file such proof does not render the claim subject to re-location. Such filing, where authorized by law, is a convenient method of proving prima facie that the work has been done, but it is optional, not necessary, and no penalty is attached for failure to file.

Most of the hard steel at the present time is made in the open-hearth furnace. Enormous quantities are used for car-springs and agricultural machinery, and both the acid and basic furnaces furnish a share. There are, however, some purposes which require a steel free from the minute imperfections often present in open-hearth metal. Such is the case in watch-springs, needles, and razors, and it is found that the old crucible process gives, in the long run, the most satisfactory metal for such work. The process consists of putting into a crucible a proper mixture of scrap, pig-iron, or charcoal and heating it until everything is thoroughly melted, the crucible being kept tightly closed to prevent the admittance of air. This process is a century old, but seems likely to survive for many years longer.

Kerosene should never be used in an air-cylinder, but, instead, fill the oil-cup with soapsuds made preferably of soft-soap, one part soap to fifteen parts water, and feed this into the air-cylinder. Let the compressor work with soapsuds instead of oil for a few hours, or say a day each week. Feed the solution liberally and then open the receiver blow-off and drain off the accumulation of oil and water. This cleaning process should be repeated as often as necessary, the exact intervals depending on the service of the compressor. If running at full capacity for 24 hr. per day, about once every week or two will be sufficient. If on a light load and running for 8 to 10 hr. per day, once every month or two will do very well. The soapsuds can do no harm, but care should be taken to feed with oil a half-hour before shutting down, so that the parts may not be subject to rust, which is the only danger from the use of soapsuds.

Cyanide in Creek.—A mining company owns property in a gulch a mile above town. The company has been operating a stamp-mill for several years, impounding the tailing, but delivering the water into the stream. Residents of the town sunk a concrete cistern to bedrock to get water for domestic purposes. During August and September the creek dries up. The mining company purposes building a cyanide plant, but the owner of the water system objects. (1) Will the water be contaminated, if the pulp is properly impounded? (2) What standing would the owner of the cistern have in court? To these queries we reply thus:

(1) Whether or no the water from the cyanide vats which would ultimately flow to the cistern mentioned would reach the cistern free from noxious elements, would depend on circumstances. If such elements existed in suspension, the filtering through the gravel might and probably would clear it. If in solution, they could not be eliminated without precipitation. If we owned the cistern we would not like to take any chances.

(2) The owner of a water right must so use it as not to injure his neighbors. He would not be permitted to contaminate the water to the detriment of lower proprietors. He might possibly have a right to consume all the water, but this would not permit him to contaminate such as necessarily flowed to lower levels. We think the proprietor of the well could enjoin the contamination of the water under the circumstances stated.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Copper Assay.

The Editor:

Sir—In your issue of March 14 you publish a letter from E. G. Rice, suggesting the use of copper in place of platinum for the electrolytic copper assay. Mr. Rice says: "It occurred to me to use two cylinders of pure electrolytic copper for cathodes, instead of platinum." If Mr. Rice means electrodes, that is, cathode and anode, where he says cathodes, trouble is obvious; for the anode of copper would plate over to the cathode, as in the electrolytic refining process, and the result would be useless.

However, granting that it was the intention to use platinum or gold for anodes, and copper for cathodes only, the scheme is scarcely practical, for it would defeat the high accuracy of the method unless very elaborate precautions were taken. It is difficult to keep copper at anything like the constant weight in a laboratory atmosphere, and in addition the stem, or exposed part of a copper cathode showered for twelve or more hours by the escaping gas bubbles, with the acid electrolyte, would oxidize and crust and change enough to make the work unreliable. Again, it would be necessary to pickle, rinse with water and alcohol, dry, and weigh just before each solution was put on the battery. The theory is all right, just as it is with aluminum, but an intimate acquaintance with the electrolytic method convinced me that for satisfactory reliable work, where speed and accuracy are required, platinum (or gold) is necessary.

The successful use of stirrers in electrolytic analysis has made one pair of electrodes do as much work as five or six when the electrolytes are not circulated, so that an ample electrolytic outfit is not now so very costly.

Isabella, Tennessee, March 16.

Mine Fires.

The Editor:

Sir—In your issue of March 28, W. O. Snelling suggests the use of sulphur dioxide in combating mine fires. While I am not aware that it has been generated for the express purpose of producing an atmosphere that will not support combustion, it is used in this way in the case of fires in sulphide ore-bodies, where the so-called 'plenum' system of ventilation is employed. In this case fans blow air into the mine, and these are regulated so as to force back the sulphur dioxide and other products of combustion into the fills or crevices, and thus keep a neutral atmosphere in the fire zone and a supply of fresh air in the workings. The system proves only partly successful, and, while making it possible to work the mine, it does not put out the fire. The gas may not be sufficiently concentrated, but in my experience of mine fires, the intense heat altogether reverses the position of the air and sulphur dioxide in the drift, and the hot gas will be found at the top of the opening and the cold air beneath, while the stopes may have an up-draft and the raises be like a furnace-flue. In copper mines, damp rotting timber impregnated with sulphide dust is spontaneously combustible, and the chemical reactions are so violent that it is difficult to compare this experience with that of gob fires in coal mines. In the former case, it has been found that a little water tends to increase the fire, probably because chemical reactions are stimulated and the water dissolves the crystallized sulphates, and opens passages for the ingress of air currents. The intense heat of rock masses in mine fires is not generally realized. In sulphide mines I have observed rock temperatures exceeding 800°F, and the fine ore will burn as it falls through the air. At the Homestake mine, ore was mined at a red heat, at a temperature said to be about 1500°F. In the latter case, even the heat would cause currents of air and gas that would require careful consideration, and there is little doubt that the question of flooding a mine with any gas involves serious difficulties.

D. F. CAMPBELL.

San Francisco, March 30.

Winter Phenomena in Siberia.

The Editor:

Sir—I send you herewith a brief description of recent phenomena that occur here under favorable conditions. We recently witnessed an occurrence similar to that recorded by myself last winter, which you labeled 'Mock Suns.'

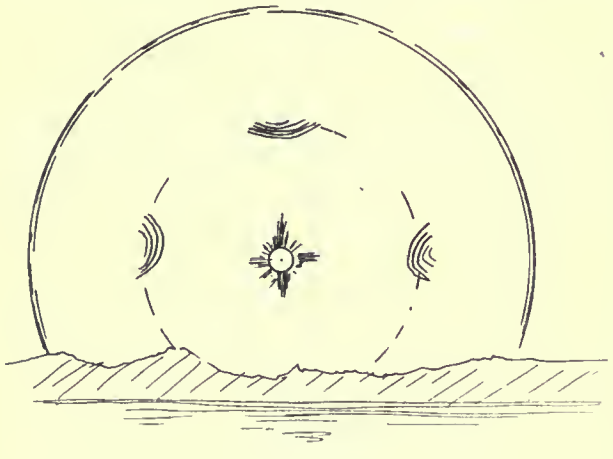
On January 10, 1908, at 10:30 A. M., the sky to the southward had the appearance shown in my sketch. There was a wide, and about three-fourths part complete, circle of light, showing the prismatic colors distinctly, although faintly. Inside there was another luminous circle, all but complete, with segments of brilliant illumination at three of the quadrants. This circle was not quite continuous, as the luminous circle could scarcely be said to join the bright segments, and, moreover, showed no prismatic colors.

The sky was perfectly clear, and the sunshine brilliant. Overhead there could be discerned, drifting slowly in the still air, minute needle-like crystals of ice, not snow. The temperature was 0°F. The luminosity of the quadrants was not of the intensity of the sun, and as the phenomenon vanished before noon, the intensity of the 'mock suns' was not as great as in the former observation (which occurred shortly after noon), when it was nearly as bright as the sun itself. You impute this peculiar occurrence, I believe, to the refraction of light on the ice-crystals passing in the upper currents of air.

Another phenomenon, which is witnessed during the first cold weather of the fall, pertains to the sunsets. On these occasions the rays of the setting sun are focussed into one perpendicular ray of light stretching almost to the meridian. The divergent fan-like rays of the sunsets are seen earlier in the season, and are of extreme beauty. For a short period, if the weather gets colder, and conditions are favorable, there is but one ray, bold, vertical, and rose-hued, that reminds one of nothing so much

as that biblical "pillar of fire by night"—a recorded phenomenon of other days.

The next phenomenon is not quite so pleasing. Its occurrence was on Christmas day, which comes 13 days later than ours, as Russia still adheres to the Gregorian calendar. In winter, across the broad flat steppes, blizzards, or *boorans* as they are called, are not uncommon—in fact, one is raging as I write. This *booran*, however, was what is known as a 'cold' one, a visitation of considerable dread on account of the danger to life if caught unprotected. The air was so thick with flying wind-driven particles of snow that objects even ten feet distant were all but invisible. On leaving the shelter of the house but a few feet away all objects were invisible—the house itself being indiscernible. Snow seemed to converge from all directions, blinding the sight and limiting the illuminated area to but a few feet in any direction. A gale of wind was blowing, with the thermometer at about 0°F or lower. Exposed to the fury of the wind, the face became chilled and in danger of freezing. To find a way was almost an impossibility. In fact, although I made the at-



Sun Phenomena.

tempt twice during the day, each time I deemed it prudent to beat a retreat, and found my own house then with difficulty, although the boarding-house, whither I essayed to go, was but a stone's throw distant. The danger consisted in the chance of missing one's mark and wandering on the open steppe, exposed to such weather it would not take long to kill all vitality. All sense of locality is as effectually blotted out as when lost in a November fog in London and, here one is not able even to "ask a policeman."

We have no local papers in these parts, and so news filters through slowly. We lost two men at this camp: one returned after being out all night, while the other is lost and his resting-place unknown, until the snow shall be compelled to give up its dead. At a neighboring camp two men were lost. Numbers of men, women, and children were badly frozen, some so badly that amputation was necessary. The number of sheep and cattle that perished must have been great.

To one that has not experienced such a wanton display of winter fury, it must seem incredible that it is actually unsafe to attempt even short journeys of a few hundred feet from the house, but such is undeniably the case. Happily these cold *boorans* are uncommon. Usually when the wind increases and the snow whirls over the steppe, the temperature rises to well above zero, but there are occasions when the thermometer refuses to rise. Such an unhappy record has the winter of 1907.

H. E. West.

Akmolinsk, Siberia, January 12.

Why Are Engineers Poor?

The Editor:

Sir—In the issue of March 14 your London correspondent refers to the fact that the financing, controlling, and business management of mining enterprises is almost entirely in the hands of laymen instead of mining engineers. The pertinent question is, why is this? Is the training of the engineer one that retards business acumen and aggressiveness? The engineer who would succeed must be a man of relentless initiative and organizing ability, conservative and calculating, with a world of experience. What element is lacking that we do not more often find him founding and heading enterprises in his own line of work? In nearly every one of the practical walks of life we see even the beginner determinedly setting his face and doggedly directing his steps toward being 'his own boss' and having a business of his own, but the mining engineer, with the best of opportunities along this line, allows someone else to skim the cream. Were the engineer's life one of indolence and ease, we could understand it, but it is one of severe mental and physical tasks from apprenticeship to retirement, one of nomadic existence, of life in undesirable and trying places, reputations easily lowered and positions of uncertain tenure—surely the reward should be great.

A prominent writer on business organization states the self-evident fact that a business undertaking has three essentials: the enterprise, the management, the capital; and he adds the observation that management is the greatest of these, since given a poor enterprise or little capital, or both, good management will pull it through or prevent an undue loss, while a good enterprise and plenty of capital is too often of no avail when harnessed to poor management, particularly in these days when competition is keen and promising prospects quickly snapped up. Can you expect to find this good management for a mining enterprise in a broker, or a druggist, or a clergyman—or in a mining engineer?

In every district we find villages deserted and properties closed down shortly after equipping or still containing good bodies of pay-ore, with only a few old-timers remaining to tell us "these hills have only been scratched." Had these properties been controlled, managed, and equipped by trained men, admitting many of the mines had but little merit, a large proportion of them would have run for years, supported thriving communities, and giving the stockholders a run for their money, sufficient at least to assure their interest in other properties, instead of making them decided opponents to mining investment. Logically, no man should be so well fitted to find the enterprise, to supply the management, and to attract capital by virtue of his knowledge of the

facts and opportunities, and his standing, as the trained man—the engineer. In practice he is too often unable—until well up the ladder of fame—to command capital because of the little opportunity to meet and form associations with men of means open for investments.

Some twelve months ago Mr. J. R. Finlay, in an article on 'Requirements of Modern Mining,' presented the necessity of the mining engineer being a good business man, and his frequent lack of business qualifications. I believe it can be truthfully said the mining engineer is not up to the standard of what should be expected of him in business ability. It is the business man of business attainments who is reaping the rewards in all lines of human effort. Someone will say the practice and technic of mining is sufficiently broad for any man, and very remunerative. Perhaps. But I notice every engineer looks forward to the time when his finances and business connections will allow him to settle down, unharassed by rough trips, arbitrary managers, and boards of directors, and discomforts of the mining camps. The salaried man, the wage earner, business man, and investor will all be benefited when the engineer makes his advent into organizing and managing enterprises.

The question at this moment is, what change must the engineer make in his training, and concept, and methods to enable him to come into his own.

H. W. MacFarren.

Blair, Nevada, March 18.

Concerning Superintendents.

The Editor:

Sir—In your issue of February 15 one of your correspondents in an article 'Concerning Superintendents' mentioned one who was—to say the least—very ignorant, and whose qualification for the position of superintendent was that he had taken a "ten dollar course in a correspondence school." Of course, I do not know what school, nor does it matter, but the slighting way in which the fact of the superintendent in question having taken a course in a correspondence school at all is mentioned, leads me to ask your correspondent if he means to condemn all such aids to self-education. Take a case like the following, for instance: Given a man who has been working underground for 30 years, and in camps ranging from the Sierra Nevada to Salt Lake, and from the British line on the north to the Mexican line on the south, during which time he has held every position from mucker to foreman, and given satisfaction to his employers, also that he is considered a good all-round miner and timberman, etc., capable of handling running ground as well as hard rock. This man wishes to rise to higher positions, but finds that his lack of technical knowledge is in his way. This he determines to overcome. He has others to support as well as himself, and so cannot spare the time to go to either Stanford or Berkeley, much as he would like it, and much as he realizes the importance of a university training. What then is he to do? He wishes to educate himself. Is he to refuse to avail himself of the help offered by such institutions as the International Correspondence School at Scranton, Pennsylvania. The cost of their course in mining engineering is nearer $150 than it is $10, that is, after the necessary outfits are bought. He has to sit up at night after work, and study, and he finds that the course is very thorough and that he has to get at least 75% on his examination papers, or they are not accepted. Does your correspondent mean your readers to infer that the fact that a man accepts the help that he can get in his studies should bar him from the ranks of the profession? I cannot think that the members of the profession are so illiberal and caste-bound that they will not admit to their ranks one who has educated himself, for the simple reason that he was not able to afford the luxury of a college education in his youth, and had to start in at the practical instead of the collegiate end. I will add that this is no imaginary case, but an actual fact. I will close by asking you if, after such a man has gained his diploma, can he expect recognition from the profession?

I well know the advantages of a college course over private tuition, even if the courses are identical, but under the above conditions what is a man to do? It seems to me that he would be foolish to refuse the aid offered.

C. R. G.

Sacramento, April 2.

[A man who makes the best of poor educational facilities deserves the respect of every professional man. Many men without the advantage of an academic training are better educated, and even more cultured, than university graduates. Whether an engineer got his training at a regular school of mines, a correspondence school, a night school, or by reading and observing on his own account, makes mighty little difference if he finally arrives, that is, if he becomes well trained and accurately informed. Some of these agencies for instruction are better than others, but the worst of them will make an intelligent earnest man more useful than the best of them when applied to a natural chump. Professional men are not illiberal; we welcome any man that can 'make good,' and if he has accomplished this under disadvantages, we honor him the more.—Editor.]

The production of electrolytic copper was attempted in 1879; in 1880 there was a small quantity made; up to 1891 the annual production was insignificant, but after that year the industry appears to have begun to get a good foothold. The first records obtainable start with 1897, and the following figures show the approximate output for each calendar year named: 1897, 250,000,000 lb.; 1898, 314,107,776; 1899, 386,410,356; 1900, 466,092,663; 1901, 477,954,569; 1902, 488,652,307; 1903, no record; 1904, no record; 1905, 760,000,000; 1906, 865,000,000 lb. These figures are interesting, as showing the rapid and steady development of this new branch of the copper industry; but this is not all, for in the refining of copper by the electrolytic method, a very large amount of the precious metals is recovered which under the old method was entirely lost.—D. Houston.

SKIPS AND CAGES.

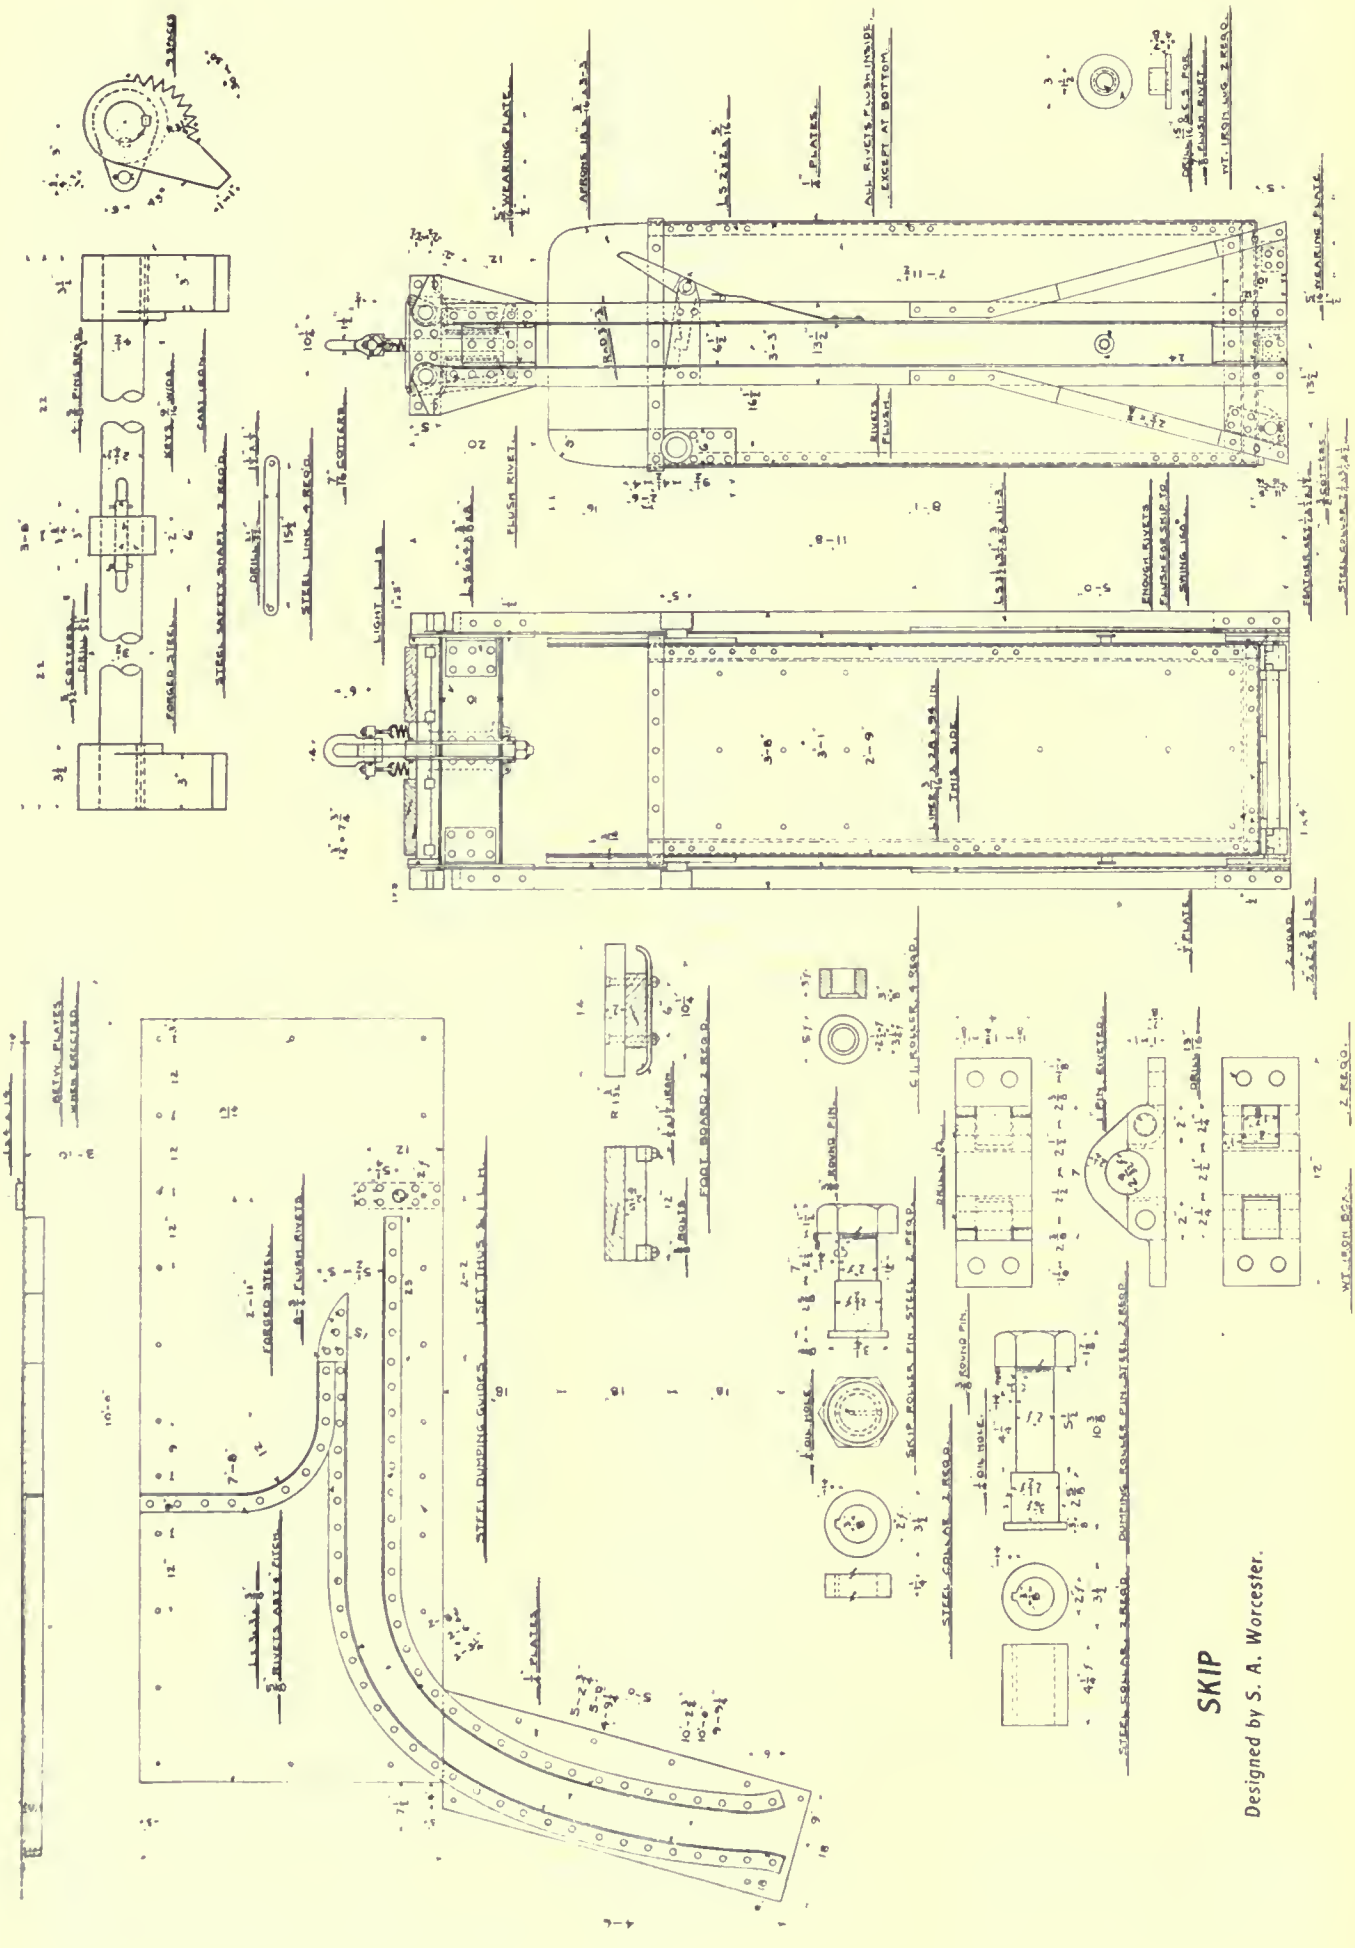
Written for the MINING AND SCIENTIFIC PRESS
By S. A. WORCESTER.

The prejudice, as I consider it, with which many mine managers regard the skip, as compared with the cage, as a device for hoisting ore economically, leads me to make a specific comparison of a number of the important features of the two devices, in practical operation. First, in the matter of loading, when an ore-car is dumped directly into the skip by hand, the time consumed is usually much less than is required to remove an empty car from a cage and replace it with a full one. In cases of large tonnage, such as to justify automatic apparatus for caging cars, a skip, with a special filler of proper construction, will load in less time than is possible with the cage. The filler that I have in mind is an ore-pocket having a capacity of exactly one skip-load; where bins are used for loading the skip, this filler is placed at the gate of the bin, and is filled from the bin while the skip is making a trip. This filler has a large gate or door, which is simply unlatched and swings wide open, so that not more than two seconds are required to fill the largest skip. There is no danger of over-filling, because the filler contains but one skip-load; and no time is lost by rock jamming in the door, because the filler is entirely emptied each time the skip is loaded. A variation of several inches, in some cases a foot or more, is allowable in the height of the skip when loading, but the cage must be landed carefully on chairs or landing dogs before cars can be changed. The repairs on cages and chairs, when operated to large capacity, are immensely greater than for skips doing similar work, and this is largely on account of the necessity of stopping on chairs. The loss of time at some mines on account of frequent damage to cages and chairs is something enormous. One of the most common accidents is caused by chairs being left projecting without the engineer's knowledge. On receiving the signal to lower, the engineer lowers the cage, perhaps at full speed, against the chairs, and the result is a bad wreck, and perhaps loss of life to an employee. The saving of time in unloading the skip is evident to anyone who observes and compares the working of the two devices.

For large capacity the skip should have at least four or five feet of head-room above the usual dumping height, so that it can be stopped anywhere within this range and dump itself quickly. By giving the dumping guides an easy curve, resembling the parabola, the dumping operation can be performed with great speed and safety. For rapid work the skip should be tilted to perhaps 60° from the horizontal, so that the ore will run out rapidly and no fine stuff will remain. With proper arrangements, the dumping operation should not require more than 10 seconds for the largest skip, counting all of the time that the skip is tilting, stopping, and returning to the vertical position. 'Caging' cars at the surface is nearly as slow as in the mine, and even the best automatic arrangement is slower than the skip, because the cage must be stopped twice, first above, then gently on, the landing chairs, and if double-decked or three-decked, a landing is necessary from each deck.

The cage, as ordinarily used, necessitates surface trammers for taking the ore to the ore-house, but the skip is easily made to dump into any one of a number of bins, by using suitable spouts or deflecting doors, thus eliminating tramming. While it is true that a skip requires a higher head-frame than a cage, the extra cost is soon repaid by the saving in labor and repairs and the increase in capacity. The capacity of a skip may be increased almost indefinitely by simply increasing its depth, and this without requiring any longer time for dumping, also without increasing the time of loading, when the filler is used. The skip herewith illustrated was designed for the No. 1 shaft of the Findley mine, at Cripple Creek, Colorado; it displaced the two-decked cage that had been used for some years. When using the cage, two trammers were employed on each shift to move the ore a distance of perhaps 30 ft. to the ore-house. They had separate tracks, one above the other, so that both decks were unloaded at the same time. The engineer, cager, and trammers were constantly busy, running the plant up to the limit of capacity. Accidents to cages and chairs were frequent, annoying, and expensive, with their accompanying delays. The skip now in operation hoists four mine-cars, or two cage-loads of rock. The trammers are dispensed with, the skip dumping into any one of four bins, as the ore is directed by deflecting doors. The head-frame was extended 32 ft., bringing the sheave-centres 92 ft. above the collar of the shaft. Soon after installing this arrangement it was found that the capacity of the plant had been more than doubled, so that while the mine was shipping exactly twice its previous tonnage, the hoist had frequent short periods of rest, and was not crowded to the limit of speed as before, when hoisting, and the operation of the plant generally was much smoother and freer from accidents and delays.

One objection frequently urged against the skip is that it is not so convenient as the cage for handling men, timbers, etc.; in this case the objection is overcome by making the skip-frame in the form of a cage, from which the box can easily be detached and hung completely out of the way, in a few moments. It can also be replaced with equal celerity and convenience, by one man; the removal of one spring-cotter from the pin-keeper enables the cager to draw back the pins that hold the hinged caps of the boxes. The skip, resting by its wrought-iron lugs in the skip-hangers, is then pushed easily back to the detached position, to remain until it is again needed. The shaft being small and not very straight, and the hoisting speed 1500 to 2000 ft. per min., the skip is made deeper than is usual, in order to obtain the required capacity. The latches absolutely prevent the skip-box from tipping out of position and encountering the shaft-timbers. The hinged box-cap before mentioned was suggested to me by observing that a cap used for a similar purpose at another mine once dropped to the bottom of a 1400-ft. shaft, into 75 ft. of water, and the skip was put out of commission until a new cap was made. I therefore avoid



SKIP

Designed by S. A. Worcester.

this danger by having loose no more important part than a spring cotter. This could be temporarily replaced by a nail or a piece of wire, if lost. At this mine the car is dumped directly into the skip. It will be noticed that the springs operating the safety-dogs are placed inside of the framing and thus protected from damage by the car when loading the skip.

The original cost of a plant for skip-hoisting, including an excavation for a pocket at each level, is much less than that of a cage equipment, including the necessary large number of cars and the excavation for double tracks at each level. One car only, for each trammer, is required where bins are used at the levels, and the excavation for bins is not over one-fourth of that required for double tracks for cars, for a given capacity. Where unbalanced hoisting is practised, the proportion of dead weight of cage and car or cars, or of skip, to the ore hoisted, is a matter of importance, as affecting the power consumption, as well as the speed and capacity of the hoist. The weight of the Findley skip, although heavily lined and substantial, is several hundred pounds less than that of the double-decked cage and two cars which it displaced, although it carries twice the ore-load. The objection that the skip is inconvenient for handling men and supplies, is overcome, in some cases, as, for instance, in a plant that I designed for a Telluride mine, by carrying a cage a short distance above the skip, so that the cage-floor aligns with the level when the skip is at its loading position. Where, as in this case, balanced hoisting is invariably used, the item of weight of cage adds nothing to the work of the hoist, except a little friction, and is not objectionable.

At some mines it is considered important to hoist each car of ore separately, accompanied by a trammer's tag, specifying the particular bin for which it is destined. In nearly all such cases it is perfectly feasible to use several skips in one frame, all dumping simultaneously, but each into its own particular spout, below which is placed a car. They can also be loaded at one setting, by using properly arranged spouts, thus avoiding re-setting, which would be necessary if the skips were loaded singly at the level. Little ingenuity is required to devise an arrangement that will handle the trammers' tags with greater safety than at present. It is also a simple matter to direct the ore to different bins by using deflectors, as at the Findley plant, or by using dumping guides at different heights in the head-frame, and so arranged that any set can be switched into or out of line, to dump the ore at different heights and send it in different directions. Mining operators are gradually awaking to the merits of the skip, which in its early forms was an old Cornish device, but even at this late date is not nearly so well known and generally used as it should be.

Cupellation losses are due to absorption and volatilization. The loss of gold and silver depends upon the temperature of cupellation, the amount of lead with which the gold and silver is cupelled, the physical condition of the cupel, and the nature and amount of the impurities present.

Freight Traffic.—Few people have any definite idea how fast railway freight actually moves. The layman's idea about the matter would probably be something like 20 miles an hour. But the truth is that there are not a few lines on which 20 miles is a good day's journey for railway freight to make. That is what James J. Hill reported as the average rate on his roads in hearings on the subject of car shortage, a year or more ago. Meanwhile there have been numerous complaints of lack of promptness in furnishing transportation facilities for livestock shipments in the Southwest. In connection with this inquiry the Interstate Commerce Commission collected definite information on the subject. The result of the inquiry is that the average distance reported for freight cars, for 14 roads west of the Mississippi, was 29 miles a day in 1906. The average in 1900 was 31 miles, or a reduction of 6.4% in six years. The figures below represent several of the leading transportation systems, and may be taken as fairly representative of conditions in their territory:

Roads.	1900	1906
Great Northern	28	28
Northern Pacific	28	31
Burlington	34	32
Missouri, Kansas & Texas	37	24
Rock Island	30	27
Southern Pacific	34	34
Missouri Pacific	20	17
Texas Pacific	38	27

Is it probable that these averages represent decreased efficiency of the freight service, such as President Mellen had reference to when he accounted for the backward trend of railway business by saying that labor had probably lost a quarter of its efficiency within the last half a dozen years? The explanation given by livestock shippers is that the railroads let their cars stand idle while waiting for additional cars in order to make two engines in so many trains do the work of three under earlier conditions. The result of this effort at economy has been to overload engines, increase breakdowns and accidents, and greatly reduce the promptitude of service. Numerous complaints have been presented of livestock shipments over long distances in the Southwest and West, which did not average more than from 4½ to 10 miles per day, thus increasing the expense of caring for the stock 100% and causing much loss of weight in the condition of livestock. Such figures as these certainly look as if somebody had lost the grip on railway transportation.—*Boston News Bureau.*

Tellurium is tenacious in its hold on gold and silver, and if a high-grade telluride ore be assayed, even by special method, the beads from cupellation will frequently contain tellurium. In the crucible assay the slags absorb gold, and owing to the presence of tellurium in the lead button, gold is absorbed by the cupel. A good flux for the ordinary silicious ores is made up as follows: potassium carbonate, 7 parts; sodium carbonate, 6; borax glass, 5.5; flour, 1; litharge, 30 parts. About 75 gm. of this flux is used with 0.5 assay ton of ore.

WELFARE OF LABORERS IN REDUCTION WORKS.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

No manager or superintendent of a reduction works has a right to think himself a superior being, to whom the working man is to bow down, but rather as a trustee responsible for the proper use of the human instruments under his charge. Like him, they have self-respect and feelings that are to be considered, and yet the things which he thinks a comfort and an advantage, may not appeal to them. He must therefore study their ways sympathetically, though critically, and put himself in their place. Thus he will increase their efficiency, add to the interest of the men in the work, and avoid strikes, to say nothing of the humanitarian aspect of the case. If his men have confidence in his ability, in his desire for their welfare, it will go far to bringing about economical results.

A reduction plant is essentially a manufacturing establishment where metals are extracted from ores, or where the crude metals are refined, hence the principles underlying the organization and management of factories, of which so much has of late been written, is applicable to reduction works also.

There are two considerations to be regarded, first the purely commercial, which is interested in the largest tonnage at the least cost, and which involves not only cheap operation but efficient machinery, apparatus, and furnaces; secondly, the combination of this with a provision for the moral and physical welfare of the men with the view to retaining them, and making them more efficient and more satisfied with their work. Not much has heretofore been done in the latter direction, but managers of such plants are having trouble in times of scarcity of labor (which are also prosperous times) in retaining their men. At other times labor may be cheap, but it is then possible to make it also more efficient.

As far as improved factory surroundings go, a beneficial effect can be exerted upon operatives who have been accustomed to a lower way of living where the surroundings are only those demanded by law, and have fostered objectionable habits, disregard of the value of property, contempt of authority, and opposition to the plans of the projectors of the improved order of management. As far as reduction works are concerned, they usually grow with the increase of the supply of ores, without increased provision for the welfare of the men. Conditions have been no more settled than those of mining, and the temporary aspects of surroundings such as one sees in the typical mining camp reflect the temporary aspect of such enterprises.

But this condition of affairs, with the evolution of more permanent conditions, can hardly be good business, and the amelioration of conditions has been taken up to a varying degree in plants, even of the same company. Thus, we find near the new Garfield plant of the American Smelting & Refining Co. a town with comfortable houses and well stocked stores, erected for the benefit of employees. The plans, when carried out, will make this settlement as desirable almost as that of the nearest city, 18 miles away. On the other hand, we find the surroundings of another plant of the same company so bad that only the most indifferent labor can be secured, and even that must be carefully nursed and catered to, at the expense of discipline. Where foreigners have been obtained for work about such plants, the company has sometimes furnished them quarters where they were herded by the hundred, and where their sanitary conditions, as well as their diet, have been of a nature to keep down their efficiency, their intelligence, and their comfort.

The companies permitting these conditions are not altogether to blame, since they do not in many cases know how bad conditions are, or again, they feel that the problem of amelioration is rather a hopeless one. Then again, the demand for good dividends makes them unwilling to invest money in improvements.

Still, the problem must be tackled. Labor-unions are making their demands for higher pay, and, in some degree, recognize and appreciate improved conditions. A reduction work can well afford to study conditions in order to make progress. For example, where foreign labor is employed, their food is not sufficiently nutritious, and their physical performance is low. If the company were to introduce soup kitchens, where soup, bread, and well cooked beans and meat could be procured at a low price (as cheaply as could be had at home), made palatable at the same time, we would find the men better nourished and more vigorous. This is well illustrated by Mexican labor in the Southwest. In Mexico we find the labor most inefficient; near the border within the United States the same laborers, because of better food, have become more efficient, and as we go northward the quality improves among the American-Mexican population.

As an example of what has been, and what can be undertaken, in this way, let us consider the work of Robert Owen at New Lanark, Scotland, in 1799 —over a century ago—but with bitter opposition on the part of the people he benefited. Large families had been crowded in wretched hovels, and the filth was beyond description. He at first provided each workman and his family with two rooms to live in, and then cleaned up the streets and encouraged cleanliness in the homes. Schools were unknown there; he started them. He provided a hospital, a sort of club-house for dancing, music, and entertainments, a kitchen and an eating-house, a wash-room properly equipped, a library, and a lecture-hall. Stores were at the same time opened, where superior goods were to be had at moderate prices. Finally, a ten-hour day was introduced, and child-labor largely reformed. In spite of the opposition of his partners to his plans, Owen's business succeeded amazingly, and paid increased dividends, so that he retired at the age of 58 a wealthy man.

Today we find a general disposition to recognize the normal obligation of the employer to the worker, and the feeling that it is good business to treat the employee decently. One can find manufacturing establishments where safe, comfortable, and even

attractive surroundings are given, as also facilities for recreation and for mental and moral development.

The most important consideration, from the point of view of the business man, who is becoming interested in the problem, is that it pays dividends in spite of the capital that must be used in providing these improvements. One factory employer, indeed, in summing up his experiences, says: "One of the most profitable investments that can be made in a manufacturing plant is to give the largest possible advantages in the way of conveniences and sanitary arrangements. Every kind of legitimate comfort and convenience that may be provided for operatives is a source of profit to the employer, although apart from the moral obligation to care for the health and comfort of the employee." Another employer, doing a large business, who had improved conditions and surroundings, being asked if it paid, said: "Three years ago we had a standing advertisement for help wanted in every paper in the country, and then could not get enough. Today there are upward of 100 applications on our waiting list. Last year, with 60 people less on our pay-roll, we did a business of $20,000 more than the year before."

Experience, as far as manufacturing establishments are concerned, goes to show that from the contentment, intelligence, and willingness on the part of employees, the employer himself gets a greater advantage in the way of economical output and increased profit. It must be admitted that there are many employers who yet manage their business with minimum consideration for their work-people, and who declare they have a sufficient supply of labor, but with them there is always more or less conflict with employees, and in times of prosperity, when they should be making their greatest profits, they are held back by a shortage of labor.

It is these principles, applicable to the factory, that may be used in the management of reduction works. Let us see then how they may be applied: In the first place, we have to decide who should give attention to these matters. A large concern might afford to have a man appointed as a welfare-manager, or a company having several plants could appoint one in an advisory capacity to visit and inspect the different plants. However, at any individual plant, ultimate control must be held by the superintendent, who is obliged, for greatest effectiveness, to keep in touch with his men. To make these improvements must then devolve upon him, or upon an assistant whose duties involve the responsibility for details, always under the supervision, with the approval, and in consultation with, the superintendent. This officer is the only proper one. For the business manager to step in and interpose his authority would lessen the contact of the superintendent with the men, where, for efficient technical control, he should know those who are to carry out his plans. Upon the assistant then will devolve this welfare work in addition to, and supplementing, technical duties to which he gives chief attention. The question might arise whether such a man, while good as a metallurgist, might not be successful in this work. It can be replied that it should be possible for him to learn; and again, since he is in order of promotion to the superintendent's place, he must learn those duties which the superintendent successfully supervises and controls. The chief must also realize the importance of this work, and not set it aside as secondary to output and operation. Dissatisfaction and strikes are to be headed off by precaution, rather than fought after they come. Shutting down a plant does not stop general expenses, and certainly does stop profits. It reflects upon the company, and upon the superintendent, whether justly or unjustly, and the reputation of the latter depends, not only on technical execution, but also on the management and efficiency of his men. Hence he must not only attend to their welfare, but he must go among, and get in touch with them.

Such work for the welfare of the men naturally divides itself in two: those for his comfort during working hours, and those during his hours of rest and recreation. The first division is closely connected with operation, and is chiefly watched by those in charge, who see that they are properly used; and the second group needs, in addition to the cost of erection and maintenance, the co-operation of the men benefited.

Referring to the first group, I shall first take up the consideration of protection from accidents incidental to the use of machinery. Platform-elevators should be regulated by automatic stops, since they are operated by the common laborer; self-closing gates also should be supplied at the landings. Gearing must be covered, and belts and pulleys, where they are liable to be touched, guarded by a safety-rail or cover. Belts should be kept in good repair as regards lacing. Holes in floors, such as those for stairs and hatches, are to be railed in, and temporary holes covered promptly when not in use. Shaft ends, liable to catch clothing, should be guarded and safety-collars used. In general, the machinery should be so protected that the careless and the ignorant are prevented from getting hurt. Signs, printed in a language understood by the men, are to be posted, and they both give warning and protect the company against legal consequences.

Lighting the plant, not only adds to the efficiency of the men, but to their comfort. Additional windows can often be put in, and white-washing the interior surfaces is a great help. Paint also adds to durability, as well as lighting, and both it and white-wash can be of a nature to lessen the chances of fire. Ventilation is a thing that is often sadly neglected, even in recently designed plants. This is particularly true of works treating sulphide ores. Sulphur fumes escape into the building, when by improved hood and liberal exit-flues much of the trouble can be obviated. Even after the fumes escape, their discomfort can be greatly lessened by liberal ventilation. In situations like that of a crane-operator it should be possible to give a special supply of fresh air.

Heating is often neglected about a metallurgical plant, and operatives are exposed to the weather, so that they suffer more than they should, and use

part of their time in trying to keep warm instead of working. Such men work in excessively warm places, and in cooling off are exposed to drafts and damp, with great risk to themselves. Indeed, heating and ventilation go hand in hand. In summer, windows are needed for ventilation, in winter they are closed to retain the heat. Then it is that special provision is to be made for ventilation without losing much heat. In front of furnaces the fumes from the tap-holes can often be collected by hoods, and these carried by a common pipe to a suction-fan. Where there is much dust, the bag-house has been introduced, primarily for the saving of valuable material, but incidentally greatly adding to the comfort of the men. Where ore is crushed dry, the dust is often thick, annoying, and obstructs the sight. Machines that produce it should be cased in and connected to a central fan-system, and thus the building freed from all the dust practicable. It costs to keep a place clean, and yet it pays in many ways to do so. A slovenly establishment is a reflection upon its superintendent, and causes slovenly work or waste. A reduction works in disorder, with tools lying around or forgotten in corners, is wasteful, because these things are practically lost. Where dust and filth are allowed there is discomfort to many of the men, and those the best ones. Smooth walls (easily painted), concrete floors, and well-laid common floors are more easily swept, more easily traversed by wheelbarrows. Wooden floors should be double, for convenience of repair, and are then also tight.

Cleanliness in the person of the workman is to be desired, and yet in many metallurgical operations it is hard, in fact, impossible, to keep so. Nevertheless, a struggle should be made to minimize such discomfort. For the bag-houses above alluded to, helmets carrying a supply of fresh air are to be had which enable men to go into such places without risk of life. If dirty work cannot be avoided, at least proper means for washing after work should be put in. In so many places one sees buckets standing round, which each workman takes time, during his shift, to fill with water, often obtained at much inconvenience and loss of time to the company. An improvement on buckets is a long trough supplied with hot and cold water. Even this is not satisfactory, as men object to washing in a common water, and individual wash-stands, such as those seen in railroad stations, are to be preferred. The men furnish their own soap and towels. A simple installation consists of ordinary enameled wash-basins, so arranged that they may be tipped into a drain-trough below. The bowls and their surroundings should be kept in order, and in repair, and be cleaned up constantly by the janitor or his assistants. The men should have a ventilated wooden or metal locker to put their clothes in, instead of hanging them up anywhere, at the risk of being injured or stolen. These lockers are often heated below the bottom by a steam-pipe running underneath, thus drying the clothing that may have become damp.

Many metallurgical operations are dusty and hot, causing sweat. Men working at them need a bath at the end of the shift. For this the shower bath, having both an upward and a downward jet, is the most satisfactory. The bather stands on a wooden grating and the dirty water entirely escapes. Probably a fixed supply at a comfortable temperature would be most satisfactory, otherwise water should be left running. This can be furnished from a flushing tank, as in a closet. Above anything else, proper attention should be given to the matter of suitable closets for the men. Great attention should be given to building them so that they can be easily cleaned: they should be semi-private, that is, divided by partitions, and watched to prevent misuse. The simplest accommodations are good enough, provided there is cleanliness and proper sanitation, as well as a degree of privacy. The place should be so that it can be washed out with a hose.

Men who feed furnaces have periods of rest and of labor. So long as they keep the furnace supplied they can take rest as they please. For them some provision should be made, as comfortable benches in a comfortable place, especially in cold weather. These places may well be where they can still have their work under supervision. One of the most unsatisfactory, and at the same time difficult, problems is that in relation to the noonday lunch of the working-men, and especially that of the inside men about reduction works. A man must give attention to his duties, which may call for his total time during the noon hour, and must find time to eat his lunch as he can. In works reducing lead ores this is especially detrimental. Food carelessly eaten with dirty hands transfers lead-bearing dust to his digestive organs and results in lead colic. The man cannot go far from his work, and indeed in a large plant this will take time and effort. Let us consider what has been done at other industrial establishments:

At some establishments places have been provided for the officers and foremen for a noon-day meal, when such facilities were lacking near-by. These places are fitted up by the company and run without profit, the finances being in charge of one of the office force in addition to his regular duties. This, however, does not take care of the working-man, who at noon takes advantage of the nearest saloon, adding beer to his regular food. The beer, after its temporary stimulus is gone, makes a man apathetic, and diminishes his capacity for work during the rest of the day. The alternative is generally sitting upon some pile of material, or on a bench, and hastily eating his meal with dirty hands. Such conditions detract from a man's self-respect, and he is disposed to resent it, even if he says nothing. If something better than this is to be provided, a room, or in a large plant, several of them, can be furnished with plain tables and chairs. These places must be kept clean and swept out, or else they will become disused; that is, unless they excel the old method, the workmen will not use them.

A favorite plan is an arrangement to sell good hot coffee, bread, or soup at a low price. Two cents for a cup of coffee with cream and sugar will pay its cost. This is taken with their lunch brought from home. The price of the food sold him, as well as its quality, cuts quite a figure to the working-man, and

since his attendance is purely voluntary he must be catered to. Another plan that works well is the delivery of 10-cent lunches by some outside concern, which at the same time is willing to sell smaller quantities as needed by the workmen, such as coffee, milk, or bread. This is delivered to the men by distributing wagons, which appear about the works promptly before the noon hour. The 'cafeteria' scheme is another way, and is excellent when men get trained to the method. Each man helps himself, under proper control and check, and takes a chair with a broad arm on which his food rests. It lessens the cost of attendance and expedites the work at the rush hour, and has been found to work well. That the men specify what they have taken or what they owe, is an additional training, putting them on their honor. The watching of the men is unobtrusive, and a cheat will be found out after a little while: in fact, the service should conduce to good-will on both sides.

The question of water-supply is important, especially for men working in the heat. The usual way is to supply barrels, from which the water can be dipped out by a cup. A freely running tap from which the water can be drank without a cup is better, but it should be cool. Again, water is stored in barrels, to which ice is added, and the water drawn by a faucet. For men having hot jobs, water alone does not seem to be so satisfactory as that where oatmeal is used, half-a-pint to a barrel of water. This also diminishes the desire for beer. The barrel should be cleaned out, and fresh oatmeal added daily, it being placed in the water in a muslin bag.

Regarding the attention to be given to facilities for rest or recreation, much can be done. The plant may be in some out-of-the-way place, and the company may have to operate its own boarding-houses. To give satisfaction here the food should be in abundant supply (but not wasted), should be digestible and palatable, that is, well cooked and well served, and, while avoiding needless variety, should consider the former habits of the men. The statement often made by mine managers, that good food is the greatest attraction and one of the best means of holding the men, is quite as true for the employees of reduction works. It should be the duty of the superintendent to look into this, to take an occasional meal with his men, and thus find out how they are looked after. Provision has been made by some companies, and especially by mining companies, for their married employees by furnishing them houses, commonly built in long rows and strictly on the same plan. Variety in the style, and in the size of these houses, should be introduced, to suit the families that occupy them, and more attention should be given to make the surroundings attractive. Here again comes in the work of the welfare manager, who is an expert in such matters, and who can see that such plans are carried out in an efficient way, and then turn them over to the charge of the superintendent.

The indirect influence of cyanidation in stimulating mining exploration has exceeded its direct service to the industry.

Pocket Mining.

All the rich spots are not in Nevada. In California there have been many fortunes dug out of a space no larger than a living-room, and from some of the larger 'pockets' some splendid masses of gold-quartz have been extracted. Thus, in July and August, 1881, the Rainbow mine near Allegheny, in Sierra county, yielded $95,482, besides a lump of ore weighing only 200 lb. but estimated to contain $21,180. All of this money, that is, $116,622.88—to be exact—came from 1962 lb. or less than one ton of ore. The lump was sent to Johnson & Matthey, the London assayers, and they returned over $23,000. But pockets are like a donkey's galop, short and sweet. H. H. Noble worked this mine for 22 years after that 'bunch of ore' was taken out of it, but without 'seeing a color,' until 1905, when some more rich stuff was found. In February, 1906, a shipment of bullion worth $11,600 was made, and the mine is now doing well. A few days ago another pocket was struck. The bonanza mined in 1881 was 130 ft. long and 180 ft. deep. All of it was milled. Outside of the specimen stuff, most of the vein was hungry-looking quartz, that assayed from $1 to $30 per ton. It was discovered when driving a bedrock tunnel under a gravel deposit. The 'pocket' was simply a rich spot on the foot-wall of a poor quartz vein, 4 ft. wide. There was no cross-vein or fault at the enrichment. On being driven out by an excessive flow of water, the owners drove a 3000-ft. adit to cut the vein 500 ft. under the former workings. Where the vein was finally intersected it was merely a barren stringer. A raise was started and this eventually reached the upper workings, where $5000 was extracted from ore left in the old stopes. Just below this level the vein was shattered, and if the owners had sunk a few feet deeper (before being driven out by the water) they would never have made the long adit.

The Tightner mine is adjacent. H. L. Johnson extracted $65,000 from one ton of ore taken from this mine. Subsequently, in 1906, he bonded it to Senator John P. Jones and his brother. They were to pay $100,000 in cash and $100,000 in deferred payments. Being disappointed, they never completed the transaction. Johnson went to work and took out $200,000 almost immediately. Such is mining in a pockety gold vein.

Lyons is an important centre for the electro-chemical industries, about 100,000 hp. being used. For the production of aluminum 35,000 hp. are used, for that of calcium carbide 25,000, and for chlorates 15,000 hp. The power employed for electric steel furnaces and the manufacture of ferro-alloys is 22,000 hp., while 3000 hp. are used for other chemical manufactures. More water-power is being developed and a marked increase in these industries is expected.

Of the many oxidizing reagents used in cyanidation, only a few have been found to have any practical utility.

EARTH MOVEMENTS AT BUTTE, MONTANA.

Written for the MINING AND SCIENTIFIC PRESS
By R. H. CHAPMAN.

*In 1904 precise level lines were run at Butte, Montana, and some 18 bench marks located. This work was done to establish reference points for drawing lines whereby to detect the changes in levels due to the caving of the extensive underground workings.

A line was run about four miles north and south across the undermined area and benches established at the ends, one in the flat south of all workings and one in the granite on Walkerville ridge, well to the north of extensive workings at that date. An east and west line extended approximately two miles from Meaderville to a point near the Big Butte. In addition, a circuit of about 10 miles was run northeastward to Elk Park pass, and a tie made to a bench mark of the work of 1896. To this earlier work, and also that of 1899, I shall refer later.

In 1906 the Coast and Geodetic Survey brought a line of precise levels from the southwest (Pocatello, Idaho), and tied to several of the benches of 1904 (9 in all).

Beginning at a point near the Butte Reduction Works, in the flat south of the hill on which most of the mines are situated, and running northward, the following differences appear:

		Ft.	
1.	Butte Reduction Works B. M	0.000	¼ mile
2.	Webster School	0.017	1 mile
3.	Colorado St. School	0.051	
4.	Owsley Block	0.436	
5.	Courthouse	0.737	1.5 mile
6.	Government Building	0.888	

This line shows an increasing subsidence in the benches as they are nearer the extensive underground workings.

A second line shows a similar condition:

		Ft.
1.	Butte Reduction Works	0.000
2.	South Butte B. M	0.051
3.	Braund House	0.130
4.	Florence Hotel	0.791
5.	Government Building	0.888

The above figures give a subsidence for the two years (1904-06):

Owsley Block.....0.218 ft. per annum
Courthouse.....0.368 " " "
Government Building.....0.444 " " "

This shows a differential of:

0.150 ft. between Owsley Block and C. H.
0.076 " " C. H. and Government Building.
0.226 " " Owsley Block and Government Bdg.

The comparison between the work of 1896 and 1899 and that of 1904 cannot be relied upon with the confidence given the later figures, but it is found that between the years 1896 and 1904 the Courthouse had sunk 0.895 ft. with reference to the Owsley Block, which must itself have gone down to some extent during that time. This change is at the rate of 0.112 ft. per year. The total subsidence at the Courthouse from 1896 to 1906 is undoubtedly as much as 1.632 ft., which is at the rate of 0.163 ft. per year.

*Published by permission of the Director, U. S. Geological Survey.

The long circuit of 1904 to the eastward was run from Butte across the line of the great structural fault of the Rocky Mountains, and a reference bench mark set on the east side of this fault-line. By combining the earlier work (1896-99), and comparing it with the results of 1906, some interesting figures appear:

Between Owsley Block and Elk Park Pass B. M.
In 1896 ..... +663.161
In 1904 ..... +663.839

an interval of 8 years, with a change of +0.678 ft., most of which is accounted for by the sinking of the Owsley Block, but by indirect comparison between the Owsley Block and a bench mark to the west (combining work of 1896-99, and applying a subsidence correction for the Owsley Block), it is found that the Owsley Block has changed —0.551, and the difference between this and the +0.678 obtained from Elk Park B. M. gives a difference of 0.127, more than a tenth of a foot for possible movement along the fault-plane in 8 years. This figure is of doubtful value.

During the work of 1906, in conversation with Mr. H. V. Winchell, he said that he hoped that by frequent re-running of the level lines we would be able to determine if movement is continuous along local fault-planes and the continental fault of the range, and to measure any such movement found. The figures given cannot be accepted as final, but they show changes of such magnitude as to renew interest in the work already done and to offer a basis for additional work for more complete comparisons. It is hoped that the levels will be repeated at short intervals in the future.

Comparative tests of shoes and dies of different kinds of steel have been made at Lucknow, N. S. W., ranging over a year's milling of 10,000 tons. Cast-iron and chrome steel were compared, with the following results:

	Life, weeks.	Duty, tons.	Wear per ton milled, lb.	Wear per shoe, lb.	Cost per ton milled, d.
Cast-iron	8	79.95	1.201	96	2.730
Chrome steel	32	319.78	0.419	134	1.816

The above tests were made with steel imported from Germany, and subsequent tests were made with English chrome steel castings, and in every instance the English steel proved superior in duration and cost, the margin being small in the former particular but over 10% in the latter. In the above tests the value of the discarded shanks is credited to the cast-iron shoes, but not to the chrome steel scrap, which was useless for the local foundry. Chrome steel when first put on the market for milling fell into disfavor locally owing to the inferior grade of castings supplied.

The success of an industry is not furthered by the maintenance of unscientific secrecy, but rests rather on the broadcast dissemination, among progressive nations, of accomplished truths, on the reciprocation of enlightenment, on the exchange of valuable knowledge—in short, on the scientific spirit of enterprise aided by international technical co-operation.

FLOTATION PROCESSES AT BROKEN HILL.

Written for the MINING AND SCIENTIFIC PRESS
By an Occasional Contributor.

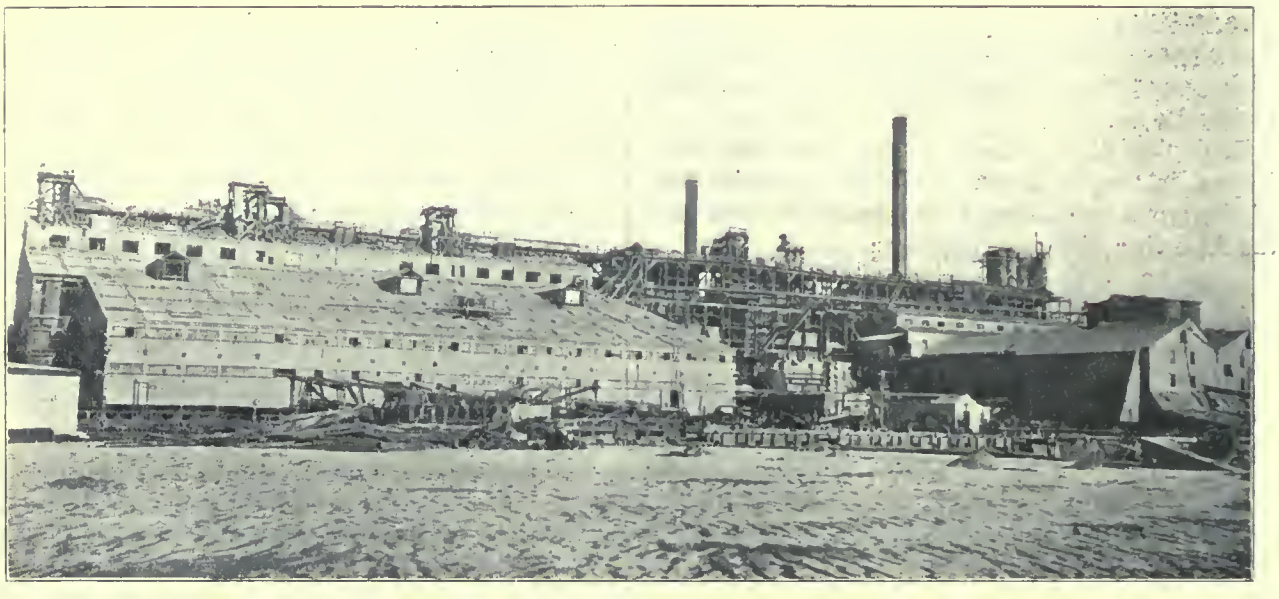
Minerals Separation Ltd.—This company's processes have their greatest development on the Central mine of the Sulphide Corporation. There are four plants here, with a total capacity of 2000 tons per day. One of these plants treats 500 tons per day of pure slime, with an extraction of 87%, producing a concentrate that assays 36% zinc and 30% lead. The plant is now closed down because of the low price of lead. The other three plants treat 500 tons per day each of tailing and slime mixed as they come from the lead concentrators, and, with an extraction of 85%, produce a concentrate assaying 47% zinc and 10% lead. This process (erroneously called the Cattermole) was tried by the Zinc Corporation and thrown out as a failure.

Potter Process.—Since the consolidation of the Delprat and Potter interests, the Delprat process has become a thing of the past. The Broken Hill Proprietary is using the Potter process only. The tailing from the Wilfley tables, mixed with re-ground material from the dumps, is washed clear of slime, and is fed to Potter pans 9 by 9 ft. at the top, and 16 ft. deep, where it comes in contact with strong acid solution. The extraction of the zinc is said to be 90%, in the form of a concentrate assaying 40% zinc. The plant treats 1200 tons per day at present, but an enlargement of capacity is being considered. There is a persistent rumor at Broken Hill that the Proprietary is using two tons of oil per day in this process.

De Bavay Process.—This is in use on the Broken Hill North mine. The tailing from the lead-mill is washed clear of slime and sized to eliminate all material over 60-mesh size. This washed and screened material is delivered to an A. Z. Clark agitator, which takes 15 tons of material to the charge. After agitation with water an acid wash is added. This acid wash consists of a weak solution of sulphurous acid made on the ground, to which is added 5 to 10 lb. per ton of tailing of strong sulphuric acid. After agitation is complete, the tailing is transferred to a pressure-vat, where it is agitated under an air-pressure of 60 lb. per sq. in., and an oil emulsion is added to aid subsequent flotation. From this vat the aerated and oiled pulp is forced by pressure to the head of the mill, where it is run into storage-hoppers. From these hoppers it is fed in a thin stream onto inclined tables, where the oiled and aerated mineral floats off and the gangue sinks. These particulars are well guarded, but the fact that an oil is used to aid flotation in this process is admitted by those in charge of the plant.

Elmore Vacuum Process.—After the failure of the Minerals Separation process, the Zinc Corporation adopted the Elmore process, and it is expected that the new plant will start in March. The preliminary testing has been very favorable, and indicates that the Elmore machines will have a capacity of 25 tons each per day. There are 16 machines being installed, thus giving a capacity of 400 tons per day. It is proposed in this plant to re-treat the concentrate by roasting off the oil, and then concentrating on Wilfley tables to recover a portion of the lead. The total recovery and grade of concentrate produced in this plant will be much the same as by the Mineral Separation processes on the Central mine. The Pinnacles Elmore plant has been closed down by reason, according to the manager, of high costs and low extraction. He says they will put up a new wet-table mill and abandon the Elmore process.

Gillies Process.—This process on the Block 10 mine has been abandoned because of high costs and low extraction. There was some discussion of adopting the Minerals Separation process in this plant, but the plant was not adapted to the scheme and it was not carried out.



Concentrating Mill of the Broken Hill Proprietary Company.

Talcose or clayey ores when crushed for cyaniding make a great deal of slime which is exceedingly difficult to leach, and hence require treatment as a slime, adding greatly to the cost of extraction.

A METHOD OF MINING.

Written for the MINING AND SCIENTIFIC PRESS
By C. EVERARD ARNOLD.

In working the Union claim on the Smuggler vein during the early 'eighties, much bonanza gold and silver ore was mined and packed over the mountains by mule-trains to Sheridan Junction, being taken thence by rail to a smelter at Alamosa. As the ore was mined the stopes were filled with the vein-matter that was not sufficiently rich for shipment and smelting, that is, all material worth less than $100 per ton. Lately these old stopes have been leased from the Smuggler-Union Company by Messrs. Lindsley, Townsend, & Livermore, a firm of mining engineers and mine lessees, who have devised and applied a scheme whereby the stope-filling is mined profitably.

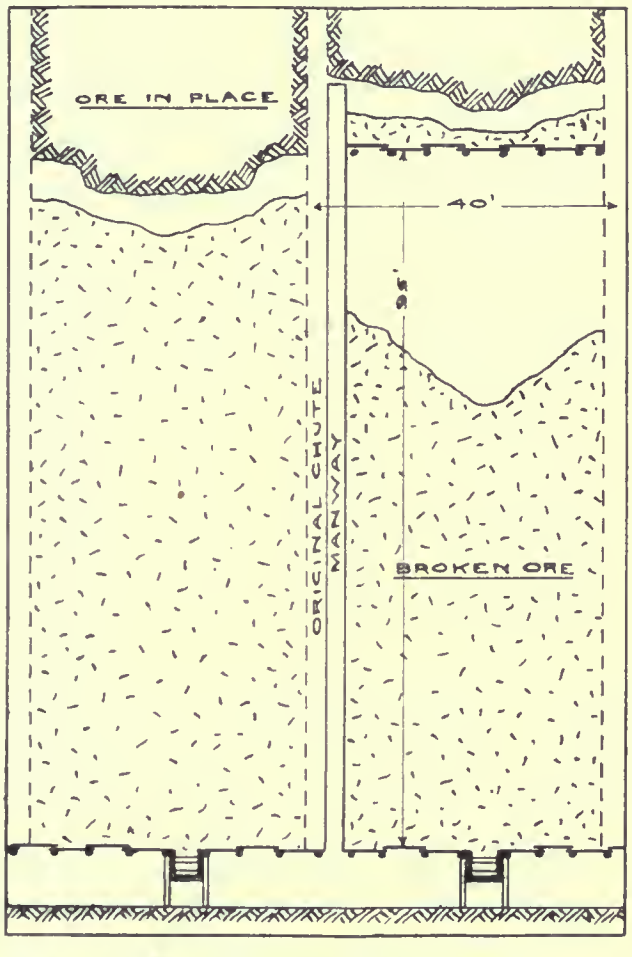
This pseudo-vein, as we may call the filled stope, strikes N 25° W, and dips 75° toward the west, having an average width of about 4½ ft. In appearance it is a gray soft agglomerated mass of quartz and country rock (andesitic breccia) fragments vary-

Smuggler, Colorado.

ing in weight from an ounce to 100 lb., these boulders being cemented together by means of the more finely shattered and clayey material of the original vein. Not least among the factors that enable cheap mining is the extent to which this ground will hold itself in place. Although soft enough to be mined wholly with a pick, a fairly sound stope-back can be maintained, provided it is always kept within reach of the miners.

In deciding on the scheme of mining to be used, the lessees fortunately had behind them the experience of having worked some of the old stopes farther north on the same vein by means of sorting underground and re-filling with the waste. Although, as pointed out above, the ore supports itself well, yet it was found that in mining thus the back of the stope would progress faster than would the level of the filling, so that as soon as control of the back was lost, not only were the lives of the miners endangered, but also in catching up the stope again considerable dead-work was necessary. This difficulty could have been overcome by using half-sets in conjunction with the filling, but the tenor of the ore, and the excessive cost of timber delivered in the mine, prohibited such an arrangement.

In the scheme now in use, sorting underground has been done away with. The original level, after twenty years abandonment, had caved to such an extent that practically a new level, timbered with 14-in. stulls, had to be driven, using the old timber whenever possible, and that was seldom. Chute-mouths were built 40 ft. apart, as it was found that the original chutes (indicated on the diagram by dotted lines) had been placed at intervals of 40 ft., and as they had rotted and crushed throughout their length and, moreover, were exceedingly difficult to remove, they were left in place, thus dividing the ground into 40-ft. blocks, in each of which stoping is now being carried on independently. Man-ways are maintained, beside alternate original chutes, and



Method of Removing Slope-Filling.

the stopes are connected, for purposes of communication and ventilation, by chopping holes through the crushed chute-timber.

In working these sections, stoping is begun at both ends and the two breasts carried toward each other to the centre, while enough rock is drawn from the stope to leave working space for the miners. After the two breasts have come together, a fresh bench of ground is stoped, and the process repeated until there is a depth of 90 or 100 ft. of broken rock resting on the lagging. Next a row of stulls is put in and lagged over, stoping then being continued as before, while the ore on the floor beneath is drawn out. Enough ore is left on the lagging to prevent falling rocks from breaking out any drift-stulls. When ore is needed from the floor above, or the stope becomes too crowded, the lagging is chopped out of a false set placed in the middle of the floor, and the ore runs through the emptied stope below. No lining or cribbing is used for the chutes, and no

shovelers are required until the stope is almost empty. As soon as the material is shoveled off a floor, the lagging is removed and used above, although these floors are not always removed, because it is found advisable to keep a reserve of broken ore in case stoping is delayed.

The ore is trammed by hand for several hundred feet through a cross-cut to an ore-house and dumped onto grizzlies (with 7/8-in. spaces) the undersize going directly to the ore-bins, while the oversize falls onto sorting tables. The waste is then picked out, the amount rejected constituting about 33% of the material mined. From the bins the ore is loaded directly into the buckets of an aerial tram, reaching the mill (1½ miles distant) in three stages, crushing taking place at the end of the second stage. Horse-tramming was tried between the stopes and the ore-house, but several costly wrecks occurred on account of a bad track, which cannot be advantageously altered during the severe winter weather, when the floor of the cross-cut is a mass of solid ice.

At the present time 235 tons of ore are sent to the mill every 24 hours. Disregarding the item of amortization and realization, the operating costs amount to $3.32 per ton of ore milled, this amount being distributed as follows:

	Per ton milled.
Stoping and timbering	$1.40
Underground tramming	0.28
Sorting	0.19
Surface tramming and crushing	0.70
Milling	0.75
Total	$3.32

Wages average $3.50 per shift. Taking into account the number of all the men employed at underground work and ore-sorting, the tonnage milled per man per day amounts to 3 tons; while under the system of sorting underground, referred to previously, this figure amounted to 1.7 tons.

Combustion, under conditions as found in the mine, of candles and lanterns will continue in air containing 3% carbon dioxide, if handled with great care, but they give very little light. Experiments made in an air-tight box provided with means for burning charcoal, while circulating the enclosed air and sampling it, showed that candles and lanterns were extinguished at once when from 3 to 3.5% of the oxygen was converted into carbon dioxide, and were extinguished by a very slight jar at more than 2%. An acetylene lamp continued to burn in still air containing a higher percentage of carbon dioxide than a candle would stand, but the flame became yellow and finally almost blue. At this stage it separated from the burner like a cap and was blown out by the slightest draft. Charcoal fires, even when a considerable mass was strongly glowing, ceased to glow when the carbon dioxide rose to about 7 per cent.

The price of aluminum was reduced to 22 c. per lb. on Jan. 1, 1908, by the international aluminum syndicate, which is composed of the principal producers in Germany, France, England, and America.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

A miner injured by timber falling back upon him by reason of a defective chute was held to have assumed the ordinary risks of the business, but not any extraordinary risks, unless it appeared that he was aware of such at the time of his employment, or that, upon learning of their existence, he continued in the employment after the lapse of a reasonable time for the defects to be remedied or removed.

Leary *v.* Anaconda Co., (Mont.) 92 Pac. 477, Nov., '07.

Where a miner was injured by falling timbers caused by a defective chute, an instruction that it was the mine-owner's duty to provide the miner with a reasonably safe and sufficient rope and chute to hoist timbers from a mine, to make a reasonable inspection thereof, to keep the same reasonably safe, and to use ordinary care in so doing, was objectionable as placing too great a burden upon the mine-owner, and the correct rule was held to be that the mine-owner was only required to exercise ordinary care to furnish reasonably safe appliances and to keep them in a reasonably safe condition.

Leary *v.* Anaconda Co., (Mont.) 92 Pac. 477, Nov., '07.

The business of an employee in a mine was to work in a blacksmith shop on one side of a tram railway. The place where the drinking-water was kept was on the opposite side of such railway, and it was customary for the employees to go to such place for water. Such employee in crossing the tram railway while returning from getting a drink of water was injured by reason of negligence attributable to the mine-owner in operating cars upon such tram railway. The court held that at the time of his injury such employee was entitled to the same immunity from injury from negligence as when actually at work in the shop.

Woodward Iron Co. *v.* Curl, (Ala.) 44 South. 969, Nov., '07.

A miner of eight years' experience, and who had been head man in drill-work in a mine for over a year, was guilty of such contributory negligence as to prevent recovery for injuries from an explosion of dynamite where it appeared that he had knowledge that the bar with which he pushed and tamped the dynamite into its place was defective, and where he determined for himself the depth of the holes and how to put in the sticks of dynamite and used his own judgment as to the force necessary to get such sticks in place, and where he admitted that he was pushing hard on the dynamite at the time of the explosion, and he knew that pushing too hard would explode it.

Thornburry *v.* Old Judge Co., (Mo.) 105 Southwest. 659, Dec., '07.

No particular method of marking the boundaries is required under the statute providing that a mining location "must be distinctly marked on the ground so that its boundaries can be readily traced," and what is a sufficient marking may depend on the topography of the ground. In such case, it is a question of fact whether or not the lines are so marked that they can be readily traced by a person making a reasonable effort to do so.

Charlton *v.* Kelly, (Alaska) 156 Federal 433, Oct., '07.

Where a person, after filing adverse claim, sued in the State Court to quiet his title, under State laws, such suit was not affected by the statutes of the United States which provide that where an adverse claim is filed, publication of notice of an application for a patent, all proceedings, except the publication of notice and the making and filing of the evidence, shall be stayed until the controversy shall have been decided by a court of competent jurisdiction, or the adverse claim waived.

Bernard *v.* Parmelee, (Cal.) 92 Pac. 658, Oct., '07.

GEOLOGY.

By James F. Kemp.

*In all parts of the world, as we follow down through the successive layers of the fossiliferous strata, we find an ancient nucleus of crystalline rocks, gneisses, schists, marbles, serpentines, and minor varieties. The geologists who are now in middle life were quite universally taught by their instructors of twenty-five or more years ago, that the old strata were all sedimentary in origin, although now thoroughly crystallized and of vast thickness. Not a few believed that they represented materials which had been worked over many times by the ocean and the other forces of erosion. The prevailing banded or parallel arrangement of the constituent minerals was the proof of their sedimentary character. But today when we look back we find that we have greatly advanced from these views and that we hold conceptions which much more satisfactorily fit the observations. We know that the banded arrangement of the minerals, light and dark, is not necessarily evidence of sedimentation, but that it may have been produced by a pressure so great and irresistible as to cause the crystalline rocks to flow like viscous masses, and to drag and shear the minerals into long parallel leaf-like relations, suggesting indeed the bedding of sediments, but radically different from it.

While these conclusions have seemed inevitable to the observers in the field, yet at least one inquiring mind could not rest content until the processes had been artificially reproduced in the laboratory. By a brilliant piece of work and with the aid of elaborate and expensive apparatus, F. D. Adams, of McGill University, has first tightly encircled cylinders of Carrara marble in jackets of tough sheet iron. He has then submitted them to slowly but irresistibly increasing pressure. As the strain passed their limit of crushing resistance, and while they were so tightly encased in the tough, but yielding jacket, that they could not crack, they have passed from cylinders an inch in height to discs of half this altitude and of correspondingly increased diameter. Yet they have never lost their cohesion but have moulded themselves like so much wax. When removed from the jackets the discs are as solid and homogeneous as were the original cylinders.

These experiments are very recent, but Professor Adams is now continuing them upon other rocks such as granite; and instead of dry compression, now admits steam or heated water to the cylinder and seeks to reproduce in these respects the conditions of deep burial and metamorphism. In so far as the results have yet gone, they are a striking corroboration of the conclusions reached by observers in the field, among whom Professor Adams also occupies a most honorable place.

But we are likewise assured that banded or foliated structures may be original with igneous rocks. We have learned that molten masses in cooling and crystallizing sometimes separate into contrasted layers of light and dark colored minerals which may be brought by the conditions of eruptive flow into parallel relations suggestive of sedimentation but different from it. The field worker of today upon the oldest rocks therefore constantly keeps in mind the question, am I dealing with igneous or with sedimentary types? And the general result has been to prove in the areas of the oldest rocks a series of sediments indeed, but of greatly restricted amount and thickness as compared with earlier views, and to constantly abstract large fractional parts and prove them to be eruptive rocks, which have been forced through and between the ancient sediments. Vast masses of granite and similar types are now known, sometimes attaining dimensions of tens or even hundreds of square miles, which are later than the old limestones and sandstones, and which were regarded by our predecessors as one with them. On the whole the sedimentary antecedents of the fossiliferous strata have become much restricted in amount, and the time which they were once believed to represent has suffered diminution in a corresponding ratio.

At the close of the eighteenth century geologists well understood in a general way that the constituent strata of the earth could be classified in a systematic series of which some were older and some later. Soon after the middle of the last century the larger subdivisions were recognized, which we now call periods, and substantially the same names that we use today were given them. Geologists knew that before the appearance of life, or in the Archean times, there were the Laurentian and Huronian periods. During the era of ancient types of life, or the Paleozoic, there were six periods, respectively, the Cambrian, Lower and Upper Silurian, Devonian, Carboniferous, and Permian. During the middle era, or Mesozoic, there were three, Triassic, Jurassic, and Cretaceous. During the latest era, at whose close we ourselves are living, there were two, the Tertiary and Quaternary. These eleven periods since the advent of life were each distinguished by its own types of organisms, now fossilized, and each was believed to be quite definitely and sharply outlined. If a European or an American geologist were to visit Asia or Africa, it was expected that he would find the evidence of the same times, and of periods that were contemporaneous and equivalent with those already known to him at home. This conception lasted until well beyond the student days of geologists now living. But as time went by the point of view changed and one finds today a much modified attitude regarding this, the very foundation of the stratigraphic or historical portion of the subject. The old view was as if we should endeavor to co-ordinate all human history with the chronology of the Romans; whereas in China or India events were progressing without regard to Rome and or equal importance to the human race broadly considered. Multitudes of men, so great as to dwarf the numbers of the Mediterranean peoples by comparison, lived, moved, and had their being in Asia, quite unaware that a Roman had ever existed. So in geology, we have learned that while there is a general similarity of conditions over the world at

*Abstract, by permission, from a lecture delivered on November 13, 1907, by the professor of geology in Columbia University and published in the *School of Mines Quarterly* of January, 1908. Copyright Columbia University Press.

any one time, yet the conditions have not been uniform and that each locality must be viewed by itself. We have all come to realize that so far from establishing contemporaneous life, identical fossils in separated localities indicate a wide difference of dates. The studies of the paleontologist lead to conclusions similar to those of the zoologist, that groups of animals or plants migrate from centres, spread abroad along belts of favorable conditions, sometimes driving out earlier inhabitants, and certainly for a time mingling with them until in the end they established colonies remote from their starting point. These migrations require long stretches of time, and radically change our old conceptions. The same species on opposite sides of the world means, therefore, not the same time for both, but a long interval between. Indeed, while in one locality organisms of a later type may be flourishing, elsewhere animals of earlier and more primitive characteristics may still be in the full tide of their activities. Just as today in Australia we have a fauna which is a survival of genera long since extinct in other parts of the world, so in the past, whose records have come down to us, the same contrasts have prevailed. What is Quaternary or Recent in one place, may be Mesozoic simultaneously in another.

You will see at once how much more complex is the history of the globe, when interpreted in the light of the higher criticism which places the observer face to face with actual conditions, and how changed is necessarily the attitude of the geologist of today regarding these fundamentals when compared with that of his predecessors, and even with the views of his own earlier instructors. Turning to the future outlook, shall we anticipate the passing away of our established chronology? Shall we cease to speak of a Cambrian or a Carboniferous period as world-wide in its application and of fairly sharp definition? Shall we reduce ourselves to local sections each with names of geographical derivation and suited to a limited area, only running comparisons in a very general way? Some geologists have been impressed with this as the inevitable development. But others, while appreciating the limitations placed upon the old divisions and the mistaken views which followed their precise and universal application, yet see in them when discreetly and wisely employed, the statement of a great truth. Realizing the indefiniteness of the boundaries, they yet cling to the underlying and vastly useful general application and will long continue to use the time-honored terms. The two periods of the Archean era, the six of the Paleozoic, the three of the Mesozoic, and the two of the Cenozoic in not too sharp application are certain to be retained for many years to come, but the tests of their identity must be more complex and must be applied with a more comprehensive grasp of the situation.

As regards the appearance and development of life upon the earth the two most interesting questions for the world at large, relate to its beginning and to its later stages. They concern on the one side the forms which the oldest living creatures assumed, and on the other the advent of man himself. We cannot contemplate these questions without having our thinking influenced by the evolutionary doctrines. The first remains of life in the Cambrian strata consist of hard parts such as the shells of mollusks, which were calcareous when the animals were alive and which retain in large degree their original composition. Only resistant and enduring materials of this sort could survive through long periods of time. They indicate highly organized creatures, and are generally believed to have been preceded by ancestors of simpler types. For the remains of these ancestors, geologists have searched the older strata with the care and persistence which the importance of the question demands, since to push the evidence of life back of the Cambrian is to win one of the great prizes in geological science. But hitherto the results have been most meagre. They are limited to a few indefinite tracks or questionable impressions.

Opinion, therefore, has swung around to the conclusion that the earliest organisms were marine and that they were soft-bodied animals which on death left no trace in the sediments of their time. Along two lines of attack there is a most interesting corroboration. R. A. Daly, now in Boston, has been led by detailed studies in the extended series of Cambrian and Pre-Cambrian strata along the national boundary between British Columbia and the northwestern States, to the conclusion that the Pre-Cambrian sea was devoid of dissolved salts of lime, and that, by reactions incident to the decay of soft-bodied animals upon its bottom it was robbed of such little lime as it might otherwise have had. For a number of reasons too complicated and detailed to present here, there is good ground for believing that not until the opening of the Cambrian was sufficient lime available in the sea water to encourage the growth of those hard calcareous parts which yield the fossil remains.

Along another line of attack very interesting conclusions have been reached. A. C. Lane, the State Geologist of Michigan, has sought to solve the problem of the composition of the oceanic waters at various periods in the earth's history by a study of the deep artesian supplies which we gain from boreholes reaching older and older beds. From the samples of course must be eliminated contributions from higher horizons of matter not contained in the waters at the time of entombment. When all precautions are exercised we discover in the end that the oldest waters are relatively dilute when compared with the sea of today and that they have but seven parts in the thousand as contrasted with the modern thirty-five. Common salt was the most abundant then as now. A very interesting connection of these researches with the problems of early life is furnished by a line of investigation pursued by R. Quinton, of the College of France. In all but the simplest organisms there is a so-called vital fluid which is the basis of the circulatory system. If, for instance, we eliminate from the blood of vertebrates or other animals the red and white corpuscles and the products of organic waste and then analyze the remaining fluid we find a weak solution of common salt in water

varying slightly in the different types, but something like seven or eight parts in a thousand. This is believed by Mr. Quinton to represent the ancient sea water in which the ancestors of all modern organisms lived and from which some forms emerged in the past. Employed as a vital medium of circulation it became enclosed in those organisms which developed the interior sack having only communication with the outer world by osmosis, and its composition having been preserved, it recalls the early ocean, in which their ancestors originally lived. It is at least a striking coincidence that the composition of the vital medium is just about the composition of the sea as indicated by Dr. Lane for the early Cambrian or Pre-Cambrian times. If, as seems not unreasonable nor improbable, this composition, attained in the absence of salts of lime, was particularly favorable to organic life, then the Pre-Cambrian sea may have swarmed with soft-bodied organisms. And if, with increasing land areas, more lime poured in from their drainage and the composition of the sea changed, then some animals took to the land, others developed hard parts and left the fossil remains. But in the vital medium of their circulating systems they maintained a solution corresponding to the composition of the sea water which had proved most favorable to their nourishment in the previous marine period of existence. These suggestions are at least ingenious and turn our thoughts into new and promising channels which are worthy of careful exploration.

Toward the opposite extreme in the geological record of life upon the earth lies the problem of man's appearance, a question which links geology with anthropology. It is only upon its geological aspects that I purpose to touch, and solely of two of its phases do I desire to speak. That the general attitude of educated people toward this problem has become more tolerant in fifty years is now well realized. One may refer to the evolutionary descent and antiquity of man without, as happened in the case of the famous Calaveras skull, thereby cutting short the life of a State geological survey. We were formerly too much inclined to mix up souls and bones.

It is now 48 years since Darwin's 'Origin of Species' was first published and 36 since his 'Descent of Man' appeared. The last-named work squarely propounded and defended an evolutionary development from ancestors among the primates. In anatomical relations to living types there was a profound gap between man and the highest apes, most marked to the general comprehension in the sizes and shapes of the skull and brain cavity. Interest became focused upon the hoped-for discovery in some hitherto unexplored part of the globe either of the still surviving 'missing link' or else of fossil remains intermediate in type.

In the three or four decades which have elapsed since Darwin's books started investigations, no discovery of living man-like creatures of additional significance in these respects has been made; nor do we believe that such exist in the deep recesses of any unknown jungle. But in one notable instance the search for fossil remains has been more successful. On the banks of the Bengawan river, in Java, there are Pliocene or late Tertiary beds that for several years prior to 1895 were explored by Eugene Dubois, a military surgeon attached to one of the Dutch regiments. Dr. Dubois unearthed a partial skeleton of a man-like creature whose leg-bones showed that he walked erect and whose skull was intermediate between those of the highest apes and man. The volume of the brain cavity is two-thirds that of the average man, and the outline of the skull is not very different from some of the lowest types already known among prehistoric remains. Suppose that we assume a critical attitude and insist that if man existed in these times, we question whether this specimen is a fair representative. We may consider it abnormal and below the average of his day. Nevertheless the presumption is strong that it is normal, since abnormal ones are the rare exceptions. Granted this, many have believed that the remains point to a separate line of descent from that of the apes, and that if we consider the fossil as indicating the ancestors of men, then the latter have come down a branch or phylum distinct from the line of the primates.

As to the presence of man in relation to the great ice sheet of the Glacial epoch, it seems now fairly well established that in Europe he was existant in the later stages. In America the evidence is less strong and abundant, and while such as we have has been subjected to much destructive, and, it would seem at times, strongly prejudiced criticism, yet there is some rather good ground for inferring that on this side of the Atlantic as well as in Europe, primitive man was living in its closing stages. The results, however, of patient and comprehensive investigation have operated to show the great complexity of the Ice Age. Its boulders and sands are of widely different and contrasted dates. We may not rashly assume its contemporary character in separated parts of the country. Man's presence in its closing stages but reveals the long duration which went before while yet portions of North America were in the grip of extreme cold. The best we have done is to show that presumably in the later stages man was existant.

The labors of the Swiss, French, and German geologists in the wonderfully crumpled and faulted strata of the Alps and the no less fruitful observations of the Americans in the Appalachians have established the several kinds of folds and faults, the great structural features of the sedimentary rocks.

In the regions of extinct and dissected volcanoes, moreover, and in the localities of deep-seated eruptive rocks, the records of many patient workers have taught us of the forms and features of the igneous group. The excavations of the miner have revealed both sedimentary and eruptive rocks with an accuracy and minuteness of detail not afforded in any other way. To the general conceptions now firmly established in this branch of the subject we are not likely to add much that is new or important in kind, but within the last few years we have seen them greatly change in degree. We have long known, for

example, that excessive contraction of the crust first doubles strata together, then pushes the compressed fold over on its side, and finally forces the crumpled mass along above the beds lying beyond the folded area, leaving older ones stranded upon later. In the southern Appalachians, the overthrusts have carried the beds as much as five miles from their starting points and subsequent erosion has destroyed any visible connection. With some such distances as these we have long been familiar.

But recently the European geologists have worked out cases in the Alps where the shove has displaced the beds as much as fifty miles from their old positions. It has therefore been necessary to enlarge our conceptions by a factor of five or ten. The discoveries are new and the distances involved are so great that some time will be required in which to readjust our old-time sense of proportions, but we all realize that in these greatly compressed areas the movement was propagated along a fault plane or a series of fault planes of flat inclination which began well down in the earth's crust and which probably once continued beyond their present lines of emergence. When, however, we seek some satisfactory cause or explanation of these phenomena, both smaller and greater, we are as yet not entirely successful. The contradictory riddle of every great mountain system still confronts us. For example, we know that from New York to Alabama that portion of the Appalachians which we ordinarily call the Alleghenies consists of sands, muds, shell-beds, and coral reefs, the latter two often comminuted to slimes. In the case of the sands and the muds, the materials must have been worn by the waves from older lands, presumably to the eastward. They must have been laid down in shallow waters, layer on layer, until they became thirty or forty thousand feet thick. It is a difficult question to decide what caused the great trough to sink so gently that sedimentation nearly kept pace with subsidence throughout the long Paleozoic era. Why does the earth wrinkle downward in some localities for long periods of time and then, more remarkable still, why does it suddenly change its course and wrinkle upward, bringing the one time bottom of the sea into wave-like ridges which follow one another like so many great billows, petrified in mid-course as they roll in upon a shore. These evidences of past disturbances even more significantly than the earthquake shock of today lead on irresistibly downward to the interior of the earth and to the problem of its physical condition, one of the most interesting with which we have to deal and one regarding which opinions have passed through many changes in late years.

When the geologists who are today in middle life were students, the earth was widely believed to consist of a crust, perhaps 50 miles thick, hardened upon cooling, and surrounding a highly heated molten core which fed the volcanoes, which admitted of adjustments, and which was the still hot representative of the old incandescent nebula from which all had been derived according to the nebular hypothesis. In my own student days, the attacks of the mathematicians upon this view were beginning to be felt by the geologists. The important consideration of the rigidity of the earth, resisting deformation as it does while rapidly rotating, the lack of internal tides and similar arguments were leading to the view that a vast liquid interior was an impossibility. The effects of the pressure produced by the weight of the outer portion which rests upon the inner core and its effect in raising the fusing point to temperatures impossible of attainment were also gradually realized. A compromise view became widely prevalent. It involved the outer crust which we knew from experience was solid, evidently to a depth measured in miles; an inner layer of fused material, intervening before the pressure became too great; and then a solid core. From the fused layer came the lava of the volcanoes. Its adjustments made the ups and downs of the mountainous regions possible and its shrinkage and that of its crust from loss of heat, furnished the contractile strains which primarily caused the folds and faults. Joseph Le Conte, for so many years the greatly beloved instructor in the University of California, was a stout defender of this conception.

But the mathematicians returned to the attack and on the principles of sound mechanics maintained with force that nothing but an essentially solid and resistant globe would survive the evident strains to which it is subject. We must believe, they have told us, that from surface to centre the earth behaves with no less rigidity than would a sphere of steel. Gradually geologists have come around to this view, but have modified it by a further conception which must be coupled with it in order to account in any satisfactory way for the evident phenomena of the mountains on the one side and the volcanoes on the other. The earth is solid, we admit; it is highly heated, certainly to very great depths; but all matter, however brittle under the conditions prevailing at the surface, becomes appreciably plastic when confined on all sides and subjected to pressures beyond its crushing resistance. Under these circumstances, rocks will flow as viscous media while losing in no respect their cohesion. In the deep-seated metamorphic rocks we see these evidences of flow, and that the flowage is possible, we positively know from the experiments of Professor Adams.

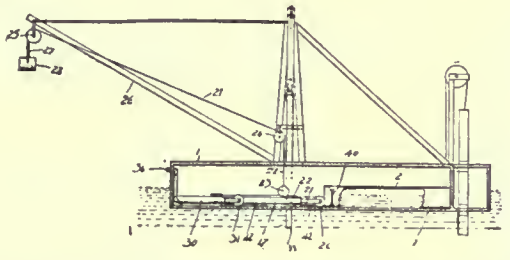
We may, therefore, regard the interior as essentially solid, yet moving with a slow viscous flow in any direction of less pressure. It undoubtedly is highly heated, yet it is not a molten liquid as formerly regarded. If, however, during a viscous flow toward a point of less strain the interior rises toward the surface, it is subject to less and less pressure, and inevitably in time reaches conditions under which the rocks must fuse. The vapors and gases held in all deep-seated strata are freed, and the once solid rock becomes the molten lava with which we are familiar in volcanic eruptions. Volcanoes mark, therefore, at least in their inception, restricted areas in the upper world of such low or eased pressure that toward them the deep-seated rocks pass until they can flash into a molten and even explosive condition.

(To be Continued.)

MINING AND METALLURGICAL PATENTS.

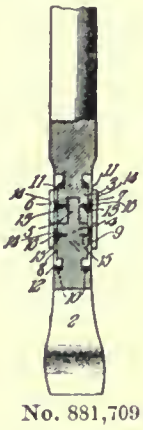
Specially Reported for the MINING AND SCIENTIFIC PRESS.

HOISTING APPARATUS FOR DREDGERS AND THE LIKE.—No. 881,838. Robert M. Wilson, San Francisco, California.

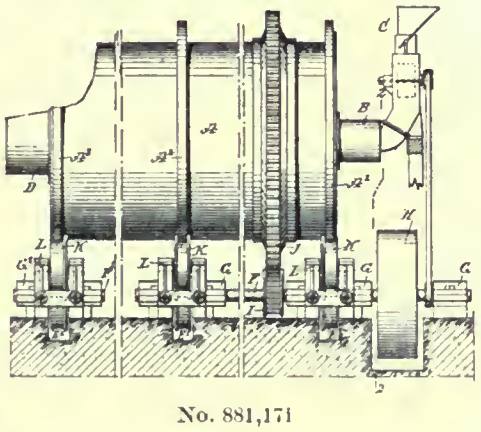


In an apparatus of the character described, the combination with mechanism for applying power, of a cylinder, a plunger therein, an operative connection therefrom to said mechanism, a receiver for pressure fluid, a connection therefrom to said cylinder, and means for forcing compressed air and a liquid into said receiver, substantially as described.

DRILL-CHUCK.—No. 881,709. Daniel J. O'Leary, Green Bay, Wisconsin.



No. 881,709



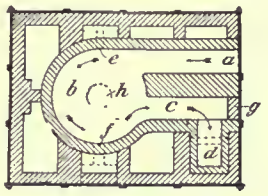
No. 881,171

A drill point connection for deep well drills comprising a drill rod having at its end an axial screw socket and diametrically opposed longitudinal grooves on each side thereof terminating in end recesses entering the body of the drill rod, a drill point having a screw stem adapted to the screw socket and the drill rod, and also having diametrically opposed longitudinal grooves terminating at one end in recesses, the grooves in the drill rod and drill point being located to match when the drill point is screwed into the drill rod, links having heads at each end projecting at right angles to the length of the links, and adapted to be seated in the grooves and recesses on opposite sides of the joint between the drill rod and point, and means for holding the links in their seats.

ROTATING DRUM.—No. 881,171. Richard F. Abbe, Hoboken, New Jersey.

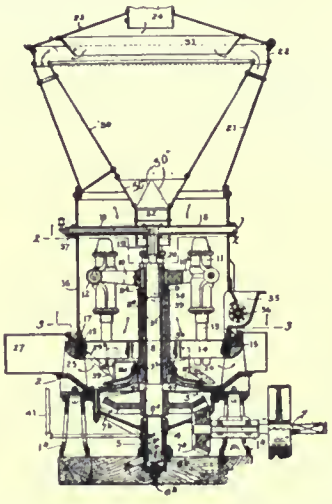
A device of the character described comprising a drum having external annular bearings, one located approximately at the middle of the drum and the others located at or near the ends of the drum, a gear wheel fixed on the said drum, adjacent to one of the end bearings, a driven shaft extending beneath one end of the drum and located in a vertical plane passing through the axis of the drum, supporting wheels mounted on said shaft and in frictional engagement respectively with the annular bearing at one end of the drum and the middle bearing, a pinion secured to said shaft between the said supporting wheels and in mesh with the gear wheel on the drum, a second shaft extending beneath the other end of said drum and in axial alignment with the said driven shaft, a supporting wheel loosely mounted on said second shaft and in engagement with the bearing at said end of the drum, guide rollers peripherally engaging the said bearings of the drum and located on opposite sides of the said supporting wheels.

REVERBERATORY FURNACE.—No. 881,110. Frank Cotton, Hornsby, New South Wales, Australia.



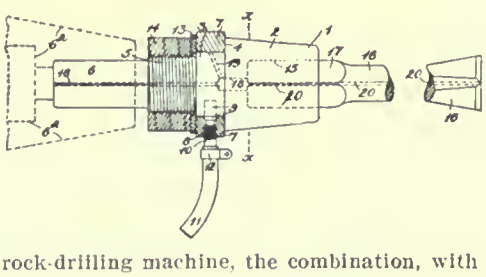
A reverbatory furnace comprising inner and outer walls separated by a filling of sand, a circular furnace chamber having a concaved floor and domed roof, an intake conduit arranged tangentially to the circumference of said chamber, the length of said intake conduit being approximately equal to the diameter of the furnace, and an outlet conduit parallel to and in the same horizontal plane as said intake conduit but located non-tangentially with respect to the circumference of the furnace chamber.

METHOD OF WORKING GAS FURNACES.—No. 881,724. Paul Schmidt and Adolphe Desgraz, Hanover, Germany.



A method of maintaining a body of molten material within a furnace at a uniform temperature throughout which consists in subjecting the material to the action of a heating flame which spreads in an even manner entirely over the material by introducing into the furnace a mixture of combustible gas and air, the latter being in excess of the former, and further introducing into the furnace a mixture of combustible gas and air, the former being in excess of the latter, said excess of air of the first mixture causing the excess of gas of the second mixture to be burned in the form of a long flame which evenly spreads entirely over the material.

WATER-SUPPLYING ATTACHMENT FOR ROCK-DRILLS.—No. 881,579. Henry Heilman and Lewis C. Bayles, Johannesburg, Transvaal.



In a rock-drilling machine, the combination, with a drill, of a detachable make-up piece positioned at the front end of the drill and supported and rotated thereby and constructed at the forward end with a hole of non-circular transverse section, a bit constructed with a portion of corresponding non-circular transverse section loosely positioned in the hole in the make-up piece and supported and rotated thereby and constructed with a longitudinal hole communicating with the hole in the make-up piece and leading to the cutting end, a swivel mounted on the make-up piece, and means for conducting water to the swivel.

THE GREAT ZUNI DAM.

The Zuni dam was completed during the month of January, 1908. The dam proper is 90 ft. high, 450 ft. long, 410 ft. wide at base, and 30 ft. wide at top. It is a combination rock and earth fill—the rock laid up dry 140 ft. at base, 10 ft. at top. The dirt was put in by the hydraulic process, and is 270 ft. at base, and 20 ft. at top. The slope was covered with a foot of gravel, on which was placed 18 inches of rip-rap set on edge, and on top of this was placed another foot of gravel. The water is drawn through a concrete tunnel 450 ft. long, which connects with a concrete gate tower 60 ft. high inside the reservoir. The reservoir when full will cover 640 acres, at an average depth of 35 ft. A spillway 100 ft. wide provides for the discharge of flood waters. The labor was done by Indians, superintended by a few white men. The dam was built by the Indian Bureau, for the benefit of the Indians of the Pueblo of Zuni. The water is to be used for irrigation purposes. The drilling of the rock for blasting was done by the use of Wood drills, supplied by the Wood Drill Works, of Patterson, New Jersey. These machines were operated by Navajo Indians, as shown in the accompanying photograph.

EGYPTIAN EXCAVATION.

From the Arthur Koppel Co. we have received an interesting note concerning the part their equipment played in the important explorations made in Egypt under the auspices of the Stanford Archæological Expedition. A view of part of the excavation work near the base of one of the Pyramids is shown; this gives an idea of the nature of the operations and the character of the labor employed.

By the use of Koppel portable track circular lines of rail were laid where excavations were being made. By this arrangement it was possible to tram the empty cars to the different loading stations and convey the loaded material to the dump without blocking the different lines. As the excavations were enlarged it was also easy to shift and adjust the track without serious interruption to the car service. The standard Koppel V double side dump-cars of 2-ton capacity were used for the transportation of the material. It was necessary that they be light-running when fully loaded, as the tramming was done by the natives. With this equipment rapid and efficient work was accomplished, and the adaptability of this equipment for widely different requirements was demonstrated.

COMMERCIAL PARAGRAPHS.

Atkins, Kroll & Co. of this city carry a stock of fine fireclay, silica, and magnesite firebricks, and are able to supply shapes, boiler tile, reverberatory furnace floor tile and assay furnace tile.

The Hendryx Electric Cyanide Co., Denver, Colo., has recently donated to the State School of Mines, Golden, Colo., a combination cyanide agitator and agitator for copper ores, to be used at the school for testing and experimental work for the students.

The Koch Mfg. Co. has just completed and shipped two 18-in. steel lined dredging pumps, each of which weighs over 30,000 lb. These special pumps are to be driven by two 500-hp. motors, and were designed to be used in deepening ship channels at Tacoma, Washington.

The Denver Fire Clay Co., of Denver, has recently started the glass-blowing department and is now prepared to do all kinds of special repair work, and will also make thermometers, hydrometers, etc., and do scientific and technical glass-work. This department has been closed down for some time past, and they have recently secured an expert from Scotland who has had wide experience in this specialty.

H. C. Holthoff has accepted an appointment from the Allis-Chalmers company as manager of the new office which is being established in Mexico City. H. C. Holthoff's office will be fully equipped to answer inquiries from prospective buyers of all classes and to furnish literature and quote prices on all lines of Allis-Chalmers machinery, including not only mining, crushing, and cement making machinery, but also steam-engines, steam-turbines, gas-engines, hydraulic turbines, electrical machinery, saw-mill and flour-mill equipments, pumps and pumping machinery, transmitting machinery.

CATALOGUES RECEIVED.

The Link-Belt Co. has issued its chain catalague for 1908.

The Keystone Driller Co. has issued Catalogue No. 6, describing Downie Deep Well Pumps.

The Schutte & Koerting Co. has issued catalogue No. 2, Section R, describing Koerting water-jet eductors for mines and tunnels.

The Clark Dredge Mfg. Co., of Chicago, has published an attractive folder describing in detail its hydraulic gold dredge. The pamphlet is well printed and illustrated.

PUBLICATIONS RECEIVED.

United States Treasury Department. Document No. 2493: 'Annual Report of the Director of the Mint for the Fiscal Year Ended June 30, 1907.'

The Department of Mines of Tasmania has issued the following bulletins: 'No. 1. The Mangana Goldfield.' 'No. 2. The Mathinna Goldfield,' and a report on 'The Progress of the Mineral Industry of Tasmania,' by W. H. Twelvetrees, Government Geologist.

Editorial.

A MEETING for organization of the Mining and Metallurgical Association of America will be held at the Engineers' Club, on West Fortieth Street, New York City, on Monday, April 20. The number of charter members enrolled is 106.

LONDON has a Lawson of its own and of similar character to the Boston mountebank, whose alarums and excursions into foul finance have prostituted the pages of the daily press. The spoofer in England is named Victor and in this way he differs from Thomas.

IT IS interesting at this time to note that the silicious ore of the Centennial-Eureka mine, at Tintic, Utah, is sent to the Mammoth smelter, in Shasta county, California. We look forward to a time when the smelting industry of California will be so developed as to stimulate the mining industry of the entire region west of the Rocky Mountains.

POSTAL RATES have a tendency to improve by diminution, and every increase of facility in this regard is of direct benefit to humanity at large. To business and to industry the postal lines of communication are as nerves to stimulate profitable energy. Many of our readers may not be aware that since October 1, 1907, the rate on letters to foreign countries has been 5 cents for the first ounce, or fraction thereof, and 3 cents for each additional ounce or fraction of an ounce.

THE DISMISSAL of the Federal suit against Mr. John A. Porter, of Denver, in connection with the acquisition of coal lands near Durango is of more than personal interest, for it is known that Mr. Porter was anxious not to evade trial but to undergo examination with a view to clearing his name of an unwarranted charge. In these days of careless aspersion of character and widespread corruption, it is a pleasure to record the fact that a man of honorable reputation was neither guilty of a charge of wrong nor unwilling to face the accusation.

MATTERS pertaining to the proposed Mining Bureau at Washington are progressing. The Senate has made an appropriation, to the Secretary of the Interior, of $190,000 for investigation of mine accidents and explosions. This appropriation is available either to the Geological Survey or the Bureau of Mining Technology, as circumstances may warrant. The money is subject to application at the discretion of the Secretary of the Interior. Senate bill No. 4783, for a Bureau of Mining Technology,

has been under discussion by a sub-committee of the House Committee on Mines and Mining. Mr. W. P. Englebright, of California, who is chairman of this sub-committee, has done splendid work, and the hearings have elicited valuable evidence. The strongest advocates have been the spokesmen for the coal operators and the miners' unions. This measure has been almost the only thing they have agreed upon this year, and both parties have sent strong delegations to Washington to work for the bill on the ground that what was most needed at present was scientific investigation rather than compilations of so-called "practical information" by legislative commissions. If the House takes the responsibility of passing this bill, the Senate is likely to agree. All interested parties, in the Survey and out of it, are working in apparent harmony, and the question of statistics has been shelved for the present. Whatever the result, the public discussion of the problems created by the tremendous growth of the mining industry is sure to be beneficial, by awakening the interest of the public and stimulating the intelligence of the legislators.

ON the editorial page of *The Call*, a San Francisco newspaper, we read that the output of the gold mines of the Mysore, in India, is increasing, although our readers are well aware that the production from the Kolar goldfield—the only one in Mysore—has been steadily declining since 1905. But that is a detail. The important point is—according to *The Call*, which got its information from a consular report—that "the geological structure of Mysore state is mainly hypogene schists penetrated and broken up by plutonic and trappean rocks in every form of intrusion and overlaid with occasional patches of laterite and the kankar calcareous deposit." All of which, on the face of it, seems highly probable; in fact, it could scarcely be otherwise. What a geological saturnalia! It is almost as bad as the recent description of a vein at Rawhide as "a core or deposit well defined by granite contacts with a porphyritic or sedimentary filling. This is not an igneous upheaval but a pure and simple sedimentary hot water or geyser deposit, divided by 15 porphyritic feet wide." You pay your money and take your true granite dikes, with a filling of from 250 to 300 choice.

THE KANSANSHI copper deposits, as described in an interesting article by Mr. J. R. Farrell, published elsewhere in this issue, evidently present a problem in ore-genesis which remains for later investigators to solve, but it would seem that the existence of immense masses of ore is assured. A point in this connection, with which many experienced engineers will sympathize, is the defense that Mr. Farrell offers for the manner in which his original conclusions concerning the probable importance of these deposits were reached under conditions which prohibited careful sampling and demonstration of the size of orebodies available. Subsequent developments have vindicated his judgment, and this suggests how valuable may be the opinion of an engineer of wide experience even when based upon a hasty reconnaissance. But it is dangerous, nevertheless, and such practice is not to be commended for frequent imitation. The line between realization of the significance of facts, which may at times be pregnant with meaning to the right man, and the intuitions of the wrong man, is one that must be drawn by the engineer himself. He may err in drawing it, and the safer way is to leave such methods as a resort in extreme cases only, like the one presented in this instance, where it was a question between that or nothing. Apart from this the article is valuable as a reliable statement of the great possibilities of Central Africa as a future producer of copper.

Timber and Mine Costs.

THE SERIOUS EFFECT which the drain upon our national forests will exert upon costs of mine operation in the near future appears from the fact that recent estimates by the United States Geological Survey, in co-operation with the Department of Agriculture, indicate the existence within the United States of timber sufficient for only 33 years, granting as a maximum that the standing stumpage will reach fourteen hundred billion feet, and that the annual growth will amount to forty billion feet. This estimate is based upon the continuance of consumption at the present level of one hundred billion feet per year. The expansion of industry and the temptation to large lumber production under the stimulus of increasing prices, will inevitably swell the consumption, in spite of the substitution of other material for timber. The quantity of timber consumed in the mines of the country has not been accurately ascertained, but round timber to the extent of 165,000,000 cubic feet, equivalent to approximately two billion feet board measure, has been traced. This represents only a fraction of the actual consumption in the mines. In the East it is probable that a large increase in the present high prices will compel resort to substitutes more extensively than in the West, where the quotations on timber appear small by the side of Atlantic sea-board rates, so that Western prices may double before it will become more economical to apply steel and other substitutes on a large scale. The chief reliance of the Rocky Mountain region, and of the West Coast, is upon Douglas fir, popularly known as Oregon pine. The total stumpage of this timber available, according to the highest estimate, is three hundred and fifty billion feet, which would be exhausted at the present rate of cutting in 70 years. It is assumed that the output of this lumber will rapidly double and will reduce the time-limit for exhaustion to about thirty years. A corresponding advance in prices is inevitable.

As an evidence of what this would mean to the mines in the West, the operating expenses at several representative properties show that the expenditure for timber ranges from 15 per cent of total costs in the desert region, to 5 per cent in mines favorably situated near to the great forests of the Northwest. In one large Colorado property the item for timber

is 28 cents out of a total cost of $2.07 per ton of ore extracted, or 13½ per cent. With prices for timber doubled this single item would then rise to 23.8 per cent of the mine-costs per ton of ore. At the Yellow Aster mine in the arid region of southern California a report was given out several years ago, when timber was selling at prices far below those of the present day, indicated an outlay on this account of 18 cents in a total cost per ton of ore of $1.16, or 15.5 per cent. A doubling of timber prices would in this instance bring up the percentage of costs per ton for this item to 27 per cent. At the Bunker Hill & Sullivan, where costs have been hammered down under efficient management to $1.46 per ton, the timber item is 15.7 cents, or 10.75 per cent. A like change in the timber market, other costs remaining fixed, would elevate this to 19 per cent. It is evident that not only must increasing attention be directed to the introduction of mining methods admitting to a greater extent of the omission of timber-supports, but in shafts and gangways, and other permanent openings, the use of creosoted timber should be encouraged. This would effect economies by prolonging the life of the timber at least four times beyond that of untreated material. Incidentally, such are the intricate correlations of industry, an important demand for creosoted timber, which will call into existence treating plants at the great ports of the Pacific Coast within the next few years, will stimulate by-product coking in the Western coalfields by offering an additional outlet for the tar derived as a by-product from retort-coking, and this in turn will promote the utilization of the surplus sulphuric acid which the smelting companies are compelled to produce in the abatement of the smoke nuisance, by its conversion into ammonium sulphate with the ammoniacal liquors constituting an additional important by-product from coking.

The Falls of Niagara.

THIS is the title of a book published recently by the Geological Survey of Canada and reviewed, most adversely, by us in our issue of February 22. It is a report by Dr. Joseph William Winthrop Spencer. Since the publication of our criticism, the matter has been brought before the Canadian House of Commons and the Minister of Mines has been asked sundry pertinent questions. Furthermore, we learn, from several correspondents, that Mr. Frank J. Nicolas, the editor of the Survey publications, has been dismissed, and that he is charged with having written the offending criticism. Therefore, an explanation is necessary.

The report came to us in the ordinary course of exchange with the Geological Survey of Canada. Our readers need hardly be told that no destructive criticism of any book would be published in our columns if contributed from the outside. This was done recently by the London *Mining Journal*, which printed a mean attack on the excellent treatise on 'Dredging for Gold in California' by our friend Mr. D'Arcy Weatherbe, the attack emanating from the author of another book on the same subject. As regards the review of Dr. Spencer's report, that was written, wholly and entirely, by the editor of the MINING AND SCIENTIFIC PRESS, who abominates pseudo-scientific balderdash whether it appears on the glossy pages of a beautifully printed volume or on the wrapping paper of an irresponsible daily periodical. In reply to questions concerning the publication of Dr. Spencer's report, it has been stated by the Minister of Mines that it cost $5148.69, which is about three times the usual cost of publishing a scientific treatise of a kindred character. However, we are not surprised at the cost, for the mechanical part of the publication must have been as expensive as it was excellent. The report is well printed and beautifully illustrated, far beyond the merits of the matter it contains. From the same authority we learn that Dr. Robert Bell made the original agreement with Dr. Spencer; that when Dr. Low became director of the Survey he questioned the advisability of publishing the report; that Dr. Low found it impracticable to evade publication; that the editor of the Survey found it difficult to revise; that finally "the author undertook to have it put into good English and properly published, agreeing to absolve the Survey from any criticism as to form and matter." The report was in print before Mr. R. W. Brock became acting director. All of which indicates the presence of those political undercurrents that impede honest men in the performance of their duty. We are in receipt of a letter from Dr. Spencer addressed to the "manager" of this journal, protesting against the action of the "editor." Fortunately, the editor of the MINING AND SCIENTIFIC PRESS is not subject to dismissal for doing *his* duty, as was the fate of Mr. Nicolas. Unfortunately, the reports of the House of Commons debates are themselves badly in need of proof-reading, for the pages sent to us exhibit a large number of typographical errors calculated to make the quotation of our criticism appear as cryptic as the report criticized. But that is no fault of ours. Dr. Spencer objects to the excerpt of seven paragraphs "which were grammatically correct and comprehensive, and were selections disconnected from their context." This is an objection that we had weighed; such excerpts are apt to do injustice to an author and that is why we made them rather long. If any reader doubts the fairness of our sampling, let him get the report itself, by writing to the Director of the Geological Survey of Canada. We are willing to abide by the judgment of any qualified man. Then let him enquire at Washington and at Albany, whether the report was not offered to the Surveys of the United States and of the State of New York before it was underwritten in Canada. The Minister of Mines himself admits that Dr. Low advised against the publication of the report. We can only add that no such perplexing and confounding semi-scientific material should ever have been accepted, no matter what political pressure was brought to bear, and we hope that the people of Canada will see to it that Mr. Nicolas receives just treatment at the hand of the Minister of Mines, a member of a government already notorious for corruption.

Personal.

ALFRED JAMES has gone to South Africa.

VICTOR G. HILLS is at Telluride, Colorado.

WALTER C. BRACE, of Denver, is in Nevada.

HERBERT HAAS is in Mexico for a few weeks.

EARL R. PEMBROKE has been in Montana recently.

OSWALD STEIN is now resident at Goldfield, Nevada.

JEROME B. LANDFIELD is at Cannes, in southern France.

FRED. S. PHEBY is in San Francisco from Ely, Nevada.

THOS. B. STEARNS, of Denver, was at Goldfield this week.

A. H. ELFTMAN, of Tonopah, spent a few days at Goldfield.

H. A. SHIPMAN, of Denver, is at Rico, Colorado, for a week.

ARTHUR L. PEARSE is expected at Seattle, on his way to Alaska.

C. G. PATTERSON has returned to San Francisco from Mexico.

W. J. LORING left London on April 11, on his way to San Francisco.

FRANK PETERSON, of New York, is operating at Manhattan, Nevada.

M. B. ZERENER was at Goldfield recently, and is now at Ely, Nevada.

POPE YEATMAN is expected at Ely. On April 25 he will go to New York.

H. V. WINCHELL has recovered from his accident and is now at Butte.

F. L. MORRIS, on his return from Seattle, went to Silver Peak, Nevada.

GEORGE W. PEIRCE is with the Nevada Goldfield Reduction Co., at Goldfield.

FRANCIS A. THOMPSON has returned to Pullman, Wash., from the Coeur d'Alene.

CHAS. W. MILLER, who is mining in Tuolumne county, California, is at Denver.

A. B. ROMBAUER is manager of the Ingram mine at Salina, in Boulder county, Colorado.

RALPH NICHOLS is on his way from Durango, Mexico, to his home at Aurora, Illinois.

LLEWELLYN HUMPHREYS has arrived in Goldfield on a reconnaisance from Ely, Nevada.

JAMES LINDSEY, of New York, is in San Francisco, having recently visited Rawhide, Nevada.

CHARLES HOYLE succeeds W. E. HINDRY as manager of the Esperanza mine, at El Oro, Mexico.

L. E. BEDFORD is manager of the Republic mine, at Graniteville, in Nevada county, California.

ARNOLD BECKER has been critically ill with pneumonia at Goldfield, but he is recovering satisfactorily.

C. W. WININGER has become assistant superintendent of the Amparo mine, Etzatlan, in Jalisco, Mexico.

E. D. LACHMAN has severed his connection with Charles Butters & Co., and has gone to his home in Reno.

ERNEST R. BUCKLEY has resigned as State Geologist of Missouri to accept a position with the Federal Lead Company.

J. WALTER GEDDES is manager of the Daisy mine at Goldfield. He has just returned thither from Oroville, California.

OSCAR LACHMUND has left the United States Smelting Co., at Salt Lake, to become manager for the Mine La Motte company, in Missouri.

J. PARKE CHANNING sailed for Europe on April 14, accompanied by ADOLPH LEWISOHN. They will visit Paris, Berlin, Hamburg, and London.

FRED. L. JOHNSTONE, of Santa Barbara, passed through San Francisco last week, bound for Reno, Nevada. He will later make professional visits to several Nevada camps.

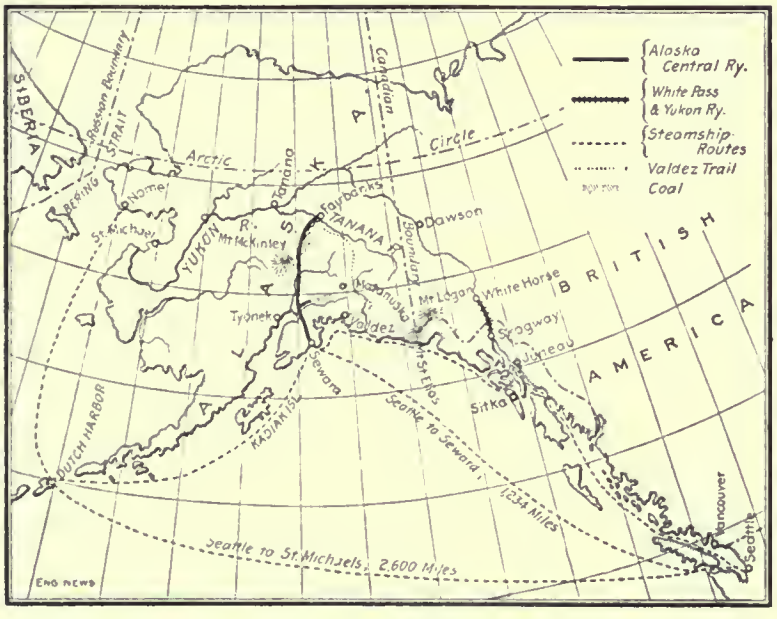
Obituary.

JOHN H. MORCOM, superintendent and one of the owners of the Colorado Iron Works, died at Denver of apoplexy on April 8. He had been with the Colorado Iron Works Co. for the past 25 years, and had many friends in the mining fraternity, both in the United States and Mexico. He leaves a wife, son, and daughter. He was 60 years of age at the time of his death.

General Mining News.

ALASKA.

(Special Correspondence).—Several discoveries of quartz mines have been made on the Seward Peninsula, and a custom mill and sampler will be erected at Nome during the summer.——Representatives of the Guggenheims are stated to have been in the Koujarok last summer, and at least two ditches with unlimited water facilities were acquired with which to carry on placer operations on a large scale. The big electric dredges on Bourbon creek, at Nome, is nearly completed and work will begin early in July. Another big dredge of 2000 cu. yd. capacity per day will be installed on Dry creek, near the Third Beach line, next season. The next mining camp stampede will probably be to Siberia this fall. John Rosene, of the Northwest Siberian Mining & Trading Co., has acquired 500 square miles of the Chuckchi peninsula by a concession from the Czar of Russia. Last year great quartz and placer regions were explored, with wonderful results as to the richness of the country in gold, silver, and copper. A steamship line will operate this summer between Nome and East Cape, and



Map of Alaska.

the various trading ports of the company near Plover bay. It is given out that American miners will be invited to take up and work mining claims in Siberia on a royalty of 10%. Many people are already preparing to go into the country as soon as navigation opens. Word received in Nome from Fairbanks indicates that sluicing operations were carried on this winter until January 16 on Cleary creek. Three feet of gravel on the Oakdale claim of Berger & Sullivan, on Sunset creek, averages 75c. per ton. The pay-streak is in an old stream channel and has to be kept dry by Mammoth pumps. Sixty-five men are working two shifts per day. Newton and Bowles, two Nome prospectors, have found a valuable quartz mine on the Chandelar.

Nome, April 1.

ARIZONA.

YAVAPAI COUNTY.

(Special Correspondence).—The Monte Cristo property, on Groom creek, has resumed operations. About 15 men have been started to work, and more will be added as soon as the mine is unwatered, which is being done as rapidly as possible. The company's stamp-mill is also receiving a thorough overhauling, and will be started in the near future.——Development work will be resumed at once on the Empire mine. A force of mechanics has already begun to repair the machinery and to unwater the shaft.——W. F. Shaw and others, who are developing a group of claims on Wolf creek, report satisfactory progress in the adit being run to cut the main vein.

Prescott, April 12.

CALIFORNIA.

NEVADA COUNTY.

(Special Correspondence).—The Central shaft has passed the 5300-ft. level. A large station has been cut at the 4500 level and three tracks laid. Extensive development work is going on at several points in the lower workings. The vein is showing splendidly at great depth.——A small shaft is being sunk at the Spring Hill mine to connect with the 1500-ft. adit and furnish better ventilation. The adit will be continued for a considerable distance. The vein is four feet wide. The ore is of fair grade.——The Pittsburg Standard M. Co. has forfeited its bond on the Norambagua and the property has reverted to its former owner, George Campbell.——Sluicing has started at the Posey Canyon. A large quantity of loose gravel, rich in gold, is available. ——A. D. Foote has abandoned the bond on the Williams-Ryan-Whiting claims, as a shipment of the ore to a smelter disclosed that the ore was not of good enough grade to warrant working. Foote still holds the Mason ranch and an adjoining 80-acre tract. Williams and associates state that the vein is valuable, and will work it on their own account.——A small quartz vein has been found in the Jenny Lind mine. A large quantity of rich gravel is being developed. Much of the gravel is cemented. ——The shaft at the Kenosha has been unwatered and extensive driving is under way on the 400 level to intersect the rich oreshoots struck at the 300-ft. point.——Sinking progresses steadily at the Normandie in fair ore.——Sinking is still going on at the Midas, and it is thought that the lode will be encountered soon.——Work at the Aurora is going ahead steadily.——Ore is coming from the 200 level in the Golden Gate, and the shaft below that point is being rapidly unwatered. As soon as the vein at the 400 level can be reached driving will be commenced. —— Henry Eckhardt of San Francisco and E. A. Work of Nevada City have bonded the Serius group of claims in the Washington district. Work on the mine will start at once. The bonders expect to install a 10-stamp mill in the near future.——Work will soon be resumed on the Neversweat mine in Willow valley. ——The German mine will be re-opened and extensively developed during the coming summer.——A large force of men is working at the Mountaineer. Good ore is being developed at several points.——W. J. Organ has struck a rich shoot of ore on his claim near the Murchie mine. The discovery was made at a depth of 100 ft.——It is announced that work will be resumed at the Cold Springs and Buckeye mines within a few days. A tunnel will be driven to connect the properties. Thomas Coan is superintendent.—— The Grass Valley Miners' Union has decided to affiliate with the State organization of the Western Federation of Miners.

Grass Valley, April 13.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The first clean-up of bullion at the Hathaway mill, recently erected by the Empire T. Co., was made last week, and it was found that a saving of 92% was made. The average value of the ore being treated does not exceed $5 per ton, while the cost of mining and milling is low and gives a good profit. It is now practically assured that the sulphide ores surrounding Empire can be treated at a handsome profit by the Hathaway process, and as a result a number of owners of mines are going to start work upon milling plants which will be similarly equipped. ——The Charter-Raton M. & M. Co., operating on Breckenridge Mtn., is employing a good force of men in driving the

La Moe adit. The bore is in 950 ft., and progress is being made at the rate of from 4 to 5 ft. per day. According to surveys, the Charter vein will be reached within 50 ft. J. J. Bonner of Georgetown is superintendent.——The Puzzler mine on Young Mtn. is undergoing systematic development and a fair tonnage of ore is being broken. A streak of high-grade gold-silver ore that measures from 12 to 18 in. wide is being stoped, and shipments will soon be made.—— The Coffin mine is producing ore of good grade, the average value of which is $45 per ton. A body of mineral is exposed that is from 4 to 5 ft. wide. It is understood that during the summer months a concentrating plant with a capacity of 25 tons daily will be installed. The Tyler adit is being steadily driven forward, having been advanced 310 ft. Three veins have been intersected, and all show more or less mineral. Driving is in progress upon lode No. 2, and a number of stringers of high-grade ore have been found. T. Tyler is general manager.——The Collins group of three claims and a mill-site is undergoing development. The adit has reached the 400-ft. mark, and a small streak of heavy lead ore is showing. The junction of lode No. 2 will be reached within 30 ft. This property, which is situated on Leavenworth Mtn., recently passed over to the Premier G. M. Co., an Eastern corporation. Alfred Martin of Silver Plume is superintendent.——The Shively adit has been advanced to within 85 ft. of the objective. Great care is being exercised to avoid danger to life, as all of the old maps of the Shively workings have either been lost or destroyed. This adit will tap the 500-ft. level of the Shively shaft, opening for exploitation a vast area of virgin ground.—— Sprousse & Jameson, in charge of the Waldorf M. & L. Co. operations, shipped 12 carloads of $60 silver-lead ore this week.. The ore was sent direct to the Argo smelter in Denver for sale. Work is being prosecuted on the Commonwealth vein, intersected 4800 ft. from the entrance of the Wilcox adit. The ground has been opened for 800 ft. in length, while a stope 200 ft. long is being carried. A body of ore is being followed that measures from 18 in. to 3 ft. in thickness.——The Argentine Central Ry. is again open for traffic, having been snow-bound since the first of last December. Heavy shipments are being sent out from the East Argentine district, and the capacity of the road is being taxed.——The Miller adit on Saxon Mtn. has intersected the extension of the Choctaw vein, whence a heavy production was made a number of years ago. A streak of high-grade ore is showing that is from 12 to 14 in. wide, and a recent sampling gave $78 per ton in silver and lead. ——The Silver Leaf adit on Leavenworth Mtn. is being driven steadily forward, having been advanced 1100 ft. Driving has been started on lode No. 3, and a 4-in. streak of heavy lead ore is being followed. B. J. Martelon of Silver Plume is in charge of the work.——The showing in the Sporting Times mine, Griffith and Alpine Mtn., is improving at a rapid rate. A heavy tonnage of high-grade ore is being mined, the average worth of the same being $87 per ton. The streak measures from 8 to 12 in. wide and the continuity of the shoot has been proved for 35 ft. Stoping has been started and shipments are to be begun next week. A. H. Colburn is owner and operator of this property.—— A 12-in. streak of ore has been uncovered in the winze being sunk on the Silver Cloud, which is being operated through the Victoria adit, Sherman Mtn. The winze is down 35 ft. and as soon as the lift has been completed to the 50-ft. point drifts will be run east and west. From a recent shipment returns of $97 per ton in silver and lead were received.—— Heavy shipments are being made by B. J. O'Connell, leasing 150 ft. below the Victoria adit level on the Mendota. Stoping is in progress upon a streak of lead-zinc ore that measures from 2 to 5 ft. wide, and after separation the lead product averages $70 per ton. No shipments of zinc have been made for several weeks, owing to the low price being paid for that metal.

Georgetown, April 12.

FREMONT COUNTY.

The Empire Zinc Co.'s works are now running at full capacity, after having been partially closed for some months. The United States Smelting Co. is operating again with all its furnaces.

MONTROSE COUNTY.

Surveys have been completed, and it is stated that work shortly will be begun on the construction of a narrow-gauge railroad which is to connect the Denver & Rio Grande railroad at Montrose, Colorado, with the mines of the La Sal Copper-Silver Mining Co. at Cashin, a distance of 70 miles. This road, which will be in operation in a few months, will enable the company to send out its ore at an expense of $2 per ton, as against a charge of $22 per ton for the wagon haul over the present State road. No more ore will be shipped until the railroad is completed, and that which is now being mined is being piled on the dumps, where there is enough ore already to keep the railroad running for several months. Development work is now being actively continued. On the Red Chief the adit has been driven over 1300 ft., and the shaft is in 165 ft. below the adit. Drifts have been run 50 ft. each way at the 100-ft. level, and all are in ore.

PITKIN COUNTY.

The miners have returned to work at the Smuggler and Durant mines, having agreed to accept a temporary reduction in wages equal to about 25c. per day. About 400 men are affected. The properties are large zinc producers and the reduction of wages is due to the low price of that metal.

ROUTT COUNTY.

At the Colorado Mines & Water Co.'s property near Lay, preparations are being made to start the season's work. The ground is being cleared for the dredge, and supplies are being brought in from Rawlins and Rifle. Coal of excellent quality is being opened up and hauled to the dredge..

TELLER COUNTY.

Last Dollar on Bull hill has again entered the producing ranks, under the able direction of the Western Investment Co. During the month of March 22 cars of good-grade ore were shipped. Practically all the levels are being worked. At present there are six sets of sub-lessees operating on the property, most of whom are in good ore. A large amount of development work is in progress. Another property that has recently been taken over by the Western Investment Co. is the Dexter, adjacent to the Last Dollar. The lease was taken since the first of April, but the company is already hoisting some ore.——The annual meeting of the M. & M. Co. was held in Colorado Springs last week, showing an exceedingly prosperous condition of affairs. Net profits of $78,486 were earned during the year, of which amount $75,000 was distributed in dividends among the stockholders. The principal source of revenue was the royalties on the lease on the Little Clara claim, operated by A. E. Humphreys and associates, which amounted to $79,025. In addition, the company received $11,833, this being its 25% share of the terms of the contract. Eleven other lessees are operating on the property. The treasurer's report shows a cash balance on hand of approximately $85,000, against which there stands $6429 due for taxes August 1, and $3500 due in various installments for the Cripple Creek drainage adit.

IDAHO.

IDAHO COUNTY.

The Thunder Mountain mine is being developed, and some ore has been found both west and east in No. 4 adit. The west ore-shoot has been followed for 75 ft. and there is 8 ft. of ore in the heading. A raise has been put up 78 ft. in ore. The east ore-shoot has a face of 9 ft. at a depth of about 310 ft. from the surface. An adit is now being run south from No. 3 adit to intersect this body of ore. As soon as the boiler is installed the mill will be run continuously.

SHOSHONE COUNTY.

(Special Correspondence).—The Snowstorm mine has made a contract with the Amalgamated Copper Co. at Anaconda, Montana, for 100 tons additional to be sent to the Washoe smelter. The Amalgamated has been taking an equal amount for the smelter at Great Falls. With this in-

crease the Snowstorm will now be sending about 400 tons per day to six different smelters of Montana, Washington, and British Columbia. Preparations are now being made to increase the output, as the resumption of smelting in many plants which are now operating a portion only of their furnaces, will necessitate the purchase of more of this silicious ore.——J. H. Ehlers and associates have paid $10,000 more on a $125,000 bond for the Black Bear Fraction property at Black Bear, Idaho. The property is being steadily developed by three shifts, work being concentrated in the deep-level adit, which is expected to strike the Standard ore-shoot, which is believed to cross the Black Bear Fraction property.——It is stated that the Federal Mining & Smelting Co. is soon to reopen its sampler, which was closed last fall. A large tonnage of ore is awaiting treatment at Mace. It is also believed that the Last Chance mine, which made a show of starting some time ago and then withdrew its crew, will resume operations.

Mullan, April 11.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The constantly increasing output of the Missouri-Kansas district in the face of a declining price for zinc concentrate has been one of the features of the year's events in this field. In January the weekly production averaged 3630 tons, in February 4036 tons, in March 5430 tons. During the past two weeks the surplus ore that has been accumulated has been largely absorbed. In addition, the activity of buying agents has been more pronounced than at any time for the past six months. Prices, however, for zinc concentrate have been declining in the face of a greater demand until this week showed only $32 per ton for 60% zinc. A few bins sold at a higher base price, but the majority of sales were settled on a base ranging from $32 to $33 per ton. On the contrary, lead ores have been advancing in price. From a minimum of $45 it has passed the $54 mark, with buying exceedingly strong. The result has been great activity among the small producers of lead ores. These small producers being men that were formerly employed in the mines of the larger companies have become operators themselves and have taken up leases in the shallow lead districts, showing that men with a practical knowledge of the mines of this field can take care of themselves at the present low prices, even if the larger properties fail. This has resulted in great activity among the old hollows west of Joplin and along Shoal creek, south of the city. In Leadville Hollow a small company of prospectors took up the lease of the old Arkansas mine, which had been unsuccessful as a mill proposition, and have developed it into one of the best lead and zinc producers of the camp. The property was formerly worked at 165 ft., where the water was especially strong, while the present operators began work on the 145-ft. level, where it is dry. The company has now opened a face of free ore 18 ft. high and 30 ft. wide. A similar occurrence took place at the Hancock mine. This company ceased operations, alleging that the mine was unprofitable as the orebody was too lean. The employees of the mine then leased the ground and mill, and upon driving a new prospect drift opened a face of high-grade zinc-blende. The property is now producing from 30 to 100 tons of concentrate weekly.——The development of the Lounetta ground was brought to the producing stage last week by the starting of the new 150-ton concentrating plant. The company is operating a 12-acre lease, upon which drilling revealed a body of lead and zinc ore 52 ft. in thickness. The shaft was then sunk, which fully developed the drill findings. The property was then worked by hand-jigs for some time, and was a bonanza producer of lead ore until the erection of the mill, in which the zinc ore is treated as well as the lead ore. On an adjoining tract the Barnard Mining Co. has drilled the ground and found the ore at the same level. A shaft is now being sunk to develop the orebody. A concentrating plant will also be constructed.——The Missouri Metals Corporation has purchased the mine and mill of the Pittsburg-Missouri Co., adjoining the old Baltimore ground in Chitwood. The land has been recently drilled and the lease found to be underlaid with a body of sheet-ore. Two shafts have just been finished and the property is now producing ore.——The extension of the Joplin camp to the northward has been accomplished by the development of the Bartlett land by the Cameron Mining Co. A tract of 53 acres has been thoroughly drilled, and a number of holes penetrated an orebody at 146 ft. The shaft that was sunk to develop the lease entered ore at 98 ft., and was in ore to 146 ft., where it again entered barren rock. When driving was started on the 146-ft. level rich ore was developed, and the mine became a good hand-jig producer all through the stages of development. A concentrating plant will be completed this week. The plant is equipped with electrical power and will handle 150 tons per 10-hr. shift.——The Herald Mining Co., operating one of the largest leases in the district at Cave Springs, has closed down its plant in order to tear out its jigging machinery and substitute another form of jig especially adapted to its ore, which is uncommon for this field, as instead of a chert gangue, the ore occurs in a sticky limestone highly dolomitized. The underground work was not interrupted at all, and the ore hoisted is being stored, awaiting the completion of the installation.——Southeast of Joplin, at Tipton Ford, an unusual amount of prospecting has been in progress the past two months, resulting in the opening of a number of new orebodies. On the Barbee-Gregg land, Donahue & Jenkins put down a number of drill-holes, all of which penetrated two runs of ore. In one hole a continuous run was found from 15 to 150 ft. A shaft has been started on this hole.——On the Newdigger land a surface deposit of lead carbonate has been discovered and followed back into the hill some 50 ft. A shaft 6 ft. deep only 100 ft. away opened a similar deposit. These deposits are among the richest shallow discoveries ever made south of Joplin.——On an adjoining tract, belonging to Murphy & Hewett, drilling has developed two runs of ore, one from 20 to 45 ft. and a second 120 to 180 ft. The cuttings showed both galena and zinc-blende.——On the Armil land, on Shoal creek, Jack Armil and associates have developed a deposit of zinc-blende at the 165-ft. level. The strike was made in new territory. The ore runs 11% zinc-blende, and will be treated in a new concentrating plant in course of erection.

Sketch Map Showing Position of Joplin.

Joplin, April 13.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—Through the broad-mindedness of both mine owners and their employees, the possibilities of a strike have been averted and mining operations have again settled down to a progressive basis in the Seven Troughs district. The operators recently declared their intention of reducing the wages from the $5 flat rate to the scale adopted by the Consolidated companies of Goldfield. The miners' union immediately sent delegates to confer with representatives of the mine owners, and succeeded in effecting a compromise which seems highly satisfactory to both parties. The scale adopted is graduated as follows:

Muckers and top-men receive $4 per day; miners for drifts and stopes, $4.25; for shafts and raises, $4.50; engineers, carpenters, and blacksmiths, $5; all wet work 50c. per day extra. With this question settled, nearly all of the developing properties have resumed work, with several new enterprises coming to the front. As a result, numerous rich strikes have been reported during the past week.——The Kindergarten has further increased in value by disclosing another ore-shoot in the east drift from the 125-ft. level that far surpasses any of the ore thus far extracted. The occurrence is in a hard quartz containing sulphides and free gold. The mill for this company is rapidly nearing completion, and it is the expectation of the owners to have it in operation early in May.——The hoisting equipment and head-frame for the Gaynor lease has been erected and will be in operation within a few days.——The Stoker lease on the Therein has encountered a high-grade streak on the hanging wall of the incline at a depth of 225 ft. and is stripping the adjacent material until a sufficient amount has been uncovered to extract for shipment.——On the Mazuma Hills great activity prevails. The mining company has again started development work, after clearing away the shipping ore during the recent shut-down, and is increasing the working force preparatory to supplying the mill, which is to be completed at an early date.——The Reagan-Hayes lease, at a depth of 27 ft. in the winze from the 65-ft. level about 150 ft. north of their working shaft, has opened a rich shoot of ore ranging in width from 8 to 20 in. A nugget extracted a few days ago weighed about 1½ oz. and showed but little gangue. A carload shipment went out from this property early in the month.——The Arnett-Potter lease, lately acquired, has by a system of trenching exposed a lode which is thought to be the one on which the mining company is working. Several small specimens showing free gold have been found, while the lode pans across its entire width. A guarantee of $10,000 for development purposes was required by the mining company before the lease was granted.——A block of ground was this week let which means much for the economic importance of the camp. It has been acquired by G. H. Hayes and associates of Goldfield, and lies between the Reagan-Hayes block and the Mazuma Hills main tunnel. A lode has already been exposed showing good ore, and with development it is thought some important finds will be made. It is understood the parties in possession will start active development at once. Other lessees on this property are making good headway and proving the presence of a fair grade of milling ore. Most of the leases are for two years.——The George-English lease on the Fine Gold in an open-cut west of the lower adit has opened a 12-in. stringer, 6 in. of which is of high grade.——Reports come from the northern and southern ends of the district of rich finds on the Little Hero, Cæsar, Golden Treasure, Annie, and Big Dipper claims, at Farrell and Vernon.

Seven Troughs, April 14.

ESMERALDA COUNTY.

A contract has been signed for a 600-ton Butters patent vacuum-filter plant of 300 leaves, for the Goldfield Con. Mines Co. at Goldfield. This equipment is to be ready for operation by Nov. 1. F. L. Bosqui is consulting metallurgist to the company.——From the Tonopah district there was shipped 3925 tons of ore during the week ending March 31, according to the report of the Tonopah & Goldfield railroad. The following mines contributed: Tonopah Mining Co., 2789 tons to the mill at Miller; Belmont, 733 to the mill at Miller; Midway, 189 to the Belmont mill; Tonopah Extension, 101 to the Western Ore Purchasing Co.; MacNamara, 50 tons to the Western Ore Purchasing company.

LINCOLN COUNTY.

A discovery of rich galena and gold-bearing quartz has been made in Eldorado canyon, near Nelson. An 18-in. vein of solid galena and a quartz vein showing free gold have been found by prospectors, who are now developing the find. The claim is just west of the McGann mine. Nelson is 20 miles north of Searchlight and 35 miles east-southeast of Las Vegas.

NEW MEXICO.

SIERRA COUNTY.

(Special Correspondence).—The Good Luck mine is now operating with 30 men, doing development work. Another body of lead and silver ore was found and the outlook is encouraging. Later on they expect to erect a 100-ton mill to treat the ore from the mine. The ore runs high in lead and silver. About 900 ft. of development work has been done in ore. J. H. Elspass is manager and T. J. McKenna superintendent.

Lake Valley, April 2.

OKLAHOMA.

OTTAWA COUNTY.

The development of the Oklahoma ore deposits began in 1904 with the erection of two concentrating plants; in 1905 three more were added; in 1906 there were 16, and in 1907 there were 25 plants with a capacity varying from 100 to 300 tons. This increase in number of plants, however, has not been so productive of ore as many of the smaller camps with a less number of mills. The camp south of Baxter Springs, which was first developed, has proved to be well mineralized territory, and the deposits of ore are large.—— Many of the mills were idle for months, owing to bad management, but recently a better tone seems to have come to the camp, and a number of the properties are being worked by better methods. As a result there is rising up in the whole camp a number of small producers that are developing ground without expending money for plants before they are needed. The Dark Horse property is now being operated with hand-jigs with good results, while the Mozaska, northeast of it, is also a good producer on a small scale. There are other properties that might be placed in a productive state if the operations were confined to the actual production of the ore as development was carried on, instead of selling stock and building concentrating plants before the orebody is sufficiently developed.——The latest development is being done north of Miami, where some rich properties have been indicated by recent drilling and shaft-sinking. The New State lease has sufficiently developed the ground to show a large body of workable ore. The ore occurs in connection with a large quantity of bituminous matter, which makes its separation a hard proposition, but the percentage of ore to the gangue runs high, thus insuring a large return if the separation is complete.——The Gordon Mining Co. has sunk five shafts to an orebody that was discovered by drilling, and has now erected a 300-ton concentrating plant.——The Old Chief property has also been developed and a concentrating plant has been erected.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Copper Key Mining Co. is applying for patents for the Copper Key, Triune, Maggie Fraction, Spokane, Aunt Spokane, Uncle Spokane, and Sister Spokane lode claims on Belcher Mtn.——The Summit M. & M. Co. is about to resume work on the Summit mine. The company owns a group, of which the Summit is the principal claim. A shaft is down on a quartz-vein, in which small deposits of high-grade copper and silver-lead ore occur. Two levels have been opened, the deepest being about 150 ft. below the collar of the shaft. On the lower level there is a chance to open up a good pay-shoot. The Keller & Indiana Con. Smelting Co. is about ready to blow in its furnaces and buy ore. A contract has been let for haulage of coke from Creston, a point 22 miles distant on the Washington Central railway.——The Byrne Co. has developed a body of ore assaying about $30 per ton and is following it on the adit level.——The Illinois Copper M. & M. Co. is driving an adit on the vein and reports a gradual improvement.——At Park City the Hercules adit is in 410 ft. and getting into the vein, but no ore has yet been found. ——The first carload of ore from the Railroad mine, two miles north of Laurier, will be shipped as soon as the wagon-road to the railway is in good condition for haulage. ——The Little Kitten mine, under operation by the Mohawk Co., on the west side of Kettle river, is showing up better

than was expected and promises to make a good paying venture.

Republic, April 11.

OKANOGAN COUNTY.

(Special Correspondence).—Men have been put to work drilling out the frozen charges of the Sullivan smelter, which led to the supposition that the smelter was to resume. One furnace may be blown in to dispose of the surplus ore, amounting to about 2000 tons, but after that is disposed of the plant will be shut down indefinitely. The mines will not be operated until the price of lead is high enough to warrant the treating of the refractory ores of the district.

Spokane, April 11.

CANADA.

ONTARIO.

(Special Correspondence).—The policy of developing its silver veins at depth, instead of mining from the surface, as practiced by many of the Cobalt properties, is beginning to bring good results to the Cobalt Central management. At the No. 2 level of the Big Pete shaft five veins are now being worked and high-grade ore extracted, whereas on the surface these veins were worthless. The richness of the ore in the low levels is shown by the result of the operations of the Cobalt Central's concentrating plant on April 2, when from 47 tons treated the yield in silver was 27,350 oz., valued at $15,179. On Lot 38 of the Cobalt Central mines a new vein has been stripped on the surface which shows a width of 20 ft. of good concentrating ore. A shaft is being sunk on this vein for the purpose of developing it at depth.

BRITISH COLUMBIA.

Regular shipments of bullion and high-grade concentrates are being made from Hedley. The most important claims in the camp are the Nickle Plate and the Sunnyside, owned and operated by the Yale Mining Co., whose property also includes some twenty-five other claims. Upward of a million dollars has been expended by this company and its associate, the Daly Reduction Co., in developing the Nickel Plate and Sunnyside. While there is a large amount of underground development proving the orebodies in depth, the ore supply up to the present has been taken from large glory holes on the surface. These glory holes are simply large quarries cutting into the surface of the vein, which is fully 75 ft. thick and proved by the excavations to be continuous for a distance of over 3000 ft.. The ore is treated by the Daly Reduction Co. in a 40-stamp mill and cyanide plant in the valley below. The capacity of this mill is about 3500 tons per month. The mine and mill are run by water-power obtained from a flume three miles long. The company owns an electric tram line about a mile and a half long to carry the ore from the mine to the tipple, and a gravity tram-line about 10,000 ft. in length and some 4000 ft. vertical height, which carries the ore in 5-ton skips to the mill. It is an interesting fact that in the mining of these ores from glory holes all the rock has been put through the mill, without any discard as waste. The production of the mines last year in bullion was $700,000.——The Pollock mines, owned and operated by the Pollock Mines Co. Ltd., which lie on Henry creek, two miles to the west of Hedley, on the opposite side of the Similkameen river, have a considerable amount of development already done. ——The Kingston Gold Mining Co. has an excellent property adjoining the Nickel Plate group, which has been well explored and is now arriving at the shipping stage, and with the advent of the Great Northern to Hedley the Kingston will be a big shipper.——The Golden's Own, lying northeasterly from the Nickel Plate, which is well known as a valuable property, is now rapidly developing into a producer. It is owned by Marks, Broadhagen, and others, and is a free-milling property, similar to the Nickel Plate. Machinery is now on the ground for a stamp-mill, the work of getting material for construction is being rushed, and the mill is expected to be in operation in the early summer.

The adit in the Blue Bird is in about 70 ft., and the vein in the face is 4½ ft. wide and is all high-grade ore. The vein is strong and well defined from the portal to the breast of the adit. The work of extending the adit continues and is making better progress, now that a steam drill is being used. The lessees have requested the Columbia & Western railway to put in a spur at the Homestake, where formerly there was a spur. At present the ore has to be hauled to the Spitzee, a considerable distance, but when the spur is completed the ore will only have to be hauled a few hundred feet. W. Whitford and C. Jenkin have bought the quarter interest owned by W. Arscott in the lease. This gives them a three-quarters interest. Under the terms of the lease the most men that can be worked at one time is eight. The full number will be put to work just as soon as the spur is put in.

It will be seen that the Iron Horse joined the shipping list this week. This property has been leased to M. A. Henderson and associates.——A trial shipment of Cobalt silver ore has been made to the Trail smelter from the Nancy-Helen mines. The Cobalt smelting ore has heretofore been treated in the United States, but if it is found that it can be profitably treated in Western Canada, regular shipments will be maintained.——The Crescent mine, a Chicago enterprise, has ceased work. Their plan of operations is to be modified. A carload of high-grade ore was shipped from the property in February.——The old Blue Bell mine, on Kootenay lake, from which the early trappers got lead for their bullets, is to be worked on a larger scale this season. ——A London-Nelson syndicate has leased the Hall mine at Nelson and will begin work as soon as the snow goes off the hill.——The Big Bend Mica Co. has been organized to work 1400 acres of mica ground north of Revelstoke.

The Evancon Mine, in the Val D'Aosta. The Only Gold Mine in Italy.

Following is the tonnage of ore shipped from and crushed at the mines of Rossland for the week ending April 4, and for the year to date:

Mine.	Week.	Year.
Centre Star	3,960	46,598
Le Roi	1,680	23,734
Le Roi No. 2	490	8,418
Evening Star	31	428
Iron Horse	38	38
Blue Bird	....	30
Totals	6,199	79,246

The district shipments for the week were as follows: Boundary, 24,687 tons; Rossland, 6199; Slocan-Kootenay, 1476. Total for the week, 32,362 tons.——At the smelter of the Consolidated company there was received during the past week 5224 tons. Besides that which was sent from Rossland, ore was received from other mines as follows: St. Eugene, 419 tons; Snowstorm, 487; Richmond, 28; Rambler-Cariboo, 24; Nugget, 24; Whitewater, 46; Silver Cup, 335; Mother Lode, 15 tons. The Granby smelter received 24,687 tons from the Granby mines at Phoenix. The Le Roi smelter at Northport received shipments as follows: Le Roi, 1756 tons; First Thought, 63; total, 1819 tons.

Special Correspondence.

LONDON.

Rio Tinto Report.—Cause of Withholding Information.—Ooregum Gold Mining Co.—Condition of Oroya Brownhill Mine.

It is always regretted by mining engineers and metallurgists that the force of circumstances prevents the publication of details relating to the development of the Rio Tinto mine, and the methods of treating the ore. The management and direction of this mine are unequalled, and an account of the experience gained there would be of great value to everybody. The secrecy maintained is not due to personal whim, but solely as a safeguard against the rapacity of the tax collector. The Spanish Government treats the mine-owners of Huelva as aliens that should be taxed to the utmost, and taxes have to be paid almost every time the ore is moved during treatment. The publication of anything like a full description of the methods of mining and treating the ore would have the effect of bringing down a swarm of tax-gatherers. It is not only the Rio Tinto company that observes the policy of silence. The other English companies, such as the Tharsis and Mason & Barry, do the same. The chairman of the Rio Tinto, C. W. Fielding, has experienced similar difficulties, if not worse, in California, in connection with the Mountain Copper Co. Your readers are well aware how this company has been treated by the politicians. Consequently the report for 1907, just issued, gives as usual only a bare outline of the results. After paying all expenses and making liberal allowances for depreciation of plant, a net profit of £1,744,596 was made, of which £79,000 has been distributed as dividend on the preference and £1,640,625 on the ordinary shares, being at the rate of 87½%. This rate compares with 110% during 1905 and 1906, and considering the current history of the copper market, may be thought highly satisfactory. In fact, it displays the sagacity of the management in connection with their selling contracts. The amount of ore extracted during the year was 1,906,948 long tons, of which 641,858 tons were cupriferous pyrite intended for shipment to Germany, Great Britain, and the United States. The actual amount of this class of ore shipped during the year was 607,944 tons, of which 332,259 tons went to Germany, 116,035 tons to Great Britain, and 159,650 tons to the United States. Less goes to Great Britain than formerly, as the United Alkali Co., one of the chief customers, now possesses mines of its own in Spain. Of the remaining output, 1,265,090 tons was held for local treatment. Some of this is smelted, and the remainder leached. After the copper is extracted the leached ore is sold for its sulphur content. The total amount of copper produced during the year was 32,317 tons, of which 21,251 tons was produced at the works and 11,066 tons sold in the pyrite shipped.

After having suffered from drought for some years, the company now has to report that its water supply is in an extremely satisfactory state, owing to the unprecedented rains of the early winter. These rains caused the subsidence of part of the land adjoining the South lode and a great many dwellings were ruined. This caused some expense to the company in rebuilding houses elsewhere, but on the other hand the subsidence is welcome, as it allows of considerable economy in mining by an extension of the open-cast system. Walter J. Browning, well known in Mexico, was appointed general manager of the Rio Tinto last autumn, in succession to W. A. Carlyle.

E. H. Garthwaite in your issue of March 14 calls in question some remarks of mine relating to the population of Rhodesia. I am glad that any words of mine have been the cause of Mr. Garthwaite's sending you a contribution relating to the country in which he served the British South Africa Co. as chief engineer. Unfortunately, however, he has mistaken my point, and he is arguing on the same side as myself. The Government of Rhodesia has always deplored the scarcity of white settlers. On one occasion Generai Booth took them at their word and offered to ship out a large supply of 'out-of-works,' 'ne'er-do-weels,' and ex-criminals. Both the Government and the settlers themselves were immediately up in arms against such a proposition, and it was promptiy vetoed. My point is that the development of a new country is not as a rule done by the comfortable and respectable portion of the community, but by those who ieave their country for their country's good.

The Ooregum Gold Mining Co. has during the last six years worked on much lower grade quartz than the adjoining mines in the Mysore goldfield. During 1907 the ore milled was 124,160 long tons, yielding 64,084 bullion ounces. In addition 9068 oz. was obtained by cyaniding 89,164 tons of tailing, and 410 oz. recovered in dismantling one of the old mills. The total production therefore was 73,562 oz., which realized £278,898. It will be seen that the average yield is only just over 12 dwt., as compared with just under 18 dwt. at the Nundydroog, details of which I gave last week. The profit on the year's working was £94,454, out of which over £50,000 has been written off for depreciation, etc., leaving a disposable amount of £$40,922. Out of this dividends of 17½% on the preference and 7½% on the ordinary shares have been paid. In writing of the Mysore Gold Mining Co. a fortnight ago, I mentioned that in future John Taylor & Sons' companies had decided to pay for all new improvements out of revenue, instead of issuing new shares. The cause of this new policy is very definitely seen by examining the result of the issue of shares in the Ooregum company made last May. Out of 137,000 new shares then offered only 38,544 were taken up.

As I mentioned in a recent issue, the orebodies at the Oroya Brownhill mine, in West Australia, are showing signs of rapid exhaustion, but there is enough left to last during the current year. During 1907 the tonnage treated was 133,395 short tons, and the gold won was 102,302 fine ounces. The working costs, exclusive of development, depreciation, and office expenses, were 19s. 8½d. The profit was £259,775, and £267,187 was distributed as dividends. Active prospecting in several parts of the mine has been and is still being conducted, and it is hoped that further deposits may be discovered.

JOHANNESBURG, TRANSVAAL.

Negotiating for Malagasy Labor.—Illicit Liquor Traffic.—Bonanza Mine Closed.—Miner's Anaemia in Rand Mines.—Brakpan Shaft Cuts Reef.—New Method of Shaft Plumbing.—Gordon Drill in Practice.—Proposed Amalgamation of Rand Mines.

There is probably no more inconsistent government than that of the Transvaal, and during the past fortnight we have had one of the most startling examples of their inconsistency. As is well known, the Het Volk party, like the Liberal party in Great Britain, climbed into power on the Chinese labor question. In the eyes of the Boer party, one of the greatest crimes was that of introducing Chinese on the Rand for working the mines. For some time past there have been rumors that the Government of the Transvaal has been negotiating with the French Government for labor from Madagascar. Why the Malagasy laborers of Madagascar (which would prove inferior to coolie labor) should be allowed on the Rand and the Chinese forbidden to come, is a problem which none save the politicians of the Boer party have been able to fathom. The French Government will no doubt refuse to allow Malagasy labor to come to the Rand and nothing will result from the incident, but it is a good example of the inconsistency of the present Government.

At the moment there is sufficient Kaffir labor for the Rand mines, but in looking forward there are signs of scarcity, especially if pronounced prosperity should return to South Africa. It is to be hoped that when the Government finds itself at a loss to procure sufficient labor it will admit the error of its ways and allow the most satisfactory we have yet had, namely, the Chinese, to return to the Rand.

On account of the continued depression and the increased

number of Kaffirs at work, there has been a large increase of late in the illicit liquor traffic. The Kaffirs, especially on Sundays, will pay a high price for liquor in any form, and as the temptation to a man or woman out of employment, with no chance of finding work, is very great, many of these people go in for selling liquor illicitly to natives. As long as they are not caught, the rewards for being in this trade are enticing, but when the law gets hold of the illicit liquor dealer he has a hard time. After the offense has been proved, which is at times a difficult matter, the culprit is condemned to prison at hard labor for periods of six months to two years. No fine can be paid for this offense, as the law requires imprisonment. On account of a large number of convictions for illicit liquor dealing, some of the Government orators have lately been defending their 'beer bill.' By this bill it would have been possible to supply natives with liquor, had the bill become a law. The argument of Het Volk is that it would be better for the natives to be supplied with liquor under Government control than to buy the vile stuff which the illicit liquor dealers supply to the Kaffirs. The opposition (namely, the Progressive party) takes an entirely different view of the question, and is pledged to the principle of total prohibition of liquor to natives. On the whole, the people of the

Traveling in Rhodesia.

country are inclined to agree with the Progressive party on this point.

The Bonanza mine has died at last. After running two or three years longer than the official 'life,' the concern has ceased to produce gold. But the reduction plant is as active as ever, for the Robinson Central Deep, an adjoining mine, has taken over the mill. This gives the Robinson Central Deep an additional 50 heavy stamps, besides the 100 stamps now at work elsewhere. Before a commission now sitting in Johannesburg important evidence was given last week by one of the medical authorities of the Rand, on the subject of ankylastomiasis (miner's anaemia). On account of the acid water in the mines, and the dry climate, this disease has not spread as rapidly as it would in a wet country, or in mines where the water was alkaline. Nevertheless it is bad enough, and the mine doctors have been warned to look out for it. Some of the Kaffirs arriving on the Rand from Central and East Africa suffered greatly from this disease. From 60 to 70% of the new men are sometimes affected. The white men in the mines catch the disease through lack of care. On account of the information supplied, and the precautions taken, ankylastomiasis has not so far attacked a large number of the under-ground workers on the Rand.

At the Brakpan mine the reef was cut on September 30 by shaft No. 1, at a depth of 3096 ft. The ore at the point of intersection assayed only 2 dwt. across 2 ft. of vein, but later development revealed 9 dwt. ore 60 ft. away, and 120 ft. from the shaft the value had risen to 31 dwt. across 24½ in. of vein. It is thus seen how irregular is the distribution of gold in the Rand deep mines. In connecting the surface and under-ground surveys at this mine a new method of shaft-plumbing was employed, which is correct to within one minute at a depth of over 3000 ft. This system of shaft-plumbing was devised by Frank Roberts, manager of the Knight's Central mine. Despite the success of the Gordon drill in the recent competition, it is not proving so successful in actual practice. Its defect consists in the necessity for turning the drill by hand, imposing a duty upon the workman to which the inattentive Kaffir is unequal.

Some very sarcastic letters have appeared in the press lately regarding the huge amalgamation schemes that have been suggested. The proposed East Rand Proprietary amalgamation has brought out the most opposition. As is well known, the 'outcrop' companies of this group, such as the Angelo, Dreifontein, Cason, and New Comet mines, are as good as any on the Rand. The grade of ore is satisfactory, they are all profit earners and dividend payers. But with the deep-level companies it is different. Take the Angelo Deep for instance. They have developed 831,936 tons of a value of 3.55 dwt. and 889,575 tons of a value of 3.97 dwt. From this huge tonnage 13s. per ton could be extracted, and with present day working costs this is useless. The outlook for the rest of the deep-level ground is not much better. There has been a distinct impoverishment with depth. It is now proposed to combine all these mines, both 'outcrops' and 'deep-levels,' into one huge concern, to be known as the East Rand Proprietary Mines. For the shareholders of the deep levels, whose ground is of little value, this scheme is satisfactory, but it is distinctly unfair for the people who have bought the 'outcrop' shares on the basis of a 5 to 6% return on their money. It would have paid them better to have bought Consols in the first place. Several correspondents in the local press have pointed out that this amalgamation will be rushed through before the shareholders in Europe and elsewhere have had sufficient time to realize the significance of the proposals. From a mining standpoint a large area with big stamping plants is desirable, and the Rand should have been started off in this way. It is rather late, say the correspondents, now that the rich 'outcrop' companies are half worked out, to come forward with such propositions. Let the 'deep-level' claims be amalgamated into huge mines, but don't try to ruin the shareholders of the 'outcrop' companies by putting them into the deep-levels. To do so is sheer stock exchange jugglery, and will bring the Transvaal into worse repute than at present.

Another problem which has agitated the community more than usual is that of the unemployed and destitute. So intense has the suffering become that public meetings have been called to save many of the people from starvation. At such a time people are liable to become emotional and let their hearts run away with their heads. As State Secretary Smuts said at a mass meeting called to consider the problem, the question of the unemployed in the Transvaal is more difficult than in most other parts of the world. The Rand has more or less spoiled the white men for hard labor. Unless he is given an impossible wage the white man will not do manual toil for any long period. The standard of living has been set so high that the workingman has forgotten the virtue of frugality. Smut's statement of the Government's experience in railroad construction well illustrates the difficulty of getting the white man to work in this country. In the construction of a section of a railroad only white men were employed, at a wage of 6s. per day, which is about 2½ to 3 times as high a wage as the Kaffir is paid. The white men did not remain long at this work, and the experiment was put down as a failure. The Government is not discouraged, for it is its fixed policy to extend the use of white labor. They are offering to take on white men for further road construction at 4s. per day, but for this offer they are being greatly abused by the white people. There is a large number of unemployed, both among Dutch and British, who are fast becoming pauperized by the doles of charity that have been given them. As long as they receive enough to live on they will never work. The community is fast learning that work must be

found for the white men, and all who can work and won't work must be allowed to go under. The curse of the place as far as the unemployed white man is concerned is the Kaffir. The black man is on so much lower a scale, and is so protected by the Government, that the white man cannot hope to compete with him as an unskilled laborer. The long talked of report of the commission appointed by the Government to enquire into the question of labor for the mines has been published. If carried ont, the plan of the majority would speedily ruin the Transvaal. The gist of the report is to entirely exclude Kaffir labor from the mines, within a short period, and employ white labor only. One member handed in a minority report, in which he unmercifully ridicules the report of the majority and shows how impracticable it is. The general opinion is that the Government will scarcely notice the majority report, for they must recognize that it is academic and hypothetical. The pity of it is that so much time and money should have been wasted.

DENVER, COLORADO.

Strong Feeling in Telluride. — Activity in Upper Clear Creek. — Record Shipments at Cripple Creek. —Development Work on Republican Mountain.—High-Grade Ore in the Accident Mine.

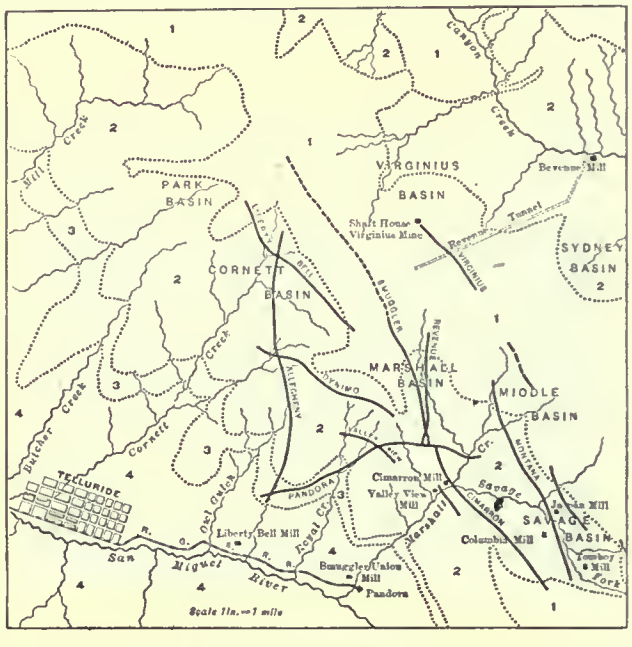
The unsuccessful attempt to murder General Bulkeley Wells at the Smuggler Union has aroused the whole San Juan district. A reward of $16,500 is offered for the capture of the person or persons implicated. The police and private detectives are working on the case, trying to determine whether it can be traced to the recent trouble with 'high-graders' in the camp, or to the coming trial of Stephen Adams for the murder of Arthur L. Collins, the former general manager of the Smuggler Union.

The Precious Metals corporation of Silverton has sold its properties on Mill creek, near Chattanooga, to J. R. Allen of New York. A small force of men has been put to work on the property. The Upper Clear Creek district becomes more active as spring advances. Several sales of mining properties are recorded, among which is the transfer of the Red Oak Mining & Milling Co.'s property near Georgetown to C. H. Poirier and associates, of St. Louis, Mo. The Becky Sharp mine in Russell gulch has been leased to Jones and Griffith, who are now carefully prospecting the property. The Queen of the West and the Robert Emmet mines in Chase gulch are being unwatered and the shafts re-timbered by Bradley Bernard and associates. George S. Dubois, the discoverer of the Lost Bullion mine near Silver City, N. M., has escaped further prosecution by the Government for using the mails to defraud. He was killed in a quarrel at Ballarat. Boulder county is rapidly becoming notorious through such transactions as those of W. W. Degge, and the Lost Bullion mine swindle.

A carload of machinery has arrived for the Arctic mill, which is now in course of construction. The erection of the electrical machinery on the Colorado Co.'s two new Bucyrus dredges on the Swan is nearly completed. Active development work has been started by the Golden Glory Tunnel Mining Co. on Saxon Mtn. The adit is now 600 ft. long, and it is expected that the Bellevue-Hudson vein will be encountered within 150 ft. On the Lebanon adit property, situated on Republican Mtn., a raise is being made on lode No. 10, which was intersected at 1000 ft. from the portal. A good orebody is being developed and occasional shipments made. Work has been resumed on the McKinley Mining & Milling Co.'s property, situated on Bard creek, Lincoln Mtn. The work is being done by contract on the McKinley adit, which is now 325 ft. long. A streak of lead ore from 12 to 18 in. wide was recently found, and this is being explored by drifts. The McKinley lies to the west, and is an extension of the Ramsdell mine, which has been steadily developed during the last two years.

Cripple Creek has established another record by producing 61,062 tons during March. The gross value was $1,385,177, which is an increase of $142,864 over the value of the February output. The United States Reduction & Refining Co. has started up its Canyon City plant in order to handle the tonnage for April, which promises to exceed that of March. The low freight and treatment charges continue, and competition between the U. S. Smelting & Refining Co. and the Golden Cycle is very keen. Operators in Cripple Creek are enjoying the unusual condition of having more miners looking for work than can be taken on. This is especially advantageons in the drainage adit work, as it makes it possible to keep the force up to a high degree of efficiency. The adit is now in 1960 feet.

Flaacks, Mullen & Co., operating on the south end of the Rigi group on Battle Mtn., and adjoining the Portland mine, are shipping a carload per week, assaying about $50 per ton. The ore is being broken at two places on the 50-ft. level between 6 and 8 ft. wide. The ore shipped out since the lessees started work three months ago varies from $25 to $90 per ton, and carries syivanite. Stoping is in progress and a winze is being sunk on ore. It is expected that development work will be started on the 100-ft. level. The shaft has been sunk to a depth of 500 ft. A 3-ft. body of ore with a narrow streak of exceptionally high grade has been found



Sketch Map of Telluride District, Colorado.

2 San Juan Formation. Andesitic Breccia. Jurassic and Cretaceous. 4 Shales and Sandstones.

in the Accident mine on the west slope of Gold hill, adjacent to the Index and Pointer mines. The find was made near the shaft on the 300-ft. level, and consists of tellurides.

The feeling against Stephen Adams and the Western Federation of Miners is intense in Telluride since the unsuccessful attempt to murder Bulkley Wells, manager of the Smuggler-Union mine. For this reason Mr. Hilton, the attorney representing Adams, has asked for a change of venue. The application is simply another excuse for delay in a matter which gets worse the longer it is fooled with. In general, the district is active, especially on Mill creek and Deep creek, where development has been in progress all winter. The Little Mary Mining Co. has leased two batteries in the old Pandora mill, and is milling all its ore there. The Calumet-Telluride Gold Mining Co. has developed a large body of ore on its property in Chapman gulch, and is making arrangements to build a mill.

The monthly pay-roll for the Cripple Creek district was the largest since 1903, and yet there is a large number of idle men in the camp. The water flowing from the El Paso tunnel is steadily decreasing. Both the Elkton and the Mary McKinney mines have been able to resume work on their lowest levels without pumping. A 60-day prospecting permit on the Night Hawk fraction has been given to Pleasants, Prevett & Simpson. This property has been idle for

the past six years. The Golden Cycle Co. has been obliged to reduce the output of its mine for the present, as the mill at Colorado City is overstocked with ore. In the meantime, development will be pushed on the lowest level.

The suit arising from the sale of the Independence mine by the late W. S. Stratton to the Venture Corporation of London has been dismissed from court on the ground of insufficient evidence. The plaintiff, J. H. T. Deever, alleged that he had been engaged by the agent of the Venture Corporation to determine whether the mine had been 'salted' before the corporation purchased it. The famous $1,000,000 suit brought by James Doyle against James Burns has been postponed by mutual agreement. U. S. District Attorney Ward has dismissed the case against John A. Porter and others, of Durango, who were charged with conspiracy against the U. S. Government in obtaining 1080 acres of coal land by fraudulent means. The case is simply dropped until further investigations can be made, when, if the evidence warrant conviction, the matter will be pushed.

Work on the Central Power Co.'s plant at Shoshone has been stopped temporarily. The 250 men employed went on a strike because the company refused to grant the scale of wages paid last fall. A contract has been let by the Gauntlet Gold Mining Co., of Idaho Springs, to G. D. Kaye, for extending the lateral from the Newhouse tunnel along the Mammoth vein 500 ft. farther, making 1500 ft. in all. This is a low-grade milling proposition. The Eastern Colorado Power Co. has begun to put its various camps in readiness for the large force of men to be employed on the power-plant project in Middle Boulder creek. The Newton mine dump is being treated in the Allan mill at Idaho Springs, and is yielding a fair profit. The Rollins mill, in Gamble gulch, near Central City, has been purchased by the Gilpin-Independence Mining Co., which is operating the Gold Flint property. Some necessary improvements are now being made.

SALT LAKE, UTAH.

United States Lead Smelter.—Report of the Bingham Consolidated.—Resumption of Operations at Various Mines.—Railroad to Alta Re-opened.

The United States lead smelter will not resume until about July 1. It will take time to construct the roasting plant, and to make alterations in the flue system. The company will begin the purchase of ore within a month. About 130 men are employed on construction.

The work of remodeling the Sunshine mill, at Sunshine, will commence soon. A slime plant similar to the one at the Consolidated Mercur is to be installed. At a special meeting last week of shareholders of the Ohio-Kentucky Mining Co. the capital stock was increased from 150,000 shares of the par value of $1. to 600,000 shares of $5. The properties of this company are at Pioche, where a vigorous campaign of development is in progress. The headquarters of the company are in Salt Lake. The annual meeting of shareholders of the May Day Mining & Milling Co. resulted in the retention of all but two of the former directors and the re-election of John Dern of Salt Lake as president. The receipts from ore sales, including $9378 at the beginning, were $161,016. Dividends amounting to $64,000 were paid, and the cash on hand April 1 was $9084. The company claims that three years' supply of ore, based on last year's production, is blocked out. The Garfield concentrating mill of the Boston Consolidated is doing splendid work. During the first week of April the extraction was 71 per cent.

The operations of the Bingham Consolidated M. & S. Co., according to an official circular, were not very profitable during 1907, having suffered a loss of $277,000. The total liabilities are stated to be $770,185. The smelter alone ran behind more than $2000 monthly. The annual report of the Utah Consolidated for 1907 has also been issued and shows net earnings of $3.93 per share, against $9.45 per share in 1906. The income account is as follows: Metal sales, $3,744,532; expenses, $227,152; net proceeds, $3,517,380; bullion, etc., receipts, total, $4,608,913; total deductions, $1,727,892; balance, $2,881,021; miscellaneous receipts, $58,049; total profits, $2,939,070; total expenses, $1,759,413; net profits, $1,179,413; previous surplus, $2,451,228; total surplus, $3,630,641; dividends, $2,100,000; final surplus, $1,530,641.

For a consideration of $40,000, the Little Beaver Mining Co. has purchased the Marguerite and other mining claims of the Vicksburg Gold & Copper M. Co., all situated in Beaver valley. The mine and mill of the Newhouse Mines & Smelters Corporation are using electric power generated from the Beaver plant of the Telluride Power Co., near Beaver City. The Scranton Mining Co., operating in Tintic, will shortly resume ore shipments, which were suspended about the first of the year.

The mill of the Columbus Con. M. Co. at Alta has been started again, operating one shift per day. The railroad owned by the Rio Grande Western, between Sandy and Wasatch, covering a distance of about 18 miles, has been leased to J. E. Jacobs, former manager of the Salt Lake & Mercur railway, who proposes to supply better transportation for the mines of Alta. The road has been out of commission for several years, and the track will have to be practically re-laid the entire distance.

TORONTO, CANADA.

Provincial Government's Mine at Cobalt.—Corrupt Practices.—Official Juggling With Mine Titles.—Dismissal of Geological Survey Editor on Erroneous Charge.

The relations of the Provincial Government of Ontario to the mining industry have been a good deal discussed lately, in connection with several matters that have come before the Legislature. The policy of the Government as regards the Provincial, or as it is generally known, the Gillies Limit mine, at Cobalt, owned and operated as a public work, has been attacked. The Government has given out very little information as to the condition and prospects of the enterprise. It is claimed that as the investing public is deeply interested in Cobalt, the fullest information should be afforded as to the value of the property, the character of the ore at different levels, and upon anything which may throw light on the general question of the permanency of Cobalt veins. About all, however, that the Department is willing to give out is data concerning the extent of the workings and the amount of ore taken out. Frank Cochrane, when pressed for further details, stated that the mine was being worked as a business enterprise, and he did not propose to furnish data which might be used to boom wildcat schemes. The estimated revenue for the current year from this mine is $100,000. Another and much more important matter which promises to be an issue in the next election contest, is the apparently interminable Cobalt lake question, a new phase of which has cropped up. The whole business throws a strong light on the subject of how mining titles are mixed up with political trickery, which may partly explain the shyness of American investors with regard to Ontario propositions. It will be remembered that the title to the bed of Cobalt lake was claimed on the ground of original discovery by the Florence Mining Co., but the claim was not recognized by the Government, on the ground that at the time of the alleged discovery the lake had been withdrawn from prospecting. The Government sold the lake to the Cobalt Lake Co. for $1,085,000, whereupon the Florence company brought action to maintain its claim. Before it came to trial the Government secured the passage of a special act validating the title of the Cobalt Lake Co. Application has been made to the Dominion Government to disallow that measure, and in the meantime legal proceedings are suspended. All this is an old story. Now comes another claimant, Harry Dreany, who asserts discovery prior to that of the Florence company, and states that his application to record the same in May, 1905, was refused, the reason assigned being that the Government had not decided on its policy regarding that territory. Dreany then came to Toronto, and gave a large interest in his claim to Frank B. Chapin and Charles

Lamarche, who asserted that by using their political influence with the Government they could have the claim recorded. Lamarche was a member of the Legislature. About that time Frank Cochrane was in search of a constituency. A deal was made; Lamarche resigned his seat, Frank Cochrane got it, and the mining recorder received official instructions to record Dreany's claim, which was done in July, 1905. Notwithstanding this, however, in the following month Cobalt lake was withdrawn from location and subsequently, as already mentioned, disposed of to the present holders, Lamarche receiving a snug office as compensation. These facts were developed in a damage suit brought by Dreany against his partners in the deal, and an attempt was made to have a full investigation before a committee of the Legislature, which, however, was avoided by the tactics of the supporters of the Government. The affair has been ventilated in the Legislature, however, and is likely to give the Government a good deal of trouble. The shareholders of the Cobalt Lake Co., whose stock has been steadily depreciating as a consequence of these continuous attacks on its title, has petitioned the Government for compensation. The title of the Temiskaming & Hudson Bay company is also assailed, the Government having brought action to recover royalty on the output on the ground of absence of valid right to the property. It is anticipated that a settlement will be effected. The transaction is not of a nature to encourage outsiders without a political pull to invest heavily in enterprises on the faith of an Ontario title, which may be subject to a 10 or 25% royalty hold-up as soon as it becomes productive.

F. J. Nicolas, editor of the reports and publications of the Canadian Geological Survey, has been dismissed on the unwarranted accusation of having written or inspired the criticism on J. W. W. Spencer's report on Niagara Falls which appeared in the MINING AND SCIENTIFIC PRESS. Samuel Graves, of the Mines Branch, has been appointed his successor. A. C. Boyce, of Algoma West, drew the attention of the Canadian Parliament to the subject.

BUTTE, MONTANA.

Amalgamated Co.'s Production.—Reduction of Cost.—Butte-Milwaukee Resuming.—Decision Adverse to Placer Ground Titles.—North Butte Extension.—Rumors of Consolidation.

The Amalgamated Copper Co. is not returning to normal conditions of mining and copper production as rapidly as had been promised at the time of resumption on the first of March. Not more than 3000 additional men have been put to work in the Butte district since March 1, making the total number employed at the properties of the Amalgamated subsidiary companies between 5000 and 5500. The number employed normally is about 8000. The Amalgamated companies are producing copper at the rate of 14,000,000 to 16,000,000 lb. per month, and it is not considered likely that the production will be very much increased for some time with copper prices declining. The fear is general in Butte that if the copper market does not improve within the next three months, another shut-down of the Butte mines will result. Still it is asserted by high officials in the Amalgamated company that the latter can produce copper as long and as cheaply as any other important concern can do so and make money. It is a fact, demonstrated since the resumption of mining, that the Amalgamated can produce copper much more cheaply than it did at any time during the past seven years, and that the present production is not costing over 10c. per lb., including refining and selling.

Orders have been received from New York by John Miles, superintendent for the Butte-Milwaukee Mining Co., to prepare for resumption of development work, and a foundation is being built to receive the new Nordberg hoisting engine, which has been shipped and will be in Butte by the time the foundation is ready to receive it. When the new machinery is installed sinking will be resumed on the Colonel Sellers shaft. The shaft is now down 700 ft., and it is the intention of the company to sink it to a depth of 1500 ft. before doing any exploration work. It is the opinion of mining engineers and operators familiar with that part of the Butte district that good commercial ore will be found in the veins at that depth. The Butte-Milwaukee group of claims is well situated in the part of the Butte district where the biggest strikes of ore have been made in recent years.

In another action similar to the one decided a week ago by Judge Hunt of the United States Court, involving a contest between quartz and placer claimants in South Butte, the Supreme Court of Montana has given a decision in favor of the quartz owner, thus going contrary to the decision of Judge Hunt. However, both decisions are based entirely on facts, and not on legal questions. In the Hunt decision it was held that the proof of the quartz claimants was not strong enough to support a judgment in their favor. In the State Supreme Court, in an action of W. A. Clark and others against J. A. Clifford, the Court holds that the evidence was sufficient to show that valuable quartz leads were known to exist at the time application was made for the placer patent. The entire southern portion of the Butte district is covered by placer patents, but it was well known to old-timers that copper veins existed before the placer patents were applied for. The recent decisions indicate that it is only a question of proof, and that if the locators of quartz claims can marshal sufficient evidence to satisfy courts and juries that quartz veins were known to exist before placer patents issued, the quartz titles will be upheld in spite of the placer patents that have existed for a quarter of a century and more. The Amalgamated Copper Co. owns a great deal of ground under both placer and quartz titles, as does the East Butte Co. The latter owns a large quartz location, known as the Oneida, under which it has not yet asserted rights beyond its placer ground. If it does so, and makes good its quartz title in the courts, its mineral rights will be immensely extended. Its title will be questioned for the first time in a small suit brought by the South Butte Mining Co. against some lessees working in East Butte ground, whom the East Butte company is protecting.

The North Butte Extension M. Co. has resumed sinking on its shaft, which was 525 ft. deep when work was stopped, while a large station was being cut on the 500-ft. level. The station has been completed, and a big pump is being installed. In the meantime sinking will be carried on in addition to other work. A 3-ft. seam of well mineralized material was cut in the station. The ground of the company, wherever opened, is found to be highly mineralized. Several veins and numerous seams have been cut in the shaft and stations. It is probable that some cross-cutting will be done at the 700-ft. level.

The mines of the Butte district are running and producing copper at about the same rate they did during the latter part of March, and it is the intention of the Amalgamated company to keep production down to a conservative volume. About 8000 tons of ore are being shipped daily to the Washoe smelter.

A persistent rumor is afloat that negotiations have been on for some time for the acquisition of the properties of W. A. Clark in the Butte district by the Amalgamated interests. The rumor has once been denied by Mr. Clark, but in the face of that some of his close business associates have acknowledged that there is some truth in the rumors. They point to the fact that some important business plans of Mr. Clark have been held up for months, something unknown heretofore in Mr. Clark's business matters, which is believed to be due to the pendency of negotiations for a transfer of all his business interests in Butte. Reports have it that his bank alone is exempt from the proposed deal. Several years ago Mr. Clark received a flat offer for his mining interests in Butte, but he declined because he considered the price at that time, when the copper boom was at its height, inadequate. Conditions have greatly changed since then, and friends of Mr. Clark say that he is not averse to retiring from the activities of mining, as he is getting well along in years.

COBALT, ONTARIO.

Increase in Shipments.—Milling Facilities.—New Discovery of Rich Ore.—Mining Under the Lake.

In the first quarter of 1908 the shipments of ore from Cobalt have amounted to 4332.48 tons. Five new shippers have made their appearance during this period, namely, the Casey, Cobalt Lake, Crown Reserve, Provincial, and Silver Cliff. These are expected to prove regular shippers; but as the Casey does not lie within the limits of the camp, predictions concerning it cannot be made. It lies about 12 miles distant. Twenty-five mines shipped ore during the first three months of 1908. These were: La Rose 751 tons, O'Brien, 714; Nipissing, 410; McKinley-Darragh, 379; Silver Queen, 240; Tretheway, 213; Buffalo, 205; Coniagas, 192; Temiskaming & Hudson Bay, 192; Kerr Lake (Jacobs), 135; Watts (of King Edward group), 121; Temiskaming, 119; City of Cobalt, 114; Cobalt Lake, 90; Nancy Helen, 71; Foster, 54; Drummond, 46; Cobalt-Central, 45; Town-Site, 43; Silver Leaf, 31; Right-of-Way, 30; Silver Cliff, 26; Provincial, 25; Casey, 20; Crown Reserve, 7; and a miscellaneous shipment sent for smelter experiments, 20 tons. In the corresponding quarter of 1907, nineteen mines shipped 2911.41 tons. The market for Cobalt ores is extending. The smelters at Denver, Colo., and at Trail, B. C., got the La Rose and City of Cobalt ores respectively, and the Nancy Helen shipped 40 tons to Trail the previous week. The Perth Amboy, Carnegie, and Chrome smelters each got a car, and the Cobalt Lake Co. shipped to Swansea, Wales. The Kerr Lake Co. or Jacobs has signed a contract for 100 tons with a German smelter in Hamburg, and sent its first carload last week. Then a third Canadian smelter is in operation and received its first car from the Coniagas mine last week. This smelter is situated at Thorold, in Welland county, only a few miles from Niagara Falls. The shipment last week was the first trial of a car lot, and consisted of high-grade ore and concentrates. The Coniagas was one of the first mines to install a concentrating plant. Superintendent Reddington has his mill in operation and treats 50 tons of ore daily, 1500 lb. of concentrate being the resultant product. This mine will hereafter ship but two carloads per month, or about 1¼ carloads of high-grade ore and ¾ carload of concentrate. The Cobalt-Central mine, known as the 'Big Pete,' also ships only high-grade ore and concentrates, and the Buffalo and McKinley will no longer ship their low-grade ores. Two custom concentrators will be in operation within a couple of months. The net result will be the absence of shipments from Cobalt of ore carrying less than 500 oz. silver per ton.

The sensational discovery of a rich ore-shoot on the shore of Kerr lake on an extension of the Silver Leaf vein has revealed as rich a vein as any found in the camp. The Crown Reserve paid the Ontario Government over $175,000 for the right to mine 22 acres under Kerr lake. In addition to the purchase price, the Government receives a royalty of 10% on the ore mined. The Silver Leaf is one of the properties bordering on the lake, and this company made a rich find last fall near the lake. An open-cut was started about 21 ft. square. There was vein matter throughout the entire width, and solid metal from 4 to 7 in. wide was found. There were also innumerable calcite stringers carrying silver in varying quantities. This open-cut is now a shaft nearly 110 ft. deep, and at a depth of 100 ft. the vein is 14 in. wide, consisting of a mass of calcite and silver. The richest part of the ore-shoot has a length of 7 ft. Recently a piece of vein-matter was broken which weighed 20 lb. and was practically solid silver. A drift has been started in the Leaf shaft, at a depth of 80 ft., under rich ore. A few feet distant, just across the boundary line, the Crown Reserve started an open-cut. This is now 40 ft. deep, 25 ft. long, and 8 ft. wide. At the bottom of the cut the vein is 28 in. wide, composed entirely of calcite and silver. A piece of the vein-matter was hoisted the other day weighing 1200 lb., that yielded at the rate of 10,000 oz. silver per ton. The Crown Reserve shipped 6.85 tons of ore by express to the Perth Amboy smelter, that the superintendent, Sam Cohen, affirms will net the company over $35,000. A 20-ton car of this high-grade ore will be shipped next week. The ore has to be cut up with chisels, being so rich in silver.

John MacDonald, superintendent at the Foster mine, has been pushing development work and will resume shipments this month. The main shaft is down 225 ft., and a station is now being cut preparatory to driving the third level at a depth of 210 ft. Sixty men are employed in this mine, with six drills, running double shift. The Cobalt Lake mine is now a regular shipper. Two shifts are maintained at work, 65 men being employed. Shaft No. 4 is sunk on the shore line near the Nipissing tunnel. The first level is at a depth of 86 ft., and the second level at a depth of 150 ft. From the first level a drift was run on a calcite vein extending under the lake, and some stoping was done. This vein averages 200 oz. silver per ton. Ninety-three feet of cross-cutting was done toward the north, at which point the big niccolite vein (No. 3) was tapped. This vein has a width of 28 in. and is rich in cobalt. The cross-cut from the shaft has been extended beyond No. 3 vein 190 ft. and will be continued under the east shore of the lake to tap all the veins on that side. There is also a cross-cut from the drift extended from shaft No. 4, connecting shafts 4 and 5. This cross-cut continues past shaft No. 5 in a southerly direction 215 ft. At the 150-ft. level a drift has been run from shaft No. 4 110 ft., which will be continued across the lake. Shaft No. 6, near the McKinley-Darragh, is now down 135 ft. Driving on the first level will be started this week. Fifty feet of rock will be left between the drifts and the bed of the lake to ensure safety. E. L. Fraleck, the superintendent, has encountered no difficulties in mining under the lake which could not be successfully overcome.

At the Right-of-Way the superintendent, Joe Houston, has eight men and six drills working on double shift. Shafts No. 1 and 2, which are 520 ft. apart, were connected by a drift on the 86-ft. level.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

In electrolytic refining, the anodes cast from blister copper are dissolved and the pure metal deposited on the cathode, the precious metals being left as an insoluble slime.

Fine grinding cannot be economically accomplished in stamp-mills, and even when a large proportion of the pulp is highly comminuted, the product will show a wide variation in size. The expenditure of power increases rapidly with the degree of fineness attained. To accomplish fine crushing in a stamp-battery it is necessary to use a deep mortar, to increase the height of drop of the stamps, and to decrease the speed.

In experiments made on the smelting of iron ore by electricity, the amount of carbon used has generally been too high to get the best efficiency, theoretically. A smaller proportion of carbon, more perfectly consumed to CO_2, would generate more heat, and thus help the furnace. In most of the work the electric current furnished about two-thirds of the energy required for all purposes and the carbon one-third. Gas analyses are of the utmost importance in regulating the efficient working of the furnace.

Hard amalgam can be removed from old copper plates by covering the plate with a wooden frame, well packed with blankets or burlaps, so arranged as to leave a space of several inches between the plate and the frame. Into this space turn dry steam at as high a pressure as possible. After steaming for several hours, remove the frame, and if feasible chill with cold water. The hardened amalgam will, to a considerable extent, become detached in flakes, or may be readily removed with scrapers. In the hands of careful workmen the amalgam may be removed completely with chisels or scrapers after steaming, without injury to the surface of the copper plate.

The cost of mining narrow veins depends upon the method used. In the case of a mine in Rhodesia two systems were tried, that of mining the quartz and adjoining rock together, and later resuing was applied, that is, stripping the vein first on the foot-wall to a depth of 30 in. This waste rock was largely used as filling, although a certain percentage was necessarily sent to the surface. When about 3600 sq. ft. of quartz had been stripped, this was broken down as a clean product, so that no sorting was required. In both cases the gold occurred in a 6-in. streak of quartz assaying about 50 dwt. per ton. Of this, 75% was recovered, that is, $36 per ton. In the former case the cost of mining and milling 100 tons was $772, representing a loss on the operations, while by adopting the stripping method, a good profit was obtained. In another case, a 12-in. vein assaying $28.80 per ton was mined by a similar method, and a marked reduction of costs effected.

Preservation of timber against decay is effected by impregnation with various substances, among which are blue vitriol (blue-stone or copper sulphate), corrosive sublimate (mercurie chloride), zinc chloride, and chiefly creosote oil derived from the distillation of coal in gas-making and in by-product coking. The creosote oil is contained in the tar condensed from the hot gases leaving the retort. It is separated from the tar by distillation between the temperatures 400 and 700°F. The European output of creosote oil is obtained by distillation at a slightly higher temperature, the resultant oil being less soluble in water and less subject to evaporation in the air. On these accounts it is superior as a wood-preservative. The United States Government is advocating the production in this country of creosote oil of better grade for preservation of timber, as an additional means for protection of the rapidly disappearing forests, by lessening the consumption. Bulletins on this subject may be obtained gratis from the Forest Service of the Department of Agriculture at Washington.

In a case where 'A' owns two adjoining claims, and in December, 1906, performed $100 worth of work, and in January, 1907, another $100 worth, the work being performed on but one claim, though benefiting both; and again in December, 1907, 'A' performed $50 worth of work, and in January, 1908, another like amount on the same claim; after which 'B' jumped both claims: whose claim is valid?

'A' may plausibly claim the $100 worth of work done in January, 1907, the $50 in December, 1907, and the $50 in January, 1908, aggregating $200, as work done for the year 1907 for the benefit of the two claims. In other words, in 1907 he expended $150 and in January, 1908, before any adverse re-location was made, he resumed work and made up the deficiency, that is, $50. A subsequent locator would not, we think, have any standing in court which would permit him to go back of January, 1907, and show a pending delinquency for 1906, as at that time the re-locator had no interest in the claim. The subsequent re-location could not by operation of law relate back to 1907, so as to permit an inquiry into the status of the claim at that time. A's defense against a re-location made after January, 1908, would be complete as showing the $150 expenditure at any time in 1907, and the $50 in January, prior to a re-location. This view, if it is correct, enables owners of claims to overlap the assessment work and to a degree hold claims without really performing the full amount of work each year. But the performance of assessment work is not a matter with which the Government is concerned. Failure to perform it can only be taken advantage of by a hostile re-locator, and the facts and conditions as they exist at the time of the re-location are the only ones which are the proper subjects of inquiry. While 'A' has in a measure evaded the law, the subsequent re-locator is not in a position to complain. While the solution offered is involved in some doubt, we incline to the view that the re-locations are invalid and A's title will prevail against them.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Smelting Zinc Electrically.

The Editor:

Sir—In your issue of March 7, under the heading 'Concentrates,' you say: "Zinc smelting by electricity is now being carried on successfully in Europe and British Columbia." Mine operators in the Slocan, B. C., are vitally interested in a successful electric process for the reduction of zinc and lead ores, and would greatly appreciate a full description of the European process mentioned in your columns. Your statement as regards British Columbia is a little misleading. A small experimental electric plant was started at Vancouver two or three years ago and was reported a success. The same company began the erection of a smelter of commercial size at Nelson last year, but owing to lack of funds the plant has not been completed. In the *Transactions* of the Tristate Mining Association (and in your issue of December 7, 1907), Frederick T. Snyder describes this process and says a complete separation of both zinc and lead was made at a greatly reduced cost over that of the ordinary retort type of furnace. The commercial success of such a process means much, not only to the Slocan mine but to other properties all over British Columbia and the Coeur d'Alene in Idaho as well.

The orebodies of this immediate neighborhood are veins of argentiferous galena and sphalerite, with some tetrahedrite, chalcopyrite, and pyrite, in a gangue of quartz, calcite, and some siderite. They cut through limestone, shale, and slate, and occasionally granite, diorite, and diabase are encountered. Near the surface galena predominates, but at depth nearly every mine in the district becomes 'zinky' and work is then abandoned. This is well illustrated in the Standard mine, situated at an altitude of 1700 ft. above Lake Slocan. The old stopes in the upper levels show some zinc-blende, but the ore shipped was a high-grade clean galena. In the present workings, between tunnels No. 3 and 4, the ore is a clean argentiferous galena, the shipping ore running 65% lead, and very little of it reaches the 'zinc penalty limit' of 8%, above which point the Trail smelter penalizes zinc at the rate of 10c. per unit. Tunnels No. 5 and 6 have not as yet encountered the main ore-shoot, but the Emily Edith mine, adjoining, and at a much lower horizon on the same vein (800 ft. above the lake), has but little lead and large bodies of zinc ore. A sample in the main orebody, for example, shows: 24.6% Zn, 10% Pb, 10.3 oz. Ag. The commission appointed to report on the zinc resources of British Columbia advise a very complicated and costly process for treating such an ore, involving as it does water concentration, roasting, magnetic separation, and finally the smelting of the separate products.

The Emily Edith Mines Co. Ltd., an English corporation, failed to make their mine pay, and after doing a lot of prospecting in an endeavor to find clean galena, ceased operations and leased the property. The lessees shipped several carloads of zinc concentrate to the zinc smelter at Frank, Alberta, but when that plant shut down everything came to a standstill. The Sullivan mine and smelter at Marysville, B. C., closed down, it is said finally, about the first of March for much the same reason, namely, ore getting too zinky. Everyone damns zinc, whereas it should be a valuable asset.

There are several promising looking prospects on Pine creek, near Wardner, Idaho, in which the ore is a compound of galena and sphalerite so intimately associated that extremely fine grinding would be necessary before a separation could be made either by a water or magnetic concentrator. This would produce so much slime and involve such a high loss in the tailing that separation is altogether impracticable. The only solution appears to be: Separate out the gangue by means of jigs, tables, vanners, etc., and smelt the mixed concentrate of lead, zinc, and iron together, separating the lead from the zinc by liquation in the furnace.

An electric smelter that could do this would indeed be a blessing, especially as we have almost unlimited water-power in the Northwest, wherewith to make the wheels of a generator go round.

J. V. RICHARDS.

New Denver, B. C., March 15.

Producer-Gas Power.

The Editor:

Sir—Mining involves the moving of masses; and for this, power is requisite. It is an odd phase of our slow and tardy grasp of evolution that power or energy is the one common object of strife in this comedy-tragedy called natural selection. New houses, new clothes, food, fuel, money, new materials, all represent only so many kinds of matter in a high state of energy; and old clothes, old houses, ashes, waste, and debts represent matter in their low state of energy.

These truisms are as stupid as they are melancholy, unless someone has some remedy to suggest; and I can imagine some tired superintendent at night looking critically over this column to see if it offers him any help in his unequal struggle with ore-getting and ore-dressing. It is almost an axiom that nowhere can a manufacturer make more money with less lost-motion than by saving on the power end; and if any reduction of fixed power-charge can be made anywhere it ought to be made in legitimate mining. The proposition that I wish to emphasize refers to the use of the gas-producer as a source of power for the mine as well as for the mill: and the miner whom I have particularly in mind is he of the intermediate grade who has outgrown the mule power and who must have a small engine, this year 10 or 20 horse-power, next year 30 or 40 hp., and so on. For such business conditions the use of producer-gas power is a proposition to be considered. Probably most of the readers of the MINING AND SCIENTIFIC PRESS are familiar, in a general way, with this subject, but it is not probable that many can have taken time to study the gas-producer and the

gas-engine thoroughly as applied to their own needs. This is the more strange because the miner is usually a progressive man, progressive both by instinct and by necessity. The condition could be explained more easily if it were in New England, where I have been working for nearly a year to introduce a good gas-producer and gas-engine and where after a year's hard work they are only beginning to 'sit up and take notice.' Probably the first objection that will be raised against the gas-producer is the question of reliability, and on this point I wish to go on record: that, while there are producers and produeers, and gas-engines and gas-engines, yet, with a good gas-producer and a good gas-engine adapted to each other, a gas-power plant may be fully as reliable as a steam-power plant of the same size, provided that the gas-producer and gas-engine be made of good material, and provided that the operator is as familiar with the theory and practice of the produeer and gas-engine as he is with that of the steam-engine. Thus it is foolish to construct a gas-produeer of east-iron; and it is foolish to design a gas-engine of the vertical type with over-hanging valves: and it is foolish to put either or both of these in charge of a man who will not give them a little intelligent sympathetic attention. It is probable that most of the misunderstandings and misrepresentations that have occurred could be explained by attention to these points. Further, a complete produeer-gas power-plant costs more than a steam-plant of the same size; this is true up to 400 or 500 hp., but the saving in fuel will usually pay for the difference in 5 or 10 years, and sometimes in 3 to 5 years. And regarding the nature of the fuel—this is a large subject. Few parts of the country can depend on anthracite, the practice of which with produeers is more nearly perfect than for any other type of fuel, unless it be coke or charcoal. Bituminous coal and lignite produeers are a little more costly to build, and a little more expensive in attendance; moreover it is still an open question, whether the best practice will scrub out the tar or will burn it out.

In the East the use of peat is too far removed from commercial practicability to be regarded seriously, though peat is quite likely to figure more prominently in five or ten years; but there are other fuels, such as the ubiquitous sage-brush, which has been suggested as a produeer fuel, and which Mr. Edgar Rickard of the PRESS assured me that he had used most successfully, in lack of other available fuel, under the boiler. Of course we all know of the reports on the use of produeers at mines the world over, and some of these reports are favorable and some are unfavorable. But it is safe to say that the progressive mine superintendent should lose no time in getting acquainted with the main principles of the produeer; and if he happens to be surrounded by an abundance of available material, like sage-brush, but which is not supposed to be suitable for the produeer, there is no law of Nature which can prevent him from finding out a thing or two for himself. In remote mining camps, with good ore but no water-power, where coal or oil become too costly after distant transportation, and where gasoline is frequently used even at extravagant cost, in such places there is a chance for the enterprising engineer to do a little experimenting with fuels for the produeer. Meanwhile it remains true that all plants using power on costly coal should certainly investigate produeer gas. I shall hope, sir, to continue this subject in later communications.

Boston, March 21.

Slime-Filters.

The Editor:

Sir—Reading Mr. Arthur DeW. Foote's nutritious article in your issue of February 1, impels me to pick out the subject of slime-filters and the associated patent litigation, over which we have been holding our breath, and suggest a point that seems not far from the surface. As I am installing one of the processes mentioned, it has a practical value to me.

It may be better business, as Mr. Foote suggests, for the slime-filter process owner to speak gently and with soft words coax the frightened miner to use his process, but it seems better business to get the mining world talking of the various processes; and how can free advertising be better obtained than by a fight, on paper. An American loves a fight, and many a busy man has stopped his rush through the street to see whether the under or upper dog won. Although a prospective user of one style of filter, I am burning the best obtainable grade of the best advertised oil to learn how much better and how much cheaper I could have filtered my slime if I had bought So & So's filter. I think the black-typed advertisements eminently proper and suitable from the point of view of the advertiser. I have not read any of the patents. I never did finish reading all the patents for the cyanide process.

Let me congratulate you on the new dress for your editorial and reading columns. Busy men read at night, and fine print is trying.

Rock Penetration by Air.

The Editor:

Sir—Some years ago I had occasion to do some development work on a property where the air-compressor was run by water-power, and during the low-water season there was not sufficient power to furnish air for one drill. The vein, a very irregular one, was in quartzite, close to a syenite and quartzite contact, and in places irregular wedges of this syenite penetrated the quartzite and would cut off the vein, which would be found again on the other side of these intrusive wedges of syenite. At one point, to determine whether or not it was a persistant contact or only a wedge, a drift was run into the solid syenite foot-wall for a distance of about 150 ft. This was at a point some 1300 ft. from the mouth of the adit, and some 600 ft. from the surface, measured vertically, and this drift for the entire distance appeared to be without a fracture in the rock and, in fact, appeared as one solid block of granite.

Under the conditions as stated, I thought it would be practical to place a concrete dam about 50 ft.

back from the tunnel in the drift and then use the remaining 100 ft. of the drift for a receiver in which to store compressed air. The sides, top, and bottom of the drift were carefully trimmed, to remove all loose rock, and a concrete dam was built in the drift; in this dam a large pipe was inserted, both for a man-hole and for pipe connections; after the concrete had set the compressed air was diverted to the supposed receiver; though the dam was well rammed yet the air leaked through it very rapidly. We then turned off the air, removed the man-hole, and placed a coat of neat cement on the inside of the dam, and for 5 ft. back on the top, bottom, and sides of the drift; after this set we again turned in the compressed air, and, as far as could be determined, not a particle of air leaked through the dam. We could readily raise the air-pressure in this rock receiver to a gauge-pressure of about 45 lb., above which point it would increase very slowly. With the small plant it was impossible to obtain a gauge-pressure of 50 pounds.

Upon the closing of the intake valve the pressure would gradually decrease, and in about 36 hours time the gauge would again register at zero.

Wallace, Idaho, March 23.

Misleading Assay Statements.

The Editor:

Sir—The so-called Vidler tunnel was incorporated about seven years ago, and was planned to connect the Argentine district, on the east slope of the main range, with the Horseshoe on the west; it will have a probable length of 7000 ft., of which practically 3000 is driven on the east side and 2000 on the west. It was intended to intersect the numerous known veins of these two districts and ultimately to be enlarged so that it could be used for transportation purposes. While tunnel schemes as such have heretofore uniformly proved failures, we are all looking forward with interest to the time when this statement will be disproved and a successful tunnel for general mine exploitation be made. My object in writing is not to offer criticism of the project, but to call attention to the means whereby the promoter was enabled to raise funds for the work. Several veins were cut and drifts upon them showed that they had some ore; it was found necessary to have some outside opinion on the scheme and on the value of the ores found. To render this opinion, a newspaper man was employed; he is a man equally well equipped to write a census report, an irrigation report, or to inform the ignorant of the value of the sugar beet; his opinion of a mine is apt to be of as much value to an investing public as his opinion of a sugar-mill, and no more. It is stated that he took four general samples, which yielded the following returns by assay:

"Stope, north drift—Gold, trace; silver, 3.80 oz. per ton; lead, 15.45%; copper, trace; zinc, 4.93%; value per ton, $19.68.

"Stope, north drift—Gold, trace; silver, 7.40 oz. per ton; lead, 58.65%; zinc, 11.82%; value per ton, $63.40.

"Breast, west fork, south drift—Gold, trace; silver, 1.88 oz. per ton; lead, 4.63%; zinc, 28.07%; value per ton, $32.95.

"Breast, east fork, south drift—Gold, trace; silver, 1.12 oz. per ton; lead, 1.40%; zinc, 16.35%; value per ton, $18.18."

Sample 1.

Smelter pays 95% N. Y. quotation on the silver.
Assume: Silver @ 60c. per oz.
Lead @ $6 per 100 lb.
Zinc @ $6 per 100 lb.

Value of silver		$2.16
" " lead, 15.45%		8.80
		$10.96
On neutral basis:		
Smelting charge	$4.00	
Freight	2.50	6.50
Balance for mining and profit		$4.46

Sample 2.

Silver		$4.22
Lead, 74c. per unit for 58.65%		43.10
		47.32
Zinc penalty	$0.91	
Treatment	1.00	1.91
		$45.41

Sample 3.

Silver	1.88 oz.	Worth nil.
Lead	4.63%	No payment by smelter.
Zinc	28.00%	Not a shipping zinc ore.

If it is milled, not over 50% can be saved, that is, 14% Zn. Smelters pay $22.50 at Pueblo for a 45% Zn, at 3 tons into 1. The ore may be assumed to be worth $7.50 per ton, from which freight to Pueblo is to be deducted, say $2.50, or $5 net.

Sample 4.

Silver	1.12 oz.	Worthless
Lead	1.4%	
Zinc	16.3%	

The values given in the report as representing the various metals is so wholly misleading as to closely approximate the criminal: they are based upon the current market quotations for the metals and assume that the assay-contents will be paid for; in case the ore is shipped to a smelter there will be the various deductions, penalties, and smelting charges; in case the ore is milled, there is a loss in treatment. These are disregarded. If this work had been entrusted to a competent engineer, it is safe to assume that the bare figures submitted would be discussed as to charges or losses, so that an intelligent idea of the result to the operators would have been given. The man that submitted the report was either ignorant or suborned, in either case being wholly unfit to write a mining report. This brings up the question, should an assayer undertake to give the coin value of the metals contained in a sample without some reference being made to the inevitable deductions or losses that attach themselves to such ores? This is only one of many such instances occurring under my observation, and it is a blunder that hurts the dear confiding public. It has all the ear-marks of a confidence game wherein the respectability of the assayer is traded upon.

We cannot stop incompetents from writing reports, but can we not get the assayers of this country to adopt some form of returns that will warn the unwary and prevent the issuance of such misleading statements?

ENGINEER.

Boston, March 20.

A TERTIARY RIVER CHANNEL NEAR CARSON CITY, NEVADA.

Written for the MINING AND SCIENTIFIC PRESS
By JOHN A. REID.

The geologic history of the Sierra Nevada must be interpreted largely through a knowledge of the Tertiary rivers whose channels are so well preserved upon the western slope of the range. These ancient channels are economically important for their store of gold, which has added many million dollars to the world's treasure. There is thus a

Buried Gravel Exposed by Faulting.

double interest in the old rivers of the Sierra, that of the scientist and that of the miner, and the latter individual must not forget that his highest interests are best served by pushing scientific inquiries to the farthest point possible, for science is the partner of industrial art.

At the present time our knowledge of these Tertiary rivers is confined to those on the west slope of the range. From the discovery of gold in California, through the first wonderful days of mining, down to the vicissitudes of recent times, the miner and geologist alike have investigated the channels of the old westerly flowing rivers, until our knowledge of them is fairly complete. Nothing, however, has been noted concerning Tertiary rivers east of the summit of the Sierra. There is a large and well defined channel on the east slope that needs description, both for purely scientific and commercial reasons. The details of the geologic bearing of this old river upon the history of the region will be presented as part of a larger paper now in preparation; it seems advisable at this time and in this place to present such facts about the channel as appertain to the mining industry.

This Tertiary river is found between the northeast corner of lake Tahoe and Washoe lake, and lies about six miles northeast of Carson City, Nevada. It crosses the east summit of the Sierra Nevada, there being two crests in the east-west section of the range through lake Tahoe. No traces have been found west of the lake, but scattered gravels on the hills of the Virginia range, east of Washoe valley, indicate its original extension farther in that direction. One of the old stories commonly heard at Virginia City concerns the finding of gold different in character to that of the Comstock in gravels underlying American Flat, west of Gold Hill. The portion of the channel preserved is remarkable in that, unlike the well known ones of the same age to the west, it traverses a region intensely broken and faulted, the great fault-zone of the Sierra Nevada. Precipitous scarps and gently rounded or flat summits characterize the topography. The latter in part represent the old eroded surface of the region at the time when it was drained by the ancient river and its tributaries. The topography is also characterized by a large well formed longitudinal valley, called Little valley. A second similar but much smaller valley lies east of the larger about two miles, and two other smaller ones are found still farther east. Each follows the plane of a north-south fault and separates two adjacent portions of the old river. The larger valleys are flat-bottomed, though less than half a mile wide. With their groves of tamarack pine along the floors, and their steeply rising walls, once well timbered but now only partly covered with low shrubs, they give a park-like aspect to the landscape.

The rocks of this area are few in number. The well known grano-diorite of the Sierra Nevada forms the only bedrock, the gravel resting directly upon it. A small residual spot of older schist, into which the grano-diorite is intrusive, occurs a few hundred feet south of the channel in the eastern part near Washoe valley. There are two rocks of later age than the gravel, both of volcanic origin. These, in order of relative age, are rhyolite and andesite. The rhyolite is white when fresh, weathering to pink. Frequently it is a breccia in its lower portions, and massive,

Buried Gravel Outcrops, Little Valley, Nevada.

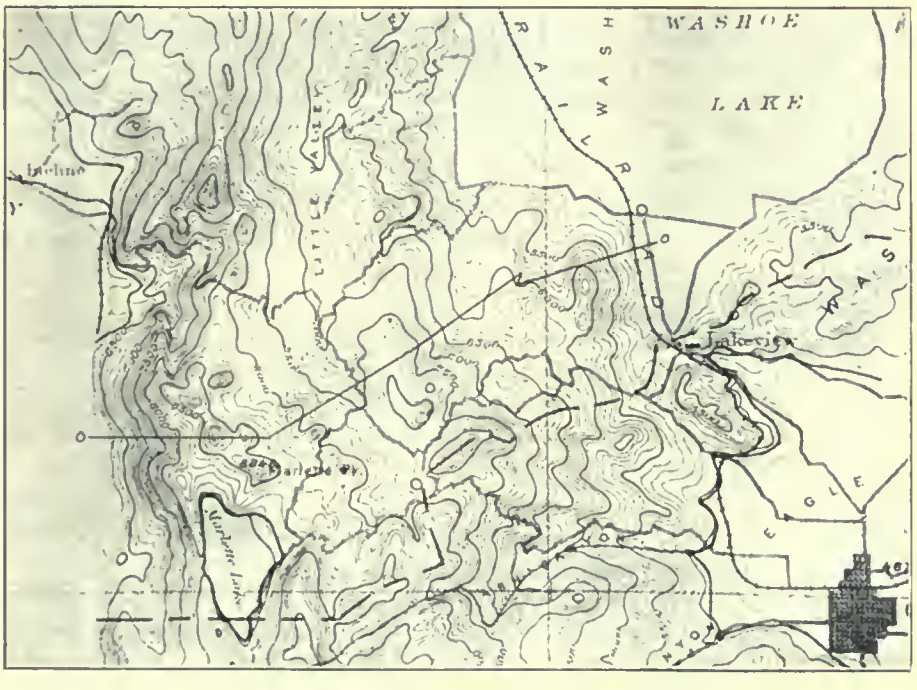
often slightly vesicular, above. It rests directly upon the gravel over a large part of its length, as shown in the section. In the main this cap is not thick. Connected with the acid lava are certain small occurrences of pitchstone, one of which, as a dike, is found just north of the gravel south of Washoe valley. The other volcanic is a hornblende andesite, of steel-gray to black color. This rock occurs in small isolated areas near the old river. In only one of these spots does the andesite actually overlie the gravel, and there but to a small extent. East of lake Tahoe the two volcanics have not been found in jux-

taposition; west of the lake the rhyolite underlies the andesite, as is also the case to the north in the Virginia range near Reno.

The section across the range through the river-channel affords a striking example of geologic structure. There exist seven distinct fault-blocks, each

Tamarack Flats, Little Valley, Nevada.

of which bears a remnant of the river-bed on its crest. The westernmost occurrence of the waterworn material is found at an elevation of 7900 ft. in a small exposure under the edge of the rhyolite area north of Marlett lake, on the upper part of the magnificent fault-scarp that here rises directly from lake Tahoe. No other traces of the river are found on this west fault-block. The length is presumably between half and three-quarters of a mile. Abutting against the



Topographic Map Showing Ancient River Channel.

east edge of the first rhyolite cap is a large outcrop of the gravel on the second section of the channel. Here the highest point is reached by the river deposit, 8700 ft. From this place to the bottom of Little valley, upon the summits of the two fault-blocks, the gravel persists in an irregular manner. The actual width of the channel is masked by rock disintegration and the action of recent forces of erosion and deposition. From surface indications this dimension is large, reaching a quarter of a mile or more at Little valley. At the summit the width is roughly 300 yards. The old river-bed has been tilted to the east in the second and third block; the condition of the first is unknown. In Little valley the gravel lies between the contours of 7200 and 7500 ft., the upper portion only being shown; therefore the

Little Valley, Nevada, Looking South.

bottom of the channel west of the creek in Little valley is probably several hundred feet below the bed of the creek. The length on the second and third blocks is about two miles. The fourth block, with its load, lies between the third and the second largest longitudinal valley.

The finest exposure is found on the east wall of Little valley, where some idea of the size of the ancient river can be gained. The north-south fault through the largest valley has caused the up-throw of the east block, thereby making an incomplete vertical cross-section of the watercourse. The best portion of the exposure shows the gravel resting upon the north side of the bed, which dips to the south. The photograph shows this feature. The gravel rises steeply above the floor of Little valley toward the flat crest of the ridge. The thickness is at least 500 ft., with the bottom not exposed. It may be suggested that part of this thickness is due to faulting, but the rhyolite, which caps the ridge and in part the gravel, fails to confirm this idea. The width here is 300 or 400 yards, giving a large volume of deposit. On this fourth block to the east the lava covers the channel, and a comparatively small outcrop appears near the top of the steep scarp. The elevation of the bottom of the channel on the west side is approximately 7100 ft.; on the east side the elevation is 7500 ft. This indicates a tilting to the west. Further, although full details are yet to be deciphered, the posi-

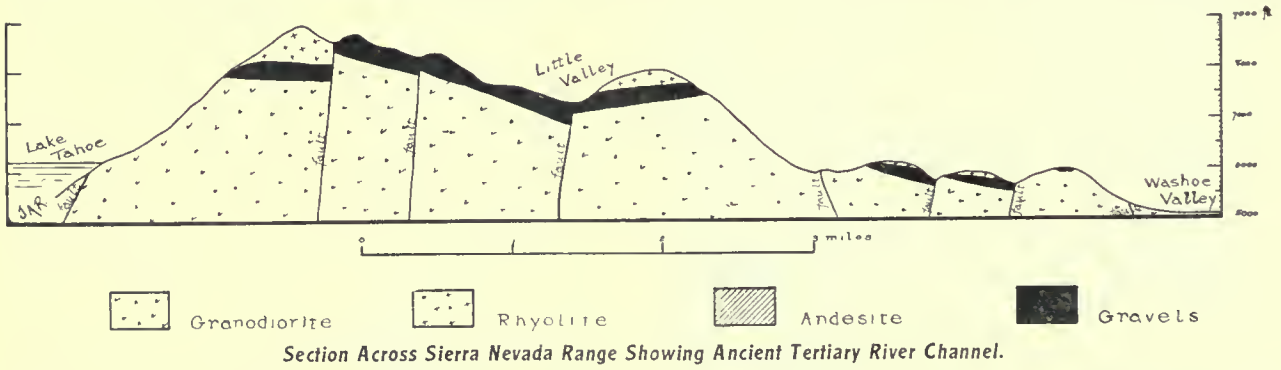
tion of the rhyolite upon the gravel may possibly indicate some tilting before the volcanic flow. The channel on this block has a length of nearly a mile. Across the second longitudinal valley a large part of the old river is missing, the gravel being found scattered in the present streams to the northward. The next two blocks are closely associated, at low elevation, and are largely lava-capped. The fifth fault-block carries only traces of waterworn material on the west side, but a deep deposit on the east, in one of the smaller longitudinal valleys. The elevation on the west is 5900 ft., on the east 5750 ft., with bottom not in evidence. The thickness at the latter place is about 300 ft. The width is uncertain, but is only a few hundred feet at most. This small dimension is almost certainly due to east-west faulting parallel to the channel, as both gravels and rhyolite capping cease suddenly to the south. Here again are details carefully to be worked out, particularly after more mining exploration has opened the ground beneath the surface. The length of this fragment is about half a mile, tilted to the east. The sixth block is also tilted eastward, the elevations of the gravels on the west and east respectively being 6000 ft. and 5700 ft. A horizontal element of the north-south fault that separates the fifth and sixth blocks has caused the latter portion to shift a few hundred yards to the south. A complex of small faults at this point renders further investigation necessary. No dimensions except the length of about three-eighths of a mile are obtainable, for the deposit is to be seen only along the south edge, where it lies beneath the thin rhyolite cap. The latter is in part a breccia. The seventh, or last, portion of the river channel occurs on the large symmetrical hill just west of the south arm of Washoe valley. The fault-block that forms this hill has been elevated relatively to those adjacent, with the result that the gravel upon it is found at a height of 6000 ft. and over. A small amount only is present, and no well preserved section of the river-bottom. On the east of Washoe valley the scattered boulders and pebbles were found at an elevation of 5500 ft. A rather large deposit of the same is found northeast of Carson, at a place where a small wet-weather stream debouches upon the floor of Eagle valley. This occurrence is undoubtedly due to the erosion of the original river-bed and re-deposition at a lower spot.

The gravel consists of well rounded pebbles and boulders of the bedrock complex of the Sierra Nevada, and includes quartzite, meta-andesite, schist, grano-diorite, and some pebbles of a more basic crystalline rock—probably a gabbro. Decomposition prevented the precise determination of the last rock mentioned. In the gravel of the fifth block, at the exposure shown in the photograph, a large number of boulders of iron ore occur. This ore is hematite in lustrous black plates, accompanied by some magnetite. It is associated with quartz and metamorphic rocks. In size the gravels range from 6 and 8 in. boulders down to small pebbles less than one inch. The coarser material appears to occur toward the bottom of the channel.

The exact position of the gold cannot yet be ascertained It seems to be well distributed on the surface and wherever mining has been done. The size of the well-rounded grains varies from that of mustard seeds to that of coarse nuggets.

Prospecting Buried River Gravels.

A question of interest, both to the geologist and miner, is the flow of this Tertiary river. Exposures being so few and poor, and no fresh contact of gravel on bedrock being yet brought to light, direct evidence, on the other hand, all indicates an eastward movement of the current. The gravels are composed of rocks exactly similar to those found to the west, and not to the east within reasonable distance. The quality of the gold is Californian, rather than that of the Great Basin deposits. The summit region of the Sierra, now chiefly granitic in character, was once covered with a great thickness of altered rocks, just as are the lower westward slopes today. In these altered rocks it is probable that gold-bearing quartz veins were present. The metal from these was carried away by the ancient streams and depos-



Section Across Sierra Nevada Range Showing Ancient Tertiary River Channel.

ited in favorable sites in their beds. The gold in this particular river is probably of such an origin. Furthermore, if the river were a westward flowing stream, it seems difficult to account for the entire absence of a large channel west of lake Tahoe in line with the one east of the lake.

The mining done has been of the rudest sort, and at only a few places. In Little valley, in the third portion, a tunnel has been driven southerly into the deposit. The value of the gravel struck is not known. In the early days near the same place shallow cuts disclosed a pocket beneath a portion of the gravel, from which it is reported $60,000 was recovered. The more recent work in Little valley has made evident the presence of much east-west faulting parallel to and through the channel. The same faulting is one of the larger characteristics of the fault-zone. In the immediate area under discussion the general effect has been to raise the country to the south, thus dropping the north edge of the river deposit. In the east side of the river portion there

Scene in Little Valley, Nevada.

has been a little work. A shaft and an incline have been sunk, but a super-abundance of water made the openings of little value. The bottom of the channel was not reached, according to the man who performed the work, and not sufficient gold to pay for this method of mining was found in the upper gravel. The sixth portion, along the south side, is that which has received the most attention. A series of shallow open-cuts have been dug on the northward sloping bedrock, the dirt from which was ground-sluiced. Rockers and long-toms have also been used. The amount of gold obtained from the Tertiary river-bed is uncertain. Mr. Robert Seavers, of the Nevada State University, who has lived near this locality for many years, informed me that about $100,000 in all has been recovered.

Mining has been not only desultory, but also spasmodic. Nothing has been done within the last few years except driving the tunnel in Little valley. The higher portions are known to contain much gold in places, nearly sufficient to pay fair wages to a man with no more than an ordinary miner's pan. The fact that this ground is owned by the Virginia City Water Co. prevents more work being done. The portions south of Washoe valley may be further explored, but excess of water and a cap of lava have discouraged local operators.

To become commercially profitable the gravel must be worked in a large way by hydraulic methods. This places the problem as one of water-supply, to be controlled by the water company. As a matter of possibility, it is evident from the topographic map that water can be brought to all sections of the channel except those at the highest elevations. If the gold content justified it, as is not improbable, other methods for working these elevated portions might be used. Much water that performs no useful work is running off these hills, particularly at the period of melting snow. Exact engineering data are not at hand, though doubtless they might be obtained by proper arrangement with the water company. The present indications and conditions appear to warrant a serious consideration of the exploitation of these gravels in a large way.

Reinforced concrete mine-timbers, if such a hibernianism may be permitted, have been introduced by D. W. Shepard of Denver, involving a new method of reinforcing by trussed rods. By this system greater resistance is given to lateral strains, increasing the strength of the concrete member in the direction in which its weakness has in the past proved an obstacle to its use. Thus, it is claimed, caps of reinforced concrete may be made having within less compass and lower cost than ordinary timber, decidedly superior strength. The reinforcing rods employed are of ½-in. steel, and the size of post and cap proposed as standard by Mr. Shepard is 4 by 9 in. For permanent shafts and gangways it is conceivable that a system of this kind may present advantages which will commend it to increasing favor among mine managers, on account of the rapidly growing expense of timber and the generally decreasing cost of cement throughout the country as a result of competition.

A case of rapid repair to a power plant occurred recently when an engine at the Davidson Rubber Works in Charleston, Mass., was wrecked just at the close of the day's work, the cylinder-head and frame being demolished and the crank-pin broken. Two days later an order was placed with the Allis-Chalmers Co. for a 20 by 48 in. engine, and the new foundation was begun. The engine was shipped by express three days later, and on the fifth day after letting the contract it reached its destination. Parts of the old engine were used again and the crank was re-bored to fit the new pin. The erection was complete and the engine working under full load ten days from the date of placing the order.

The cost of dredging under favorable conditions should be estimated to be 8c. per yard for operating expenses and depreciation. Much lower results have been published, but these are often based on short periods or inaccurate book-keeping. Large dredges of 80,000 cu. yd. per month may average as low as 5c. for operation and depreciation.

MINING COSTS IN THE JOPLIN DISTRICT.

Written for the MINING AND SCIENTIFIC PRESS
By DOSS BRITTAIN.

The recent low prices in the spelter market and the resultant decline in the price of zinc ore have brought seriously to the minds of operators and investors the matter of mining costs in the Joplin district. The failure to make a correct estimate may lead to serious mistakes, not only on the part of the investor, but on that of the operator as well. Costs include the expense of mill and underground equipment, royalties, labor, power, explosives, insurance.

For an average acreage in the sheet-ground territory $35,000 for mill and underground equipment should be ample, $10,000 extra for prospecting, shaft-sinking, and opening up the ground in such manner as to supply the mill with material is a fair allowance. In the case of average sheet-ground, with due judgment exercised, this sum should prepare for mining a good run of ore.

The royalty depends on whether the operator is fee-owner, first or second lessee. If he is fee-owner there is no royalty; if first lessee, the royalty is from 10 to 15%; if second lessee, or sub-lessee, it is 20 to 25%, and sometimes as high as 30%. There are cases in the district where the first lease royalty is as low as 7%, but this is uncommon. The royalty in all cases is calculated on the gross sales of ore, the check in payment being made out to the fee-owner, who takes out his royalty, the remainder being transmitted to the lessee, who, if there is a sub-lessee, takes his royalty, and so on till after all the royalties are paid, the return from the ore sales reaches the operator, who must stand all mining expenses.

The workmen employed in a zinc and lead mine are paid as follows:

Engineer	$2.25	to	$4.25
Fireman			3.00
Hoist-man	2.50	"	2.75
Boulder-breakers			2.00
Tub-hookers	2.75	"	3.00
Shovelers (6 to 7c. per can)	3.00	"	3.50
Machine-men			2.75
Helpers			2.25
Powder-men	3.25	"	3.50
Pump-man	2.75	"	3.00
Tub-runner			2.25
Track-man			2.50
Crusher-feeder	2.25	"	2.75
Jig-man	4.00	"	5.00
Jig-man's helper			2.25
Sludge-men	2.00	"	2.25
Blacksmith	2.50	"	2.75
Boss (day)			5.00
Boss (night)			3.00

The superintendent is usually paid $150 per month.

There are three forms of power in use in the Joplin district, namely, steam, gas, and electricity. The cost of one horsepower-hour with the use of steam, and with coal at average prices, is 1.75 cents, running non-condensing, as does the ordinary steam-plant of the Joplin mill. Steam power with gas, non-condensing, costs about 0.75 c. per hp.-hr., while with gas condensing the cost is reduced to 0.5 cents. With gas in the ordinary type of gas-engine power is guaranteed to the operator by the gas-engine companies at 0.3 c. per hp.-hr., while some makes of engines actually produce it at 0.25 c., gas in the district being furnished at 1 c. per 1000 ft. Power by electricity is produced at 1.25 c. per hp.-hour.

The cost of explosives per ton of material broken varies greatly, but even in hard ground it should not exceed 10 to 12 cents.

Mills are insured in the Joplin district at a rate of $2.50 to $5 per $100 valuation, depending wholly on individual conditions. Companies are protected against all liability suits at a rate of 3½% of the payroll.

The actual cost of placing a ton of zinc concentrate in the bin is variously estimated from 50 cents to $1.50, the latter estimate including all the necessary expenses involved in a year's work, pumping, exploring, timbering, construction work, and general expense. The operation of mining crude ore includes:

Breaking ground	$0.41
Shoveling	0.21
Hoisting	0.14
Pumping	0.10
Exploring	0.10
Timbering	0.01
Total cost of mining	$0.97
Milling	0.25
General expense	0.14
Construction	0.12
Total cost	$1.48

The percentage of recoverable ore and the price therefor determines the amount of profit to be made. These figures are taken from a year's operation of a mine in hard ground.

The cost of handling a ton of material in the sheet-ground is itemized as follows:

Explosives	$0.12		
Shoveling	0.12		
Other labor underground	0.10		
Hoisting	0.01		
Milling	0.15	to	$0.17
Total	$0.50	to	$0.52

In the second estimate it will be observed that such expenses as pumping, timbering, exploring, and construction work are omitted, thus accounting for the great difference in cost. Timbering, of course, in sheet-ground is practically nil. The large difference in the cost of hoisting is accounted for by the fact that the first estimate includes also the hoisting of dead material as well as that milled. The difference in the milling is due to difference in the size of mills, those of the sheet-ground being of large tonnage.

Canvas pipes were always used in California for hydraulic mining in early days. Toward the end of 1853 pipes made of light sheet-iron were introduced to replace them. The first iron pipe was used by R. R. Craig on American hill, Nevada county. It consisted of about 100 ft. of stove-pipe. In 1856 a firm in San Francisco commenced the manufacture of wrought-iron pipes, and during 1857 a sheet-iron pipe 40 in. diam. was laid for a water conduit across a depression at Timbuctoo in Yuba county.

A MAKESHIFT ROASTING FURNACE.

Written for the MINING AND SCIENTIFIC PRESS
By HERBERT W. ROSS.

The Union Copper Mining Co. of Calaveras county, California, has a small smelter at Copperopolis. There is but one furnace, an oil-burning reverberatory. In the past, ore from the company's mine has been roasted in piles placed on the hill immediately back of the smelter. When burned these piles were covered with a temporary roof to exclude rain, and transferred as needed to the bedding bins behind the furnace. It was necessary to shovel the ore twice before charging it into the furnace hoppers. The original plan was to install McDougall roasters and treat concentrates, but the construction work was suspended.

The heap-roasted material charged into the furnace was of course cold and over-roasted. Owing to inadequate crushing facilities, rather coarse ore was delivered to the furnace. In order to prevent slag and matte from splashing on the roof, it was essential to dry damp ore before charging.

The average sulphur content of the ore received from the mine is about 13%. Several piles were built averaging less than 10% sulphur. The pine wood under these piles became saturated with water during the winter, and it was found impossible to fire the heaps. It became imperative to find a means for roasting this ore economically.

The reverberatory furnace is connected with a dust chamber 124 ft. long, and 12 ft. wide, 84 ft. of its length being covered with a sheet-iron floor. The chamber is built on the same level as the furnace. This dust-flue suggested itself as a substitute for a roasting-furnace, the waste heat from the reverberatory being utilized for roasting. This waste heat is excessive, owing to the infusible character of the highly aluminous slag that we are forced to make.

Five small charge hoppers have been placed in the runway above the dust-chamber. Seven sheet-iron discharge-chutes have been fastened to the side of the chamber so that hot calcine can be run by gravity into cars on the furnace-floor below. A hydraulic elevator that connected the furnace-floor and the charge-floor furnished a means for raising the roasted material to the furnace hoppers. To facilitate the handling of calcine, track was laid beneath the discharge-chutes of the dust-chamber and over the charge-hoppers of the reverberatory furnace. The total cost of labor and new material for construction amounted to $192.

As the furnace is connected with the middle of the chamber, it was necessary to supply heat to one end by means of an oil-burner. Ore and flux are delivered to each roaster-hopper in 1000-lb. charges, the rate of charging being so regulated that the desired amount of sulphur is expelled. Conical piles form beneath the charge-hoppers, fresh charges of ore spreading over the surface of the piles to a fairly uniform depth. We are unable to rabble the ore while roasting, and depend on each thin layer roasting sufficiently before the next is added. When enough ore has accumulated in one of the piles to make an eight-ton charge for the furnace, it is removed and the remaining calcine leveled before adding fresh ore. About 5% combined water and one fourth of the sulphur is expelled from the ore by this method of roasting.

We are able to obtain about 50 tons of hot calcine per day that will yield a 45% copper matte on smelting. The advantages of charging hot material have warranted the use of the furnace, regardless of service as a roaster. Both ore and flux are charged into the furnace hoppers at a red heat. Larger charges are permissible when using hot material, the charge spreading well on dropping. As the combined and free water have been expelled from the ore, little splashing occurs; this permits of charging more rapidly than is advisable with cold calcine, if injury to the roof is to be avoided.

Roasting in this furnace would enable us to handle green ore low in sulphur more economically than if heap-roasting is employed. Shoveling can be entirely avoided by the use of hopper-bottom bins. No precautions are necessary to keep the ore dry. A large ore-supply at the smelter will not be required. We have a method for roasting ore too low in sulphur to be suitable for heap-roasting. If the sulphur content is high or the ore finely crushed, the roasting is unsatisfactory. While the roaster cannot be regarded as very efficient, it enables us to roast the rather coarse material from our crushing plant and expel the small amount of sulphur we desire to burn off. Several thousand tons of low-grade ore have been smelted that could not have been treated without the use of the dust-chamber.

Stope drill competition has again been taken up in South Africa, the recent tests evidently not seeming conclusive. The Transvaal Government, in co-operation with the Transvaal Chamber of Mines, has arranged for a practical trial of small rock-drills suitable for narrow stoping work under the working conditions obtaining on the Witwatersrand. All types of rock-drill are eligible to compete. Drills using compressed air will be supplied with a pressure varying from 60 to 75 lb. per sq. in. at the working face. The mining regulations require the provision of dust-allaying appliances, and competitors must make provision accordingly.

Two prizes, of £4000 and £1000 respectively, are offered. The trials and the judging will be so arranged as to decide which machine performs the most economical work. The competition will commence early in 1909, and entries will probably close with the end of 1908. The trials will last about six months, the drills being tested in the first instance on the surface, and those considered suitable being given a more prolonged test underground in several stopes in various mines on the Witwatersrand. The detailed conditions governing the competition, including the exact date of closing entries, will be published as soon as possible.

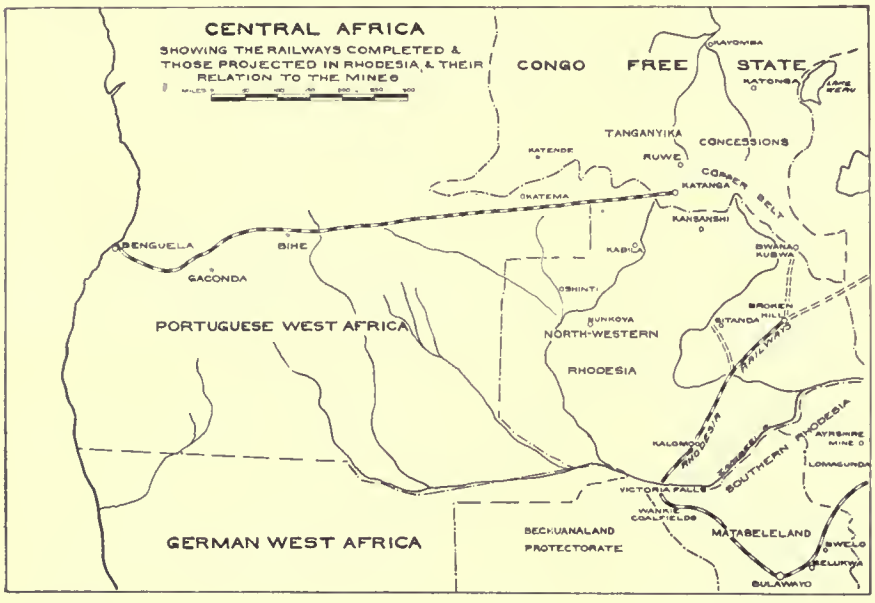
All enquiries should be addressed either to: The Secretary, Stope Drill Competition, Transvaal Chamber of Mines, Johannesburg, Transvaal, or to: The London Secretary, Transvaal Chamber of Mines, 202 Salisbury House, Finsbury Circus, London, E. C.

KANSANSHI MINE AND MINE SAMPLING.

Written for the MINING AND SCIENTIFIC PRESS
By J. R. FARRELL.

Kansanshi is the name given to an ancient copper mine situated at an elevation of 5000 ft. on one of the higher ridges making south from the Congo-Zambesi divide in northwestern Rhodesia. It is within 12 miles of the Congo Free State and is owned (as to 65%) by the Tanganyika Concessions Ltd. and (as to 35%) by the British South African Company.

Near the centre of the area is a low rounded hill on which are many trenches, and from this extends a series of parallel cuttings, mainly toward the south, from which former workers extracted a large tonnage. There are six principal lines of these cuttings, which vary from 300 to 1300 ft. long, from 3 to 30 ft. wide, and as much as 25 or 30 ft. deep. Along the sides are piled almost continuous heaps of stuff,



which in the aggregate make many thousands of tons but are not nearly sufficient to account for the material that has been taken out. These imposing cuttings, with their walls standing intact, make a splendid exposure of the upper portion of the vein, showing a dip to the east and the fracturing of the sandstone layers at nearly right angles so as to suggest a persistence in depth at least through the sandstone. Under conditions heretofore existing in that remote land it was not practicable to approximate the thickness of this surface sandstone, and any statement would have been a mere guess.

To test the mine below the old workings, shafts were sunk to 80 and 100 ft. and drifts extended on three of the veins: the broken rock was wheeled in barrows or carried in boxes to the shafts, dumped, shoveled into bark baskets, and windlassed to the surface by natives. In this manner a drift was made on D reef in continuous ore, averaging 8 to 10 ft. wide, for over 1000 ft.; on E reef, for more than 500 ft. on ore 2 to 3 ft. wide; on the 'new reef' for nearly the same length and 4 ft. wide. All these workings are on the 80-ft. level. In these drifts the ore was massive, filling the fissure from wall to wall, and in addition there was an impregnation of the sandstone from 6 to 10 ft. on either side. The ore exposed was of highest copper content toward the north, under the hill, where also was found a good excess of iron, but going south the copper grew gradually less and the iron was in like manner replaced by silica, but as opened, by care in mining, a self-fluxing mixture was obtainable for a length of 1000 ft. The copper ores were almost entirely carbonates and oxides, and the iron occurred as limonite, but sulphides of both metals also appeared. Detailed sampling showed all this ore to average 18.7% copper and $2 or $3 in gold. This was highly satisfactory, but not sufficient to justify a 300-mile extension of the Rhodesian Railways from the terminus at Broken Hill to Kansanshi, and therefore it was agreed to test the mine to a depth of 300 ft. This was an arduous and expensive undertaking, for a road had to be cut 300 miles through a wooded country, crossing rivers and swamps, and machinery for hoisting, pumping, and testing had to be brought by ox-teams, with the certainty that the oxen would die from bites of the tsetse fly and the wagons go to the scrap-heap. A new shaft was sunk and a level made at 134 ft., corresponding to 100 ft. of the previous work, and the different veins were again cut and explored, with excellent results. At 149 ft. the shaft passed out of the sandstone into a hard, slightly pyritic, and nearly barren limestone, in which it continued for 120 ft. Winzes were put down on the different veins and these bumped into the limestone, the veins one after another turning into the sandstone, bending to the west, and pinching out.

After the limestone had been entered the mine was examined by four engineers and one geologist, all holding important positions, and all of them assumed that the sandstone was lying conformably upon the limestone into which, so they stated, the copper veins did not penetrate; in other words, the mine had been bottomed. Yet at the time four of these investigators were at the property, the following exposures had been made, namely, at a depth of 234 ft. cross-cuts had been started east and west in the limestone; at 35 ft. east of the shaft the ore had passed into black schist dipping 7° west; the bottom of the shaft had entered similar material; the main cross-cut on the upper level had been extended west beyond the ore veins and was in black schist; and in the other direction, under Kansanshi hill, the sandstone had been gradually altered into quartzite.

However, the importance of these facts as noted in the former statements of weekly progress reported to London was appreciated, and a cable was sent to the local manager to sink a winze from the extreme west end of the upper cross-cut. The result was that, even before some of the engineer's opinions were at

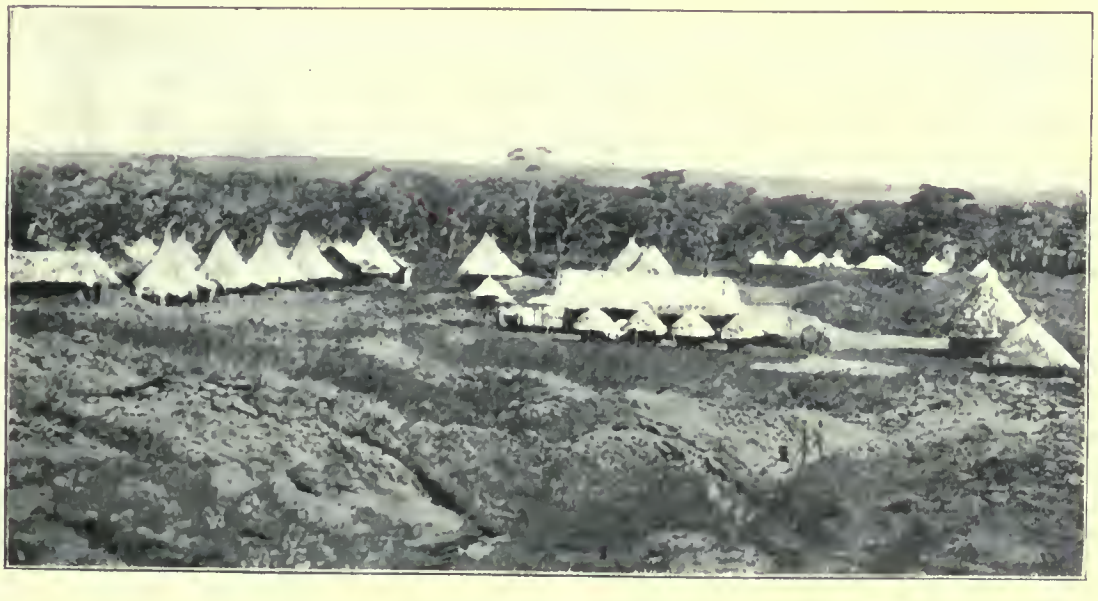
hand, the manager reported this winze had cut a strong vein of good ore dipping 70° west with a limestone foot-wall and a schist hanging wall. Sinking on this vein continued, the cross-cut west on the second level was also extended and connection made in a wide vein of fine ore, a body of water being also tapped. The latest reports state that the vein is holding so well that indications point to its being very persistent and that the copper-bearing solutions came from below. The carbonate ores continue and it is not known as yet where the sulphide zone will appear, but all the sulphide so far found has been rich.

It looks now as if the following had taken place at Kansanshi: In a former geological period a disturbance tilted the country so greatly as to uplift the limestone bed to its present position with a dip of 70° west and caused the formation of the copper-bearing vein. Next a bed of sandstone over 150 ft. thick was deposited unconformably upon the tilted limestone. Gradually vapors accumulated, because of thermal activity, exerting a pressure that altered some of the sandstone into quartzite and finally forced up Kansanshi hill, fracturing the overlying sandstone along the great series of surface veins, which became filled with their present copper content. Some of the solutions also overflowed, so as to kill the vegetation of the 70 acres of country about the site of the present mine, though woods cover the country outside of this particular tract.

This development has been important and valuable for the Kansanshi mine, but is of much more interest as a straw indicating what may have happened at the Katanga copper mines immediately to the north. It is now understood and admitted that Katanga is a copper zone extending for 200 miles in a sandstone country containing large and valuable deposits of oxidized copper ores. In each of these deposits, the widths of several being measured in hundreds of feet, is a central core of porous quartz ore on either side of which is a wide layer of most beautifully stratified and laminated sandstone ore, and the grade is such that there will be little or no difficulty for many years in maintaining an average of 15% for a plant handling 1,000,000 tons per annum. In places these deposits dip with the sandstone layers, at others they

Kansanshi, Shaft E.

are nearly at right angles; they are found in anticlines, synclines, and rolls, but ordinary theories for copper deposits do not account for their occurrence. Each of the engineers who has visited the region has advanced his own theory as to their origin, and it is peculiar and noticeable that one and all have pursued the unusual method of referring more or less directly to the formation of the continent of Africa itself, speaking of when it was oceanically immersed and uplifted. This may indicate the extent and importance of the region, but when engineers start with the



Kansanshi Camp, 1902.

creation of a continent, it hardly can be expected they will be in close agreement as to the exact genesis of local mineral deposits. The region is so remote, the difficulties in the way of investigation so onerous, and the need so slight for making deep workings on hills that will yield millions of tons by quarrying; that it must be a long time before close study definitely determines the nature and origin of the ore-bodies. In the meanwhile such facts as are contributed by the development at Kansanshi are of more than passing interest.

One other fact has come to light to which it would be inexcusable to refer but for this tendency to theorize on a continental scale. Far off to the west, where, 1000 miles along the watershed from Katanga, the Central African plateau breaks away to the Atlantic littoral, another ancient copper mine was found, at Kasenya hill. The slope below the old workings was covered with float, and some tons of this were gathered and sent to London for investigation. It was found to have no commercial value, for it carried only 3 to 4% copper and the rest silica, but it was interesting material. Boulders, like cobble-stones, were found thinly crusted with chrysocolla; chunks of sand showed the grains loosely cemented by the same material, while pebbles, rock fragments, and loam were similarly held together, while now and again specks and small splashes of flour-gold were visible. It was the very stuff that would result from water carrying chrysocolla and gold in solution trickling down the side of a hill. Three cross-cut entries were made under the old workings and these cut a mass of brecciated quartz, the pieces of which were crusted and held together, as was the float, and specks of gold were again in evidence. The conclusion was reached that this deposit came from subterranean copper and gold-bearing waters, perhaps a thermal spring, coursing through the broken rocks and overflowing at the surface. This may be another indicator for Katanga.

Referring to all these mines, it will not be out of place for me to recite the following personal experience on the subject of mine sampling: In 1902, as head engineer for the Tanganyika Concessions, Ltd., I was called upon to be the first to visit Katanga, size it up, and lay out such work, if any, as I thought advisable. To reach there, I had to travel over 1000 miles, half of this distance on foot with carriers, north from Bulawayo into Central Africa. Arriving on the ground, I was alone for practical purposes of mining engineering, being instructed to take no man needing European food, other than master of transport, north of the Kafue river, and carrier service from the east coast being delayed, owing largely to a violent epidemic of smallpox in northeastern Rhodesia, I had neither pick, hammer, drill, stick of powder, nor foot of fuse—a prospector's pick and shovel was all I could use. Moreover, food, particularly native food, was scarce. In this shape I was guided along the belt, word being sent to villages in advance so that native food could be provided for one day at a mine and for another to take us to the next copper deposit. So it was possible to remain but a single day at most of the properties, some of which are so extensive that it is beyond the physical endurance of any white man to even walk over them fully in that time and in that climate. The method of procedure was as follows: At daylight I would go to a mine from the night camp to look it over generally; back to breakfast, and then, if the deposit seemed to justify, return with transit and tape-line to approximate the position, shape, and dimensions of the property; back to camp for rest during the hours of mid-day heat, and then out again in the afternoon for such sampling as conditions would permit. On some of the hills no white man had ever before set foot. Even had local conditions permitted close sampling, there was no assay material in Central Africa other than the very limited amount at Kansanshi, over 100 miles distant, and carriers to carry weighty samples in any quantity were difficult to obtain. Even those I had were clamoring every few days to be paid off and sent to their village. Time too was precious, for the rainy fever season was approaching, and it was over 1000 miles through a starvation land back to Bulawayo. These were the conditions under which the Katanga mines were first examined and sampled. It may not have been scientific, but it was all that could be done; yet so well had nature exposed the mines, so enormous had been the native work during the centuries, and so generally similar the ore occurrence, that I was entirely certain of my conclusions and did not hesitate to so report. My business there was to size up a great mineral belt and lay out work to be done upon it, and it speaks well for the country that what was then said and done has not had to be changed in any material particular, and the enterprise has grown meantime into an undertaking of gigantic character.

Now it came to pass about the time my report was made public, technical papers were giving considerable attention to the subject of mine sampling and the apparently 'fairy tales' from Central Africa seemed to afford a good example of how this important work should not be done. It all serves to illustrate how easy it may be to write down comfortably just how some things should be done, and how necessary for the man on the ground to do the best he can.

On the other side is the following: The upper works of Kansanshi were twice sampled in great detail at measured distances and the 'ore fully developed,' 'ore partly developed,' and 'probable ore' calculated to a nicety in different interests, once a few months before and once a few months after the limestone was met with. So finely and accurately was this work done that the average assay-values were identical, 18.7% copper, with a difference of a couple of hundred tons out of many thousand, and yet it was all unnecessary and wasteful. The mine was being opened, hoping to justify the extension of the Rhodesian railway, and if, as was reported, it had been bottomed "and all it would ever yield could be reckoned up," there was no occasion to reckon it up, for it was then clearly insufficient in quantity to justify the construction without which it was valueless, no matter what its grade. It will have to be done all over again some day.

FUMES FROM METALLURGICAL WORKS.

*The devastation of the forests in Tennessee, California, and Pennsylvania, as shown by Haywood and Buckhout, appear to be uncontrovertible evidence of the ravages of smelter fumes. Manufacturers at times have undoubtedly shown an utter disregard for neighbors, and the gases have been allowed to escape, which created havoc. These should be dealt with speedily. The tracing of an injury to fumes, except, of course, in such flagrant cases referred to, is not easy. The proximity of a chemical works with some people is prima facie evidence of the cause of all the trouble. Freytag has stated that the "assumption of an invisible injury done to vegetation by the smelter works vapors and the awarding of damages founded thereon are unwarranted." When smells characteristic of the factory are noted to the windward, the evidence to the lay mind is most convincing. Chemical factories do generate gases that are objectionable. None is surer of this than the manufacturer himself. Sometimes these gases are actually poisonous. Oftentimes they are not. But inasmuch as they smell, they are objectionable. This constitutes a nuisance, and suits for alleged injury from chemical fumes have been a source of great annoyance to manufacturers in consequence. Even when poisonous gases escape by accident, or otherwise, they may be rendered comparatively harmless, if sufficiently diluted. We say 'comparatively,' for, as is well known, the sulphur gases from the combustion of coal in cities on a large scale, aided by soot, do produce slow, but far-reaching and constant injury to exposed works of art, libraries, draperies, and decorations of our homes, as well as those in public repositories. Dr. Baskerville showed that sulphuric acid, calculated at 80 per cent, is produced to the extent of 1300 tons daily in the atmosphere of New York City from the combustion of 9,000,000 tons of anthracite and 4,000,000 tons of bituminous coal per year. This is in addition to the soft coal supplied to steamships. And it has nothing to do with chemical works or smelters. It is simply the result of the amount of coal consumed regularly for heating and other purposes in New York City. From many determinations of the acidity of the air around factories, which as a rule are situated in sparsely settled places, under all kinds of topographical and weather conditions, it has been learned that the acidity is often far less than that observed in large cities. Therefore, placing the blame upon chemical works has not always been a square deal.

The growth of vegetation is affected by many factors, some happening in the ordinary course of events and others occurring only on extraordinary occasions. A weak and stunted growth, smaller leaves, shorter twigs, lack of normal green color indicates unfavorable conditions for growth. The inattentive multitude attribute such a state of affairs to drought, heat, frost, blight, smoke, or gases in the air. These 'gases in the air' may come from legitimate sources, but it must be remarked that however perfect the smoke consumption may be, the sulphides are still in a large measure burned to the oxides of sulphur. This may be obviated only by the use of electrical energy or peat or wood or of producer gas for power and heating purposes. The former are out of the question now on the score of expense. Thirteen billion cubic feet of gas were sent out on the island of Manhattan in 1906. This gave only 230 tons of sulphuric acid into the air, a minor item when we contemplate the other figures. Dr. Schaefer has pointed out that the presence of sulphur dioxide in the air may be the cause of respiratory diseases, yet it is fortunate that it also exercises a disinfectant action as well. A more serious cause of disease in large cities is street dust. This will not be done away with until the automobile has replaced the horse. Until that occurs the objectionable sulphur dioxide does serve a good purpose.

Chemical works, as a rule, are not operated by small concerns. Any large corporation, especially if it has acquired the pseudonym of a 'trust,' unfortunately is looked upon as fair game for a species of blackmail. Especially is this so where there is a semblance of truth beneath the claims. In rural communities, where factories are usually located, the farmer with half a case, if he be not first worn out or financially embarrassed by the familiar repeated delays in securing a trial, will obtain a verdict against such an organization as long as the present sociological and political ideas obtain in those communities, or until certain abuses of the centralization of capital are remedied. And the 'good trust' suffers with the 'bad trust' as a result. To obviate injustice, Professor Baskerville has suggested, perhaps not for the first time, that such suits, dependent upon technical knowledge, be settled by a commission of experts, properly appointed, which shall first determine if damage has been done, and then the amount which should be paid in compensation. In this connection it may be said that there is neither uniformity nor definiteness of statement in the codes of our several States in regard to the contamination of the air or the pollution of our streams. When a plant in New Jersey may generate gases which are complained of in New York, or when smelter fumes produced in Tennessee affect the vegetation in Georgia, it becomes a Federal matter. We are not over-enthusiastic on the rapid growth of the paternalistic policy of our Federal Government, but it would appear to be advisable for the Department of Agriculture to extend its investigations, co-operate with similar departments of the several States, and recommend the enactment of a uniform and definite law. The Government officials would undoubtedly receive cordial co-operation on the part of the works owners.

*From 'Electrochemical and Metallurgical Industry,' April, 1908.

The sides of the Culebra cut on the Panama Canal are to be cut smooth by channeling machines. The canal commission has purchased 24 Sullivan channelers of the largest size, and will put them in use at Culebra, when the lower part of the excavation is undertaken. The only previous use of channeling machines on a scale approaching this was on the Chicago drainage canal, where channelers were also used in the rock sections.

The Prospector.

Owing to the large number of specimens forwarded to this department, it has been found necessary in future to make a charge of 25 cents to subscribers for each determination, and $3 to non-subscribers.

Aragonite was sent by W. H. W., of Ballarat, California.

A specimen of magnetite came from Alamos, Mex., marked J. R. H.

The specimens received from J. S. L., of Ibapah, Utah, are both quartzite.

C. W., of Wadsworth, Nev., sends: No. 1, white barite; No. 2, black obsidian.

Quartz containing manganese dioxide was received from La Grande, Ore., marked I. H. S.

The two specimens sent by F. B., of Jerome, Ariz., are: No. 1, chalcedony; No. 2, quartzite.

E. W. S., of White Bird, Idaho, sends muscovite and chlorite flakes from a disintegrated chloritic rock.

A specimen of metamorphosed rock, mostly quartzite with pyrite, was received from G. F. Y., of Pony, Montana.

D. F., of Goldfield, Nev., sends rhyolite or trachyte showing a glassy sanidine feldspar and black biotite crystals in a vitrophyric base.

The specimens received from W. E. S., of Quartzsite, Ariz., are: No. 1, quartz with specular hematite; No. 2, altered pegmatitic rock; No. 3, diorite; No. 4, quartz and specular hematite; No. 5, free gold in a metamorphic serpentinized rock. Also a specimen of cyanite-schist was sent.

The poured concrete house heralded as an invention of Thomas A. Edison is novel only in the matter of the forms in which the house is moulded. The moulds consist of cast-iron plates less than an inch thick, with milled edges and faces having flanged joints drilled for dowel-pin and bolt connections. The inner surfaces of the plates will be nickel plated or faced with brass where ornamental finish upon the concrete is required. All the details of bearings for reinforcing rods, and ways for plumbing connections and electric wiring, are provided, and the moulds properly numbered for speedy erection. It is proposed to employ steam or electric platform derricks for handling the moulds in erecting and in taking down. Economy in construction with the Edison system will result only through duplication of the same structure, with the same set of moulds. It is estimated that a set for a two-story house of eight rooms will cost less than $40,000, and that such houses may be built for less than $2000 with cement at $1.50 per bbl. Mr. Edison proposes to use a mixture of 1 part cement, 3 parts fine sand, and 5 parts crushed stone or gravel passing a ½-in. ring.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

The mere placing of a tent and a few tools and a small supply of provisions upon a placer mining claim, are not sufficient alone and of themselves to constitute actual possession. But where a prospector has in good faith temporarily gone away from his claim for the purpose of purchasing provisions or supplies or for any other temporary purpose, intending to return and resume his actual occupation, possession, and labors, such temporary absence is not to be construed to be an abandonment of his right to the ground, and that one of his rights to the claim, and another entering upon the claim during such temporary absence could not initiate any right thereto.

Charlton *v.* Kelly, (Alaska) 156 Federal 433, Oct., '07.

To constitute a mining partnership it is necessary that the joint owners of the mine actually engage in working the mine or in the business of operating the mine. The mere co-tenancy of two or more persons in a mining scheme is not of itself sufficient to constitute them mining partners. But it is not essential that all the tenants join in the work of mining in order to establish the partnership; that relation may be established among such of the joint owners as actually engaged in the working or mining operations. The joint owners not so joining in the work are left to their rights and chargeable by their duties as co-tenants only.

Madar *v.* Norman, (Idaho) 92 Pac. 572, Nov., '07.

A broker was given authority to sell a mining lease on specified terms. He procured a promoter, who combined with the purchaser and fraudulently dealt with the seller for the purpose of defeating the broker's claim for commission. In an action by the broker for his commission the court held he was entitled to his commission though the seller did not know that such promoter and the purchaser were acting in conjunction and though the purchaser obtained was not himself able to buy and pay for the property.

Glade *v.* Eastern Illinois Mining Co., (Mo. App.) 107 Southwest. 1002, Feb., '08.

A statute required coal mine operators to have the roadways in their mines sprinkled, and required the inspectors to see that all possible precautions were taken against the occurrence of explosions which might be caused or aggravated by the presence of dust. In an action by a miner for injuries it was held that the willful failure of the manager or examiner to observe the statute was the willful failure of the operator, though the operator had in fact no actual knowledge of the delinquency of the manager or examiner, and though the examiner had a statutory certificate. And the manager's knowledge that for many days the roadway in the mine needed cleaning or sprinkling, and failed to have it done, was a conscious omission to perform a duty and a willful violation of the statute.

Davis *v.* Illinois Collieries Co., (Ill.) 83 Northeast. 836, Feb., '08.

The fact that a particular brand of fuse furnished by a mining company for use by its miners, was in general use for such purposes, and was favorably known, was not conclusive evidence that the company was not guilty of negligence in furnishing that particular kind of fuse to its miners, and the fact that a better and safer kind of fuse had been introduced within recent years and come into common use, was not conclusive evidence that the company was negligent in using the older kind. Such facts were said to be evidence for the consideration of the jury in determining whether the employer failed to exercise the degree of care required by the circumstances, the nature of the instrumentalities, and the danger to be anticipated from defective appliances.

Wiita *v.* Interstate Iron Co., (Minn.) 115 Northwest. 169, Feb., '08.

GEOLOGY.

By James F. Kemp.

(*Continued from page 500.*)

But there are some further interesting features which are displayed by the volcanic centres. We often find cases where practically the same vent has been active for a long period of time, yet where it has furnished successive varieties of lava in a more or less regular series. Rocks of intermediate composition are usually the first to appear. They yield on analysis 50 to 60% in silica and their specific gravity is of mean values. They are followed by others successively higher in silica and of lighter specific gravity. Then appears a marked drop to the last outbreaks of rocks, low in silica, high in iron and related bases and of relatively great specific gravity. Thus we have what Ferdinand von Richthofen called many years ago "the natural succession of the volcanic rocks." Increasing experience has shown that we must admit some variation in the regularity of this series, and that there is sometimes a recurrence to the first variety, but on the whole, the general succession holds good and involves an important truth. In order to account for it, we have come to believe in temporary reservoirs at depths not so great as to preclude fusion and in which the molten rock stands liquid for long periods of time. An original homogeneous mass then breaks up or differentiates into fractional parts. The lightest or most silicious rises to the top, the heaviest or most basic sinks to the bottom. Successive eruptions are marked first by a rock of medium specific gravity and chemical composition, next by those lighter and lighter, or higher and higher, in silica as the upper layers are tapped off, finally closing with the heavy, basic dregs or settlings of the molten mass. The extinct volcanic areas of Nevada and Arizona have given fruitful evidence upon this point, and where the original type of rock re-appears after its normal period has passed, we have concluded that renewed viscous flow has fed again the reservoir from deeper seated stores.

The phenomena of volcanoes, the increasing temperature as we descend in mines or as we test deep bore-holes with self-registering thermometers, as has been done most of all in America by our Professor Halloek, together with other less familiar phenomena which I do not cite, have all led us to the belief that the temperature of the earth continues to increase as depth grows greater. This conclusion is fundamental to some of the points just made, and is probably well justified. But as regards the profound depths the rate may not hold. Some mathematical students of the subject have reached the conclusion that the rate falls off greatly, and, regarding this, opinions may be said to differ, but there is no good reason to doubt that at least for relatively great distances the interior is highly heated.

Volcanic phenomena and the problem of the interior heat have been the objects of greatly increased interest in recent years because of the remarkable and destructive outbreaks in the lesser Antilles and from Vesuvius. In two particulars, Mont Pélè in Martinique has added phenomena previously unfamiliar. The descending blast of heated gas that wrecked St. Pierre with its tens of thousands of people was on a scale not formerly observed, and by its destruction of life aroused human sympathy as well as stimulated scientific research. The subsequent protrusion of the extraordinary spine of solid yet highly heated lava from the crater gave a striking illustration of a mass of rock passing upward in a viscous state, then solidifying before it emerged, but remaining red hot and steaming after it projected above the surface. Unfortunately it has fallen away and no longer stands as a monument to the dead buried at the foot of the cone.

There is one very recent suggestion regarding the problem of internal heat, with its corollaries, the volcanoes and the earthquake. It is the possible bearing of radio-activity. The recent discoveries that certain rare elements or so-called elements pass through a series of changes, ordinarily described as "breaking down" into other substances, with the parallel development of heat; and the further discovery of the radio-active character of the volcanic rocks and their emissions, have brought prominently before our minds the possibility that herein lies a cause of the internal heat and of the emitted lavas. The idea is so new that it is as yet little more than a suggestion, but we all realize that it may be fraught with important consequences for the future and its development in the years lying immediately before us will be watched with intense interest.

It has been impossible to pass in review the topics hitherto treated without constantly introducing the idea of time, and of time so indefinite in character that we describe it as geological in distinction from the usual measurable durations. Geology brings us irresistibly face to face with stretches inconceivably long which elude our grasp as do the distances of the astronomers. Some bold mathematical spirits have sought to calculate the age of the earth from the assumed nebulous conditions to the present. The results have varied from twenty millions to several hundreds of millions of years. Perhaps one hundred millions is generally accepted as a fair attempt at a solution upon such uncertain data. If we drift away from the nebular hypothesis we lose even these data and must attack the problem along new lines. If A. C. Lane succeeds in establishing from his samples of deep-well water the composition of the pre-Cambrian sea, and if we can calculate the rate at which rivers have poured their dissolved salts into the ocean, then we may attain an approximate idea of the time period required to raise the ocean to its present concentration.

With all these very long durations, great uncertainty is involved. Better success has been met with smaller ones, and in several cases the solutions attain much interest. The Falls of Niagara have furnished on the whole the most significant instance, and the one upon which the greatest efforts have been expended. We can but wonder if when Father Hennepin looked upon them in 1768 and felt overwhelmed, as he tells us, with the tumult of the waters, the thought did not pass through his mind

as to the length of time during which the river had been at work since the crest was seven miles away toward the north. The question looks so simple at first glance that it seems as if it were merely a matter of arithmetic to observe for a time the rate per year of the recession and then divide this into the length of the gorge. If the recession is two feet per year, and the gorge is seven miles long, something like 18,000 years would be required. But we have learned that there are a number of uncertain factors. While the American Falls may retreat less than a foot per year, and even for ten years at a stretch draw back less than two inches annually, the Canadian Falls, after ranging about two feet for many years, may average five for five years running. The crest is now very broad; yet obviously it has been much narrower throughout the greater part of its history. At the Whirlpool Rapids we find an older channel, one antedating the Glacial epoch, which must have headed once somewhere upstream and which can be followed out to the north. Thus, the Niagara river, as we know it on the retiring of the great ice sheet, found a part of its gorge already cut. The part was probably a modest fraction, but we have no means of determining exactly how much. It has also been demonstrated that below the Whirlpool Rapids, at what is called the Foster Flats, the river ran in a narrow western and broad eastern channel, with a small island between, much as now, but on a different scale. Still making all allowances for these facts and variations, and recognizing that the present Niagara began its work when the continental glacier in retreating uncovered its drainage area and outlet, we generally believe that not less than 10,000 nor more than 50,000 years have elapsed.

Within the last few years geologists have been impressed with the line of attack furnished by measurements of radio-activity. It has been shown that not only eruptive rocks, but also both the waters and the surface deposits of up-rising, deep-seated springs display these phenomena in determinable degrees. In the latter case the radio-activity of freshly deposited material is the greatest, and from this condition the amount falls off at a fairly well understood rate per year. If an observer, for instance in the Yellowstone Park, determines the radio-activity of freshly deposited calcareous matter at the Mammoth Hot Springs, and then makes a similar determination on ancient incrustations at the base of an abandoned terrace, the lapse of time since the latter began is within his grasp. In this way we have learned that a thousand years ago a certain deposit began on the glacial drift, and with more determinations of a similar character we may learn when these hot springs first began. The method is very new, but promises results both of importance and of general interest.

Geology touches human affairs most closely on the side of mining and related enterprises, and there is no more interesting chapter in its history than the one relating to these services. Mining is a very old occupation. Civilization could scarcely advance without the aid of the metals, and modern civilization owes one of its greatest debts to coal.

When, however, an engineer is face to face with the actual problems of removing these materials from the earth in the most economical way, and when he must plan such operations for a period of years, it is fundamentally necessary that he should have correct geological conceptions of their origin and structure. That our usual coal seams are ancient accumulations of vegetable tissue, deposited under quiet waters in the long course of swamp growth, no properly informed person can longer doubt. That they have been folded, often faulted, and always eroded until we have but the remnants of their past extent, admits of no question. The simple facts and principles of structural geology lie at the foundation of this branch of the mining industry and have been long established. Nevertheless, as to the exact processes which have brought carboniferous or cretaceous muck, peat, and lignite along the road to the distant goal of anthracite, we are yet in debate. That the original plant tissue of the anthracite seams was so long exposed before burial under the sediments which followed hard upon it, that it had lost the greater part of its volatile constituents and readily became the dense, hard, smokeless coal which we in the East so much prize, is the acute suggestion of Professor Stevenson, and his explanation fits the Pennsylvania case much better than any other. Yet not a few are pondering the question, and some think that a more open-textured cover of rocks has permitted the gases incident and necessary to the change to more freely form and escape in the anthracite areas than in the bituminous. Some again think that the mechanical heat produced in folding, or the interior heat of the earth made available by relatively deep burial under later strata, or the neighborhood of lower lying but as yet undiscovered eruptive rocks with their stores of heat, have brought about the changes. Upon this problem many are therefore still disposed to ponder.

Again, speaking of coals both bituminous and anthracite, we may question as follows: Were they once leaves, twigs, branches, and woody tissues generally, or were they largely spores of cryptogams. If we also admit to our field of view the interesting group which embraces the cannels and the exceptionally gaseous coals, from which to this day illuminating oils are distilled in Scotland and in New South Wales, we may ask: Were they enriched with animal matter such as fish, making them fry and sputter in our grates like so much fat; or were they due to the enormously rapid multiplication of freshwater algae in a single season, as Bertrand of Lille has inferred from his microscopic studies of the Franco-Belgian occurrences. If this is true, then for these coals our old ideas of slow accumulation and protracted time are unnecessary, and carbonaceous deposits may have gathered with a rapidity of which we had no proper grasp. And then there are the strange asphaltic coals which fill the fissures across our strata of sandstone and shale; representing thus the inflow of long extinct petroleum springs, now evaporated and oxidized to a shining black residuum —vein fillings they are, analogous to those metalliferous deposits to which I shall shortly pass. They

connect the coals with petroleum and natural gases and lead us to ask: Whence came the oils that gave rise to them and to our subterranean pools, which have so long remained stored up in the liquid form awaiting the drill? Are they too fractional products from long-buried plants and animals, gradually emitted during decomposition or gentle distillation, as almost all of us in America believe; or are they outgivings from molten rock which has never reached the surface and which has been forced to steam and fume in the confinement of the lower world? A few observers urge this view, and a still smaller number, mostly laboratory workers, without the steadying influence of field experience, have suggested that there are inner zones of the earth composed of metallic carbides, or even of metallic alkalies, to which waters charged with carbonic acid and atmospheric air penetrate and are there changed into petroleum and natural gas. These latter are views flatly contradicted and rendered impossible by the assured physical condition of the interior.

From asphaltic coals in fissures and veins, we pass to the metalliferous minerals in similar relationships. Always when we speak of veins, the precious metals more especially fill our field of view, and what romantic and fascinating chapters in human history they suggest! We mining people think that from the time when primitive man realized his need of metals, no influence in the world's history has been so potent to cause migrations as the desire to find the silver and the gold of new countries. The Spaniards certainly came to North, Central, and South America chiefly to gain them. The Englishmen hastened in droves to Australia. Occidental and Oriental alike formed the mad rush to California. The stolid Dutchman of South Africa was swamped by the flood of English, German, French, and American gold-seekers on the Rand. Nor in our own day could the icy barrier of Alaskan cold stave off the tide of fortune-seekers. We sometimes think that in the settlement of this staid and sober part of America the longing for religious or political freedom almost solely brought the settlers. But the legends of the old silver mines still linger in the Highlands of the Hudson, and the hills of New England do not lack shafts and pits now long gone to ruin. Who will say to what extent these monuments to dead and buried hopes may not indicate the alluring influences of gold and silver in the unknown wilderness.

Wherever rich enough to mine, the metals are found in a greatly concentrated state as compared with the earth at large. They so often fill crevices which traverse the rocks as veins cross the human hand, that the name vein has long been applied in this connection. The figurative use of the word is also happy, in that the metallic minerals, as well as their associates of no value, have been obviously brought to their resting places by circulating waters, which in the miner's phrase have nourished and enriched the crevices as does the blood the body. The veins again are, as it were, wounds or gashes in the earth which have been healed by the circulations. That water has accomplished the task few doubt. The earlier observers were accustomed to attribute the subterranean waters to the rainfall, and until recently all of us who have specially studied these phenomena have fallen in with the same view. From the clouds the rains descend upon the earth's surface. In part they run off in the stream; in part they evaporate, and in part they pass into the ground, where for ages they have accumulated as the ground-water and where they constantly renew the supply. The ground-water fills our wells, pours into the shafts of our mines as we sink, and forces us to pump. It stands beneath almost all parts of the surface, at depths, depending partly on the amount of rainfall and partly on the nature of the rock. We formerly believed that the ground-water continued downward in the crevices of the rocks to great depths, far enough, in fact, to come under the influence of the internal heat of the earth, and that it was set in circulation partly by this and partly by the heat afforded by those portions which, entering the ground on the heights, forced up the shorter columns after a greater or less underground journey. In the depths where heat and pressure were influential the waters were believed to be active solvents, and in their wanderings through the narrow pores and spaces of the rocks they gathered up the metallic and non-metallic minerals and deposited them in the veins when they rose to higher levels. In the journey toward the upper world diminishing heat and pressure led to precipitation of dissolved contents. In former years we had no very definite conceptions of accessible depths, but the mathematical analysis of Professor Hoskins of the University of Wisconsin, combined with the geological observations and reasoning of President Van Hise of the same institution, has shown that cavities become impossibilities in the softer rocks at say 500 metres, and in the most resistant at or about 10,000. That is to say, under the irresistible crush of the overlying column, rocks hard or soft weld together into a solid mass. Circulating waters descending from the surface must be limited to these depths as the extreme.

But in the shafts, which are rapidly exploring lower and lower rocks in many localities and are changing inferences to observation, the experience of the miner has shown that in regions remote from recently extinct volcanic activity, the ground-waters end at a comparatively shallow distance. If while the shaft goes constantly downward the miner impounds the waters encountered at the upper levels, he meets no more below 1000 or 1500 ft. But the veins are known in many cases to continue certainly to three times this depth, and we have been forced to cast about for some other source than the rainfall for the subterranean circulations which have originally brought in the ores. Other waters have been suggested by two chief facts of observation. Whenever the volcanoes break forth in eruption, clouds and clouds of steam and other gases go violently into the atmosphere, and when the lava wells upward from the vent and pours abroad over the crater slopes and surrounding country, it steams for many months before it is exhausted of its dissolved vapors. Molten rock in the depths of the earth must be well nigh saturated with the pent-up gases, which are

only held in check by the surrounding envelope of the crust. We have even thought, with much reason, that the steam given forth by eruptive rocks in early stages of the earth's history has condensed as the oceans, and that thus the oceans have been derived from the volcanoes, not the volcanoes caused by the percolating oceanic waters, according to the more popular view.

The second significant point is that in almost all of our own mining districts where the operations are based on veins, eruptive rocks are a marked feature. In many, there seems no escape from the conclusion that they are in some way intimately associated with the formation of the veins which have come in as the end-product in their expiring activity.

Thus a large proportion of mining geologists and an even larger number of mining men accustomed to deal with the familiar phenomena of western ore deposits, have swung around to a belief in the waters from the eruptive rocks as the agents and vehicles of deposition. Even the prospector looks upon the eruptive dike as one of the best guides in his searching. When, therefore, a mass of molten rock charged with its burden of dissolved vapors and gases rises from the depths, and stops without reaching the surface, it slowly cools, congeals, and emits the vapors as the source of the mineral bearing waters which continue onward to the upper world. They start highly heated, under great pressure. They constantly cool as they go and the pressure diminishes. The dissolved minerals precipitate upon the walls of the fissures, quartz and gold in one region, silver ores with copper, lead, or zinc in another. Layer on layer they grow, until the water-course is choked or the fires below burn out, the steam pressure falls, and the circulation ceases. Water on the surface now begins its work, the rocks are worn away, the fragments of the vein roll down the mountain side and form the trail, which, catching the eye of the prospector, guides him to the outcrop.

But has geology made no broad and general contributions to human thought and life? Surely when we pause for a moment and reflect upon the changes through which our views of the earth and its development have passed in the century and a half now closing, we must admit that its influence has been enlarging and beneficial. Recall if you will the gross ignorance that prevailed about the age of the earth; the ridiculously insufficient conceptions of time; the idea that fossils were the sports of nature, entombed in the rocks to deceive or amuse mankind; the failure to grasp the plainest lessons of geological structure; and the absurd positive notions of the earth which once prevailed. Then we realize that into the mind of every man of even ordinary education and reading has come a flood of new light. Under the guidance of geology we see the long and stately panorama of the past unfold. Mountains rise and disappear; sea and land repeatedly change places. Majestic forces in orderly succession perform their work; and development, whose course we may follow and whose processes understand, is made clear before our eyes. We feel ourselves as it were upon some mountain summit looking ever away and away into regions beyond.

TIN ORE AT SPOKANE.

The discovery of tin ore at Silver Hill, southeast of Spokane, Wash., in 1907, has attracted considerable attention. Search for metalliferous deposits and for coal has been carried on at this place for several years, and prospects of silver-bearing galena had been noted. The tin-bearing mineral cassiterite was identified as such by Richard Marsh of Spokane in the summer of 1906, but prospecting for tin was not begun until March, 1907. The first authentic account of this discovery published outside of the local newspapers was prepared by A. R. Whitman of Spokane and appeared in the MINING AND SCIENTIFIC PRESS of June 1, 1907, by which time several carloads of selected ore had been mined and piled on the dump.

The discovery derived additional interest from the fact that no tin ore had previously been reported from the State of Washington, and Arthur J. Collier, one of the geologists of the U. S. Geological Survey, was detailed to visit the locality and examine the conditions. Mr. Collier spent several days early in the season in going over the prospects, and again visited the region in October to note the developments made during the summer. The information gained as the result of these limited investigations is embodied in a paper just published by the Survey as an advance chapter from Bulletin No. 340.

The region about Spokane is rich in natural resources. The city itself, the most important of eastern Washington, is about 18 miles from the Idaho State line and 90 miles south of the Canadian boundary, on the lines of the Northern Pacific, Great Northern, and Union Pacific railroad systems, and is the centre for extensive agricultural, lumbering, and mining interests. Vast expanses of rich wheat lands in the Palouse and Big Bend countries lie to the south and west, great forests of valuable timber are within 100 miles to the east, and the mines of the Coeur d'Alene district, the chief producers of lead-silver ores, are within 100 miles to the southeast. The Spokane river has a fall of several hundred feet and furnishes the surrounding country with water-power. Several inter-urban railroads radiating from Spokane are operated with power from the falls.

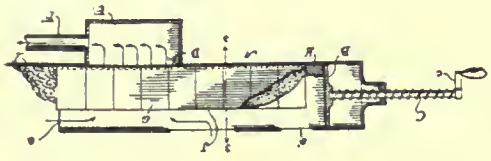
The geology of the Spokane region has not been studied in detail, but the relations of the rocks in the vicinity are known in a general way, and a brief statement of these relations is given by Mr. Collier. The rocks which seem to be the oldest in the region comprise a complex mass of gneisses and schists with many igneous intrusions of various kinds. These rocks form the mountains southeast of Spokane and contain the tin deposits.

The cassiterite found at Silver Hill is nearly black and is without definite crystal outlines. It is distributed through a nearly white, fine-grained rock, characterized by slight tinges of pink, in grains or masses ranging in size from that of a pinhead to that of a boulder several inches in diameter. Mr. Collier states that the developments at Silver Hill indicate that the tin ore is to be found in detached masses whose relations to each other cannot yet be determined.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

PROCESS OF ROASTING AND SINTERING ORES.—No. 882,518. Arthur S. Dwight and Richard L. Lloyd, Cananea, Mexico.

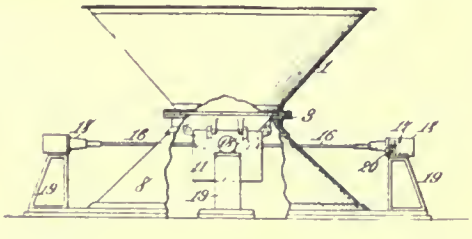


The herein described process of treating ores containing combustible elements to sinter them, which consists in moving a mass of the ore, firing it while being moved, beginning at the upper portions thereof, and subjecting the mass to a current of gas for supporting combustion, moving in a direction to cause combustion in the mass to progress in a downward direction, substantially as set forth.

PROCESS OF TREATING ORES.—No. 882,517. Arthur S. Dwight and Richard L. Lloyd, Cananea, Mexico.

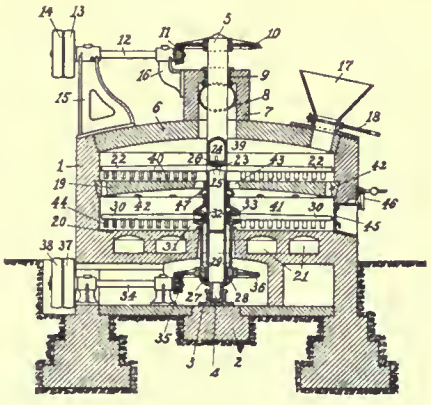
The process of treating metal-bearing ores in a mass of fine particles containing combustible elements and adapted to be sintered by internal combustion in the mass, which consists in igniting the combustible ingredients of the said ore, causing oxygen or a combustion supporting gas to pass to the interior of the mass of ore, thereby causing the combustion to extend from the place of initial igniting gradually into the interior of and through the mass, said mass having at all points substantially similar gas passages therethrough raising the temperature of the interior of the mass by such internal combustion to the point of sinter forming, and restraining from agitation or movement (in relation to the adjacent parts of the mass) those particles which are on the side where the gases or products of combustion escape until they have been sintered.

STOCK-DISTRIBUTER AND GAS-SEAL FOR METALLURGICAL FURNACES.—No. 883,044. Merrill B. Parker, Rockwood, Tennessee.



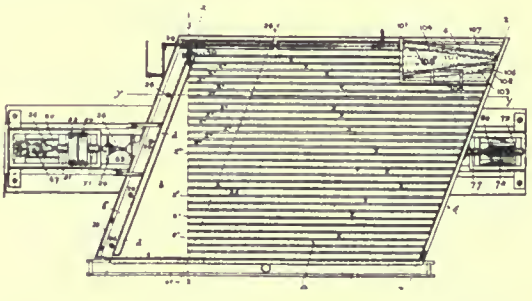
In a stock-distributor and gas-seal of the class specified, the combination with a receiving hopper and a furnace having a bell, of opposing pairs of doors hinged at their upper extremities to the lower portion of the hopper above the bell, and mechanism co-operating with the doors for either simultaneously moving the opposing pairs of doors inwardly at an angle of inclination, or opening one door of the pair and permitting the other to remain in inwardly inclined position, and also for alternately similarly actuating the opposing pairs of doors, the said mechanism including radially disposed straight piston rods rigid throughout their entire lengths, each piston rod being movably and directly attached to the outer side of one door below the upper hinged extremity of the latter, and fixed cylinders in alinement with the centers of the outer portions of the doors and having pistons therein to which the said piston rods are individually connected.

MECHANICAL ROASTING-FURNACE.—No. 882,730. Roman von Zelewski, Engis, Belgium.



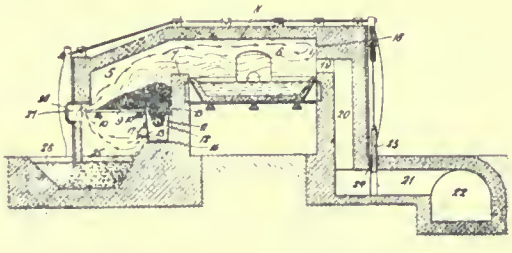
A mechanical roasting-furnace provided with a plurality of sets of rabbles, means for operating and for setting at rest one set of rabbles, and means for operating and for setting at rest another set of rabbles independently of the first-named set of rabbles.

ORE-CONCENTRATING TABLE.—No. 882,511. George E. Woodbury, San Francisco, California.



An ore concentrator having a concentrating table the surface of which has a riffled section, the riffles of which terminate on a line extending across the table and approximately at right angles to the lay of the riffles, and an unriffled or plain section beyond the riffles toward the discharge end of the table, this unriffled section being substantially triangular with its apex in close proximity to the uppermost riffles and its base coincident with the gangue discharge side of the table, the section being adapted to discharge concentrates along the whole of the concentrates end of the table, whereby the concentrates from the upper riffles are free to escape quickly after leaving the riffles, and those from successively lower riffles take gradually increasing paths of travel, and means arranged adjacent to the discharge edge of the table for feeding water to the said plane surface thereof.

FURNACE.—No. 883,057. Martin Van Buren Smith, New York, New York.



In a puddling furnace, the combination with a combustion chamber and means for evolving gases at a low temperature therein, of a puddling chamber adapted to receive gases thus evolved from the combustion chamber, means for supplying highly heated air from the combustion chamber to the puddling chamber in a condition substantially unmixed with the gases from the combustion chamber, and means within the puddling chamber to cause the mixture of the gas and air therein.

TUNGSTEN ORE PRICES IN GERMANY, 1902 TO 1908.

(Furnished by DeGolia & Atkins, San Francisco.)

The following table shows the approximate values of wolframite in Germany during the past few years. The price is given in dollars per unit of contained tungstic oxide (usually termed tungstic acid) per ton of 2000 lb., the unit being 1% or 20 lb. per short ton of 2000 lb. For instance, wolframite containing 60% (sixty units) tungstic acid would be worth $300 per ton when the price is $5 per unit.

Formerly scheelite was regarded as slightly less desirable than wolframite, and the price paid for scheelite has been from 50 to 75 cents per unit below that for wolframite. This difference arose from the fact that scheelite was considered more difficult to treat by the old crucible method of preparing tungsten; but for the modern method of reduction in the electric furnace scheelite is said to be fully as desirable as wolframite.

COMMERCIAL PARAGRAPHS.

N. D. Phelps has assumed the Pacific Coast management of the Power and Mining Machinery Co., Cudahy, Wis., and has established his office in 217 Sheldon Bdg., corner First and Market Streets, San Francisco.

The Tracy Engineering Co. of New York has secured the contract and started the construction of a 20-stamp combination amalgamating and concentrating mill for the Orange Blossom Mining & Milling Co., in southern California. This plant will be completed in 60 days.

Robert L. Bailie, president of the Golden Crest Mining Co., has placed a contract with the Moore Filter Co., and will shortly install at its mill in Deadwood, South Dakota, a Moore slime-filter having a capacity of 250 tons per day. The Moore process will be of their type 'A,' embodying many new features.

The Bristol Co., of Waterbury, Conn., has come under the control of William H. Bristol, whose inventions this company has been manufacturing since it was first organized in 1889. W. H. Bristol assumed active charge of the management of the business on March 28, and now owns the majority interest.

The Westinghouse Machine Co. announces that the receivers appointed Oct. 23, 1907, by the Circuit Court of the United States for the western district of Pennsylvania, were on March 31, 1908, discharged by the same authority. All of the matters which made a temporary receivership expedient have been satisfactorily arranged, and the company's position is greatly strengthened from every standpoint. All contracts made by the receivers for the sale of the company's product, or for the purchase of materials or merchandise, will be carried out as though made by the company's own officers. William H. Donner has been elected vice-president of the company, in direct responsible charge of all its activities.

BOOKS RECEIVED.

'Metallurgy of Tin.' By P. J. Thibault. Pitman & Sons, London. 250 pp. Price $4. This book is full of valuable information on all branches of the metallurgy of tin, especially as practised in Australia. The methods of assaying tin ores and furnace products are described, and also the methods of working placer deposits by dredging and sluicing. The reduction of ore is also described in detail. Much interesting and valuable information is obscured by the inferior printing of the reading matter and illustrations, while the poor presentation of the material makes it an unpalatable segregation of metallurgical statements rather than the lucid treatise which the author might have prepared. For sale by the Mining and Scientific Press.

'The Standard Handbook for Electrical Engineers.' McGraw Publishing Co. 1283 pp. Price, $4. This is the most complete handbook for electrical engineers that has been published. The entire field has been treated, in 20 sections, each of which was assigned to a specialist. The book is well indexed, and the numerous references to technical literature and excellent material make this a most valuable book of reference, which should be in the office of everyone actively engaged in electrical engineering practice. For sale by the Mining and Scientific Press.

'Lead Refining by Electrolysis.' By Anson Gardner Betts. 394 pp. $4. J. Wiley & Son. For sale by the Mining and Scientific Press. This book contains information resulting from years of study, experiment, and practical work of the electrolytic refining of lead bullion, which is now an established metallurgical process and one from which further developments may be expected in the future. The methods of slime treatment are also discussed in considerable detail.

'Simple Mine Accounting.' By David Wallace. 64 pp. $1. Published by the Hill Publishing Co. For sale by the Mining and Scientific Press. This book is intended for those who have had no chance to learn book-keeping. It is well adapted for the use of foremen and superintendents, being sensible and simple. It covers the ground satisfactorily, from vouchers, cash-books, and ledgers to stock and smelter records.

'Methods and Devices for Bacterial Treatment of Sewage.' By W. M. Venables. 236 pp. $3. J. Wiley & Sons. For sale by the Mining and Scientific Press. This subject is fully treated from the view-point of the civil engineer, and contains a full summary of the known engineering principles involved in the subject under treatment and a statement of the problems unsolved.

'The Engineering Index Annual' for 1907. Published by *The Engineering Magazine*. This is the sixth volume of an index now well known to technical men. Each branch of current engineering literature is classified, so that an individual article is easily found. Price $2.

CATALOGUES RECEIVED.

Beaudry & Co. have issued a booklet describing the Beaudry Champion power-hammer.

The Stromberg-Carlson Telephone Mfg. Co. has issued pamphlet No. 5, describing its Iron Clad Magneto telephone.

L. Vogelstein & Co. give the following figures of German consumption of foreign copper for the months of January and February, 1908:

	Tons.
Imports of copper	29,817
Exports " "	1,413
Consumption of copper	28,404

as compared with consumption during the same period in 1907 of 16,044 tons. Of the above quantity, 21,910 tons were imported from the United States.

Editorial.

OUR CONTEMPORARY at New York, *The Engineering and Mining Journal*, issues an excellent supplement devoted to the coal industry. The *Journal* is the recognized weekly authority on this subject.

IT IS ANNOUNCED that there will be a Mining Exposition in Madison Square Garden, New York, from May 25 to June 20. The United States Government and many of the States will participate by sending exhibits of their mineral resources.

BY TELEGRAM, we learn that the Mining and Metallurgical Society of America was organized at a meeting held on April 20 at New York. There is to be another meeting on the 27th instant. In our next issue we shall publish the constitution and by-laws.

WE ARE GLAD to state that Dr. T. Kirke Rose and Mr. H. Forbes Julian have become Special Contributors to this journal. These two distinguished metallurgists need no introduction to our readers. Dr. Rose's 'Metallurgy of Gold' and Mr. Julian's collaboration with Mr. Edgar Smart in 'Cyaniding Gold and Silver Ores' have made their names honored throughout the world of mining. Only recently our list of Special Contributors was strengthened by the addition of Messrs. Horace V. Winchell and John A. Reid, two geologists of recognized standing. The editor of the MINING AND SCIENTIFIC PRESS is proud to have the support of these leaders in the profession.

NAT C. GOODWIN said recently in a speech that he had "decided to go into the realm of minery." He should have said, not minery, but spoofery. It is a wide realm, with uncharted shores, dangerous reefs, tricky shallows, and lots of terrible pirates that scruple at nothing. And woe to the poor actor that wanders therein. Not that Mr. Goodwin is a bad actor; in that respect he is well enough, but in mining affairs he is either a knave or a fool. He has no right to allow his name to be placed at the head of a mining company, for in such matters he is wholly ignorant and the use of his notoriety as an actor in order to help the sale of stock is obviously to lure simple people into investing their money in ill-advised schemes.

RESORT TO a spiral tunnel by the Canadian Pacific railway to reduce the heavy grade on the main line up Kicking Horse canyon in British Columbia, announced in our correspondence from Rossland this week, recalls the fact that the originator

of this clever plan for overcoming the obstacles to railroad mountain-climbing was the late Mr. William H. Cilley, an American engineer. After long and costly efforts to find a way for the Peruvian Central railway on a feasible grade up the valley of the Rimac, the solution of the problem came as a flash of genius. Mr. Cilley turned into the mountain, lengthened the road by a spiral tunnel, and reduced the grade. The method was later applied for a like object in the St. Gothard tunnel in the Alps.

NEW DISCOVERIES are being made almost daily in Nevada, and while some of them may be ephemeral, others will probably prove the basis for important mining enterprises. We hear good news of Seven Troughs, Fairview, Jamestown, Jessup, Hornsilver, and Stimler, besides the overboomed camps of Round Mountain, Manhattan, and Rawhide. At Goldfield, the discovery in the Big Bend is important because it is three miles northeast from the bonanza zone and thus indicates an extension of the productive territory. At Rawhide there are 15 hoists at work and that means mining, which is more likely to uncover orebodies than the twaddle of actors and stockjobbers.

THE SEPARATION OF SLIME has always been a bug-bear in ore-milling. It has become one of the great problems in the way of the metallurgist since the cyanide process has attained such universal application. Aside from any emoluments it may bring, it is an honor to contribute effectively toward the solution of this vexing difficulty, and it appears that Mr. Horace G. Nichols has won claim to high consideration for his brilliant discovery, described in our columns elsewhere. So radical is the new fact here presented concerning the fall of matter suspended in water, that it has been asserted by Mr. R. Gilman Brown that "all facts and data in relation to the settlement of slimes might have to be reconsidered in view of the admissibility of the factor of retardation and the possibility of its removal" in the way pointed out by Mr. Nichols. The principle now for the first time recognized, has been utilized in several ways before, but never in so effective a manner, because the significant fact was not then understood. To Mr. Nichols came the inspiration of the interpreter, and the opening up of most important practical possibilities follow.

LABOR conditions on Douglas island, which is synonymous with the Alaska Treadwell mine, are improving. The town, immediately west of the mines, has held an election and this resulted in the victory of the 'town' ticket over the 'labor' ticket. The *Daily Alaska Despatch* congratulates its readers on their success in keeping municipal affairs free from labor strife. We second that. The Western Federation of Miners has been pursuing a dog-in-the-manger policy, unwilling to work themselves, and yet anxious to prevent others from accepting a job at Treadwell, where high wages are paid, where the mines are dry and safe, and where the employees are better fed, housed, and treated than almost anywhere in America.

Yukon Gold.

AT THE TIME of Mr. Lawson's advertising campaign we stated that a criticism of the technical features of this important undertaking would be postponed until the full reports of the engineers were available. This was only fair. If mining engineers cannot get fair criticism in the editorial columns of a professional paper, where then will they get it? Certainly not in the daily press, steeped in ignorance of technical matters, nor in the financial periodicals subventioned by various promoting agencies. Since we referred to the Yukon affair, we have received a letter from Mr. O. B. Perry, who is the chief engineer of the enterprise, for Mr. A. C. Beatty only confirms his colleague in a general way, not having data of his own wherewith to base a separate judgment, and as regards Mr. A. N. C. Treadgold, he performs the function of an enthusiastic promoter rather than that of a technical adviser. Mr. Perry's letter, appearing on another page, is welcomed, but the main purpose of it seems to be to combat the notion that "the properties have no value" and to emphasize the fact that a good deal of preliminary work and careful investigation have been performed at Dawson in behalf of the Guggenheims. Of this there never was any doubt in our mind, nor in that of others at all well informed, for Mr. Perry himself has an excellent reputation in San Francisco, and it was assumed that he would not incur so grave a responsibility without much forethought. The question is not as between worth or worthlessness of the Yukon enterprise but concerning the earning capacity of the heavily capitalized company that has been formed to exploit these gravel deposits. We do not ask whether the mining operations will be profitable, but whether they can repay the capital, and a reasonable interest, of a corporation organized with 3,500,000 shares of $5 each. Then we ask what return there will be on the $7.50 to $15 variously stated by Mr. Lawson to be the present worth of the stock placed on the market by that financial filibuster. But at this point we think it well to halt and enquire what responsibility is to be attached to the engineers as regards the issuance of the stock recently advertised in a campaign of misstatement. Mr. Beatty is so closely identified with the business dealings of the Guggenheims that he is likely to have known what was about to happen. If he did not we hope he will say so, if only to remove a blemish from his reputation for shrewdness in business affairs. His report in the printed statement now issued is no report at all, but a blank check to Mr. Perry, on whom professionally the entire responsibility rests; for, we repeat, Mr. Treadgold is to be classed as the promoter who originated the scheme, rather than an engineer qualified to pass an opinion upon it. As to Mr. Perry, we believe that he has been placed in a false position. Until the morning when he saw Lawson's flamboyant advertisements in the daily papers, he knew nothing of the scheme

to sell stock at an inflated price. This information does not emanate from him: as an engineer his first duty was to be loyal and we know enough of such matters to be able to emphasize the paramount obligation of a professional man to consider the interest of his client even at the hazard of his own reputation. But we decline to blame Mr. Perry in any way for the antics of Lawson or for the misuse made of his report. It is a sad fact that the mere mention of a man's name by Lawson in any of his pronunciamentos is damaging; if S. F. Emmons or James D. Hague were quoted by Lawson in one of his broadsides, the mere association would depress the character-stock of men of even such unquestioned reputation. Lawson is a pest.

From the report we are led to conclude that the enterprise was in no condition for presentation to the public and that the statements of Messrs. Beatty, Perry, and Treadgold, although dated on different days of the past month, were prepared in a hurry. Mr. Perry says that the "partial equipment" will be "practically completed" by the end of 1909, and it will not be until 1910 that operations at Dawson will be in full swing. According to Lawson's advertisement, Mr. Beatty appears to contradict Mr. Perry by saying that "the properties are fully equipped," but by referring to the printed report it is seen that Mr. Beatty said "*when* the properties are fully equipped." The re-arrangement of the paragraph indicates that this is no mere typographical error, but a willful misquotation. There is nothing in Mr. Perry's report that can be construed as an endorsement of the valuation placed upon the property by Lawson. In that report the gravel available for profitable mining is estimated as containing $50,000,000, from which a profit of $36,000,000 is to be won, and in default of a statement by Mr. Perry as to the total quantity of gravel we turn to Mr. Treadgold and find his estimate to be 137,000,000 yards, from which we get a working cost of 10 cents per yard. Turning to Mr. Perry's letter, appearing in this issue, we find that his total estimate is for 109,450,000 yards, having a gross value of $47,850,000 and a net profit of $37,500,000, so that here again the logical inference points to a cost of 10 cents per cubic yard. But this does not agree with the expressed statement that the cost of working is to range from 10 cents when hydraulicking the hill deposits to 32 cents when dredging the creek bottom. From these grand totals and general estimates we turn to the plain statement of Mr. Perry (in the printed report) that the Yukon Gold property contains 30,000,000 yards of creek gravel, containing $20,800,000, to be worked for $9,000,000, which is equivalent to a cost of 30 cents and a profit of 39 cents per yard. Then there are 35,000,000 yards of hill gravel, containing $11,250,000, to be extracted for $3,500,000, or a cost of 10 cents and a profit of 22 cents per yard. Thus we have 65,000,000 yards from which a profit of something over $19,000,000 is to be won. So far so good. Next come "probabilities and possibilities": these include 20,000,000 yards in the creek and 10,000,000 yards on the hill. In some way, partly explained but by no means clear, the total gross value climbs to about $50,000,000 and the estimated profit to $38,000,000. If Mr. Treadgold's figures are included, as stated in the printed prospectus, the confusion becomes intensified, for he speaks of 137,000,000 yards assured and a further probable 21,000,000, to be treated "at a later stage," and even this grand total of 158,000,000 does *not* include the Cariboo and Atlin properties, the yield of which *is* included in Mr. Perry's estimated profit of $38,000,000. All this shows that insufficient exact information is available at this time. A yardage that ranges from 95 to 158 millions, and a profit variously estimated at from $37,500,000 to $46,450,000, suggest that there are undetermined factors in the problem. Mr. Beatty endorses Mr. Perry's report, Mr. Perry believes Mr. Treadgold to be a "keen and careful observer," and yet the net result of their investigations is a mass of contradictory figures. The plain fact appears to be that exact data are not available at this time. A great deal of useful work and intelligent investigation have been in progress under the direction of Mr. Perry and he has done much toward solving the difficult problems presented by arctic conditions. He is deserving of credit for having devised new methods for overcoming the hindrances to cheap operation in frozen ground, and had he been given further time he could have made a report that would have hung together. It appears to be another case of an engineer's reputation being endangered by the exigencies of finance.

From this maze of conflicting figures we return to the plain statement that the Yukon property contains, assured and proved, 65 million yards capable of yielding a profit of 19 million dollars. In 1908 the profit is to be $800,000; in 1909 it is to be $1,500,000, leaving $16,700,000 still to be won. By 1910 the operations are to be in full swing and will yield a profit of about $2,500,000 for "a number of years to come." At this rate the $16,700,000 will have been realized in 7 years. Thus Mr. Perry suggests 9 years as the term wherein the assured resources will be exhausted. Anyone investing $17,500,000 (the capital of the Yukon Gold Company at $5 for 3,500,000 shares) today, in safe 5½% bonds, would receive in 9 years, with interest compounded, the sum of $28,332,500. Those who get 19 millions from the golden gravel at Dawson will receive each year a sum of money ranging from $800,000 at the end of 1908 and $1,500,000 at the end of 1909, to $2,500,000 thereafter for 7 years more. These annual profits if re-invested at 5½%, would yield $4,000,000 in the 9 years, and this added to the $19,000,000 makes $23,000,000, which is about $5,000,000 less than the sure gain accruing from the investment of $17,500,000, as above explained. Thus the investor pays $5,000,000 for the "probabilities and possibilities," which will not be forthcoming in the first nine years but may become a feature at a later stage. And we are quite ready to accept Mr. Perry's professional opinion that those "probabilities and possibilities" are worth $5,000,000 more than the money paid for the certainties. Therein lies the sport of mining, and also the great gains made by the adventurous. But not on a basis of twice what the property cost. According

to the published report of the Guggenheim Exploration Company there has been invested in the Yukon properties, and their equipment, the sum of $8,220,000. This was done on Mr. Perry's advice and he validates that advice when he states to Mr. Daniel Guggenheim that there is $19,000,000 assured, to be extracted in 9 years, with "probabilities and possibilities" that are problematical and uncertain, of course, but yet capable of doubling the final return of money. On an investment of 8 millions to return 19 millions in 9 years, Mr. Perry gave the Guggenheims an investment yielding 20.2%, not to mention the aforesaid "probabilities and possibilities." Mr. Perry is a good adviser to his clients, but that same advice when twisted and distorted by the hand of Lawson becomes illogical and unconvincing to the point of absurdity. On Mr. Perry's advice the Guggenheims invested 8 millions on the Yukon, then the Guggenheims capitalized the enterprise for 17½ millions, and finally Lawson shrieks that it is worth anyway from $26,250,000 to $52,500,000. Perry ascertained the actualities, the Guggenheims capitalized the possibilities, and Lawson distributed the eventualities.

JUST as we go to press, the editor is in receipt of the following telegram from Mr. O. B. Perry:

"Find on investigation that table prepared in my absence to accompany my letter reference Yukon, was compiled from a cancelled report and that figures are absolutely incorrect and worthless for purpose intended. Please destroy table and take any figures you care to use from the printed report. Regret mistake, which was due to my enforced absence from office account sickness." This is dated April 23, at New York. In order that no injustice may be done, this telegram is given the fullest publicity, but, as a matter of fact, it will be found that our comments have little to say concerning the table which was transmitted in error. Mr. Perry's letter, which appears under 'Discussion,' was in print before his telegram arrived and it was impossible to comply with his request. Unfortunately, the letter itself does not refer to the table in such a way as to identify it or to suggest the error in transmission.

The Engineer and the Economic Geologist.

BROAD scientific generalizations are always useful when they emanate from men who have helped to build up science, who know the inner framework of the structure, and the character of the foundation on which it rests. They enable the learner to avoid errors and loss of time, and to fix attention upon the points that need elucidation. Just such a helpful and stimulating document is the recent presidential address of Mr. Waldemar Lindgren, before the Geological Society of Washington, the major portion of which we re-print in this issue. Mr. Lindgren speaks by authority of rich experience in the detailed study of the greatest mineral districts of two continents. He has helped unravel their geologic story, and he has been one of the foremost men of the time in interpreting the phenomena of ore genesis. Mr. Lindgren's conclusions carry the greater weight because of his freedom from radical views. The enthusiasm of the deductive scientific speculator is excellent, chiefly because stimulating. It may also lead to a short-cut in reaching a comprehension of things that might otherwise have remained long hidden. But the inductive reasoner is the safe guide, and such is Mr. Lindgren in the great field of economic geology. The degree of caution, in the light of wide first-hand acquaintance with facts, displayed by his attitude toward classifications of ore deposits, challenges attention. When geologists knew less they were fruitful of elaborate schemes of classification. The text-books have been full of them. But our knowledge of geochemistry, of metamorphism with its startling physical as well as chemical influences, of magmatic differentiation, and of other conditions beset with difficulty for the collector of data, has so grown, and so complicated our view, that we find Mr. Lindgren siding with those who will not attempt to make final subdivision beyond the classing of all deposits as either syngenetic or epigenetic, that is, those formed contemporaneously with the enclosing rocks, and those introduced subsequently. This relieves the student from embarrassment, for the tendency of the young geologist is to fix his facts each in some proper category, and the wider his main sub-divisions the more free and open to revision do his data remain.

We think Mr. Lindgren expresses a professional bias, however, which has been a product of unconscious growth among economic geologists, following the enormous expansion of the subject in recent years. Economic geology has not become a department of science, but a kindly link between the plain geologist on the one hand, whose concerns are chiefly with physics and chemistry, paleontology and stratigraphy, and volcanology, and the engineer and industrial worker on the other hand, whose concerns are to obtain as quickly and cheaply as possible a maximum quantity of useful metallic wealth for the benefit of the world. It is not just to a profession which demands such varied training in high degree as that required by mining engineers to insinuate that its members are merely blessed "with sufficient geological training to appreciate and describe what they see." The work of men like Rossiter W. Raymond, Clarence King, James D. Hague, and a goodly company of younger men whose contributions have appeared in the *Transactions* of the American Institute of Mining Engineers and elsewhere, has been far more than descriptive—it has been constructive in the best sense. Cleavage between the mining engineer and the economic geologist should not in fact be drawn. They should recognize themselves to be of one fraternity, in the interests of efficient co-operation as specialists within the same profession. We believe it not unjust to assert that the references made by officers of the Geological Survey and other professional geologists, to the investigations carried out by mining engineers, have occasionally been lacking in the generosity that marks great scientific men. Volunteers are as patriotic as regulars, and occasionally as good soldiers.

Personal.

JAMES D. HAGUE is here.

J. R. FINLAY is at Joplin.

J. H. CURLE is in Bolivia.

NEWTON B. KNOX is at Paris.

J. W. MERCER is at Mexico City.

H. C. HOOVER is about to go to Singapore.

MARK L. REQUA is on his way to New York.

LEWIS T. WRIGHT has returned from London.

F. J. SIEBERT, of Goldfield, was here this week.

ALLEN H. ROGERS, of New York, is now in Mexico.

F. H. MOBLEY, of Denver, is now in Sonora, Mexico.

A. J. BENSUSAN has returned to London from Brazil.

EDMUND JUSSEN, of Salt Lake, is visiting Blair, Nevada.

F. L. RANSOME was in New York for a couple of weeks.

H. W. TURNER has been examining the Monterey coal mines.

R. B. WILLIAMS is with the Miami Copper Co. at Globe, Arizona.

FRANK H. PROBERT has returned to Los Angeles from Globe, Arizona.

W. J. LORING arrived in San Francisco and then went on a visit to Angels.

ERNEST H. DENICKE has returned to San Francisco from southern Nevada.

JOHN H. MARKS has returned to Denver from the Altar district, in northern Mexico.

F. W. OLDFIELD of Los Angeles was in San Francisco on April 20, on his way to Vancouver.

W. F. HARRISON has been appointed manager for the Indé Gold Mining Co. in Durango, Mexico.

J. W. BRYANT, superintendent for the Tyee Copper Co., has returned to Victoria from Mexico.

WALDEMAR LINDGREN was in San Francisco and has gone to inspect some new Nevada goldfields.

ROY H. CLARKE has removed his office from the Columbia building to the Hyde block, at Spokane.

JOHN W. FINCH is traveling in Switzerland and Italy. In July he will open an office in New York.

H. GRAFTON VERCOE, son of the late H. B. VERCOE, is now living at Camborne, in Cornwall, England.

OLIVER B. FINN, of Colorado Springs, is now at Tucson, Arizona, where he is examining some copper mines.

G. McM. ROSS has just returned to San Francisco from Nevada, where he has been examining several mines.

W. H. KNOWLES, formerly in Colorado, now residing at Los Angeles, is examining mines near Phoenix, Arizona.

A. P. ROOT and LUCIEN H. NORTON have formed a partnership and opened an assay laboratory at Silverton, Colorado.

D. M. MUNRO has been appointed manager of the El Favor mine in the Hostotipaquillo district, State of Jalisco, Mexico.

LLOYD WOMBLE has joined the staff of Chas. Butters & Co. and sails from San Francisco on April 25 for Devisadero, Salvador.

CONTE DE TRISTAN, mining engineer to the Staffer Chemical Co., has been visiting the Summit mine, in Shasta county, California.

H. FOSTER BAIN, H. V. WINCHELL, and GEORGE H. ASHLEY have become associate editors of *Economic Geology* with JOHN D. IRVING, the editor.

The firm of PEMBROKE & RIGBY, of Salt Lake, has dissolved, and EARL R. PEMBROKE has established an office at 54 W. 2nd St., Salt Lake City.

BULKLEY WELLS was in San Francisco on his way to southern California. He is still suffering from the shock to his system caused by the explosion.

A. N. CLARK, formerly of the editorial staff of the *Engineering News*, has been appointed superintendent for the Arizona-Nevada Gold Mining Co., near Luning, Nevada.

General Mining News.

ALASKA.

(Special Correspondence).—Nolan creek, a tributary of the Koyukuk river, has been developed this winter, and very rich diggings have been found. Nolan and Murray have found a pot-hole on their Discovery claim which is stated to have produced $128,000. The bedrock is 100 ft. deep in places and large nuggets occur.——Good pay gravel has been found on Smith and Vermont creeks and all the tributaries of the Hammond river. Nolan creek is 60 miles from the Chandelar.——A new pay-streak has been found two miles west of Nome. It is about 35 ft. below sea level and crosses the present shore line. It was discovered by J. Brower and occurs in frozen ground that extends under the Bering Sea. The strike at Fairbanks still continues and the operators are importing non-union laborers. Soldiers have been ordered from Fort Gibbon to the Tanana. ——Several business men are leaving Nome to go to Anadyr, Siberia, where a stampede will probably soon occur. A line of steamers will be put on this summer from Seattle, calling at Nome. Rich quartz and placer deposits are reported. The Governor of that district in Siberia has given a warning that no person will be allowed to land who has not provisions for one year, or its equivalent, that is, about $300 or 700 roubles. The steamer Corwin from Seattle is already announced to leave Nome about June 15 for Anadyr. ——At Nome work is actively progressing. Fifteen steam hoists are operating on Center creek, and 47 other hoists are working adjacent districts. Over 100 claims are taking out pay-gravel and the snow is deep and the prospects for plenty of water during the summer are excellent.——It is stated that a rich gold discovery has been made on the Innoko river adjacent to the Kuskokwim district. To go to this district prospectors go 400 miles up the Yukon to Yukon slough. This is followed 40 miles to the mouth of the Innoko river. From the mouth to the Indian village of Diskakat is 150 miles by water or 75 miles by winter trail. This is the head of navigation for boats over 20 tons. The diggings are about 125 miles farther up. A new route will soon be opened, leaving the Yukon 155 miles south of Fort Gibbon. From this point a trail is being cut, which will reduce the distance to 100 miles from the Yukon river to Innoko.

Nome, March 15.

ARIZONA.

COCHISE COUNTY.

The new power-house and hoist at the Copper Queen is nearly finished.——At the Calumet & Arizona smelter the construction work on the enlargement of the plant is making good progress. The frame for a new converter has been completed and excavations are now being made for moving the four converter stacks in operation at this time from their present position to the south side of the smelter building. When the converters are moved they will be connected with the new smokestack already completed. Then the work on the new furnace can be started, as the material has already arrived. During the last year the C. & A. has done a large amount of construction work at their new plant, including a new power-house, a new machine shop and a new blacksmith shop. In the new power-house all the machinery which will be required for the enlarged plant is in place, with the exception of a blower engine for the No. 7 furnace. The old wooden ore-bins are now being torn away so that the new blast-pipes can be placed in position. The old bins have not been used except for storing surplus ore since the high line was constructed more than a year ago. During the present week there has been an increased quantity of coke coming in from the ovens. This coke has been piled along the side-tracks, where it will be picked up by the steam shovel when required for the furnaces. The C. & A. has never carried a large amount of surplus ore, but at the present time more ore is coming from the mines at Bisbee than can be handled in the furnaces, so that the surplus piles are growing larger. Five furnaces are being run to the limit of their capacity, which is 300 tons each. When the present plans of enlargement have been completed the C. & A. smelter will have a capacity of more than 3000 tons daily.——The Great Western group of claims, a few miles from Gleason, has been bonded by T. W. Young, and development work has been begun.

GILA COUNTY.

Ore has been found in the north cross-cut on the 12th level of the Gem mine of the Globe Con. Co. at about 750 ft. from the shaft. The development of the vein at this depth will determine the future of the mine.

MOHAVE COUNTY.

(Special Correspondence).—The Gold Bug mine, which up to a few years ago produced considerable gold ore of a shipping grade, and was then abandoned until recently, is being overhauled for work again. There are over 250 ft. of underground workings from the 300-ft. level, which have caved badly, filling up the drifts with impassable piles of débris, which are being removed, and the work of timbering up the main shaft is also under way. The mine is situated in the White Hills district, about 30 miles north of Chloride, the terminus of the Utah branch of the Santa Fe Pacific railroad, whence timbers are now being hauled by wagon to the mine. The work of cleaning out the old workings will require about 60 days, when the work of sinking the shaft to a depth of several hundred feet below its present level will begin.——The group of mining claims belonging to Buchanan and Chittenden, situated five miles south of Kingman, at the edge of the Malapai belt, has passed into new ownership. A. L. Darbyshire is the purchaser. The claims are known as the Abe Lincoln group, and is in easy hauling distance to McConico station on the Santa Fe Pacific railroad. An agreement was made as one of the terms of the sale that a shaft would be sunk to a depth of 200 ft. at once. A company will be floated to raise capital to carry out the plan of development, but A. L. Darbyshire will arrange for commencement of work before leaving for the East.——Arrivals here from the Gold Road mine in San Francisco district report the opening up of a good shoot of ore. The new find was made on the 500-ft. level, where a body of high-grade milling ore was encountered and the work of opening up new stoping ground immediately began. ——San Francisco capitalists have a mining engineer examining the Sheeptrail mine in the Union Pass district with a view to purchasing. The claims in this group have veins which are large but of low grade. The Catherine claim, which lies 6 miles west of the mine, at one time produced considerable gold and silver. All the old workings in both camps are in a good state of preservation.——A fine showing of ore was made last week in the Tyro group of mines in the Signal district, samples of the new ore running more than 50 oz. silver per ton. The discovery was made in a new shaft being sunk on the north end of the group and was the first silver ore found.——Work is being systematically continued on the 500-ft. shaft of the Victor mine two miles west of Gold Road.——A 30-ft. vein of ore, running $10 in gold and silver, is being worked on a claim situated in the south end of the Wallapai mountains, about 20 miles east of Kingman. The property belongs to W. Brown, S. Settle, and F. Brown, who are endeavoring to procure means to install reduction works and develop the property.

Phoenix, April 18.

YUMA COUNTY.

The Colonial Mining Co. has started smelting at its mine 12 miles north of Quartzsite. The new furnace is of 30 tons capacity. The shaft is being sunk from 500 to 1000 ft. and rich cinnabar ore has been developed. A new rock-breaker has been put up. C. Dennis is superintendent.

CALIFORNIA.

CALAVERAS COUNTY.

The Melones Mining Co. resumed work on March 1, on the basis of leaving the collar of the shaft or adit at 7 a. m. and working until 4:30 p. m., with 30-min. interval for lunch. At the surface, the shift is 10 hr., with 30 min. for

lunch, except machine-tenders, who work 11 hr. F. Langford is superintendent.

EL DORADO COUNTY.

At the Martin mine in the Grizzly Flat district, the shaft has reached a depth of 50 ft., but sinking has been discontinued owing to an excessive flow of water. A drift is now being driven to the north and about 150 tons of ore have been extracted for a test run, which will soon be made at the Mount Pleasant mill.——Development work is progressing well at the Prevolcanic mine at Pacific, and a good gravel channel has been found.——The Gold Hill mine has been sold to T. H. & N. Douglas. A large quantity of low-grade ore is on the dump. A mill will soon be erected.——A two-stamp mill is being put up at a quartz mine near the Alpine. The mine is leased by Gray and Coster, and a shaft sunk 50 ft. has encountered a shoot of rich ore.——A find of rich ore has been made in the Martin mine near Grizzly Flat.——A test run is being made with the five-stamp mill on a body of ore recently found in the Stillwagon mine.——A body of rich gravel has been found in the Gignac mine at Texas Hill. The ore has been tested by a mill run, and the mill will now be moved to a more convenient position.

NEVADA COUNTY.

(Special Correspondence).—Good ore has been opened up in the winzes at the Pennsylvania mine. The vein is strong and of good grade. The mill is running steadily. Bennett Opie is superintendent.——At the Gold Mound a 6-ft. vein is being developed by a drift from the bottom of the shaft. The ore is a good milling grade with occasional rich bunches. H. P. Dennis is superintendent.——Limited developments are under way at the Aurura. Sinking will be resumed in the near future. Harry Skewes is superintendent.——Preparations are being made to commence work on the Sunflower mine during the coming summer.——Extensive development work is going on at the Kenosha. The shaft is going down steadily. Good ore has been blocked out on the 300 level.——Three shifts are sinking the shaft at the Murchie mine from the 1000 level. The men recently employed in the work demanded $3.25 per day and were at once discharged. A new crew was put to work on the old scale, $3 per day. Labor is plentiful and the company is in a position to obtain all the men needed.——James A. Fly and associates have bonded the Marcotte mine and intend to work it on a comprehensive scale. The new five-stamp mill is running steadily.——Martin Vanberg has located the West Arctic claim in the Washington district.——The lower adit at the Plumbago mine will be extended to a distance of 5000 ft. It is now in about 3000 ft. Heavier machinery will be installed at the property.——At the Champion the new winze-shaft is going down steadily. In the lower workings considerable ore is being developed.——A large force is working at the Mountaineer and good ore is being developed.——The Golden Gate mine is working with a small crew.——At the Sultana group all the work is being carried on through the Presscott Hill shaft. Extensive orebodies have been developed and the property is looking well.——At the Yuba mine, near Maybert, arrangements are being made to operate the property on a large scale during the coming summer. The working force will be largely augmented and developments energetically pushed.——It is reported that the Giant King mine will be worked extensively during the summer.——The coal deposits in the eastern end of the county are attracting attention. A Nevada company was recently organized to prospect the district.

Grass Valley, April 20.

Good milling ore is being extracted from the Gold Mound mine on Deadman's Flat. The vein is about 6 ft. wide and of good milling grade.——Development work will soon be resumed at the Sunflower.——The Plumbago power-plant is to be moved up to the mine and more machinery will be installed. The lower adit is to be driven 1100 ft. farther. The machinery at the present power-house has been offered for sale.

Rich gravel is being extracted from the Posey Canyon mine. A cross-cut has been driven 60 ft. in the gravel, but the vein-rock has not yet been encountered. At present enough water is obtained from the adit, but soon water will be brought from the Excelsior ditch. The mine is owned by local capitalists.

The Serins mine, owned by Ole Helgeson, situated on Canyon creek between the Mountain View and Arctic groups, has been bonded to E. A. Work and H. Eckhardt. The mine is developed by an adit 300 ft. long, and a raise, giving a depth of 200 ft. on the vein. It is stated that a compressor and a 10-stamp mill will soon be erected.——The Neversweat mine in Willow valley will resume work about June 1. A contract has been let to cut mining timbers.

SAN BERNARDINO COUNTY.

The new hoist for the Quartette shaft was installed last week and the shaft is being sunk with three shifts at work.——The mill for the Big Chief Co. is now on the ground and the erection of it is started. The Quartette will also

Map of Northern California.

build a mill as soon as water is developed on the property.——The Big Chief lease is sinking with four feet of $50 ore in the shaft, and a vein has been found in the adit which is being driven from the west side of the mountain. The vein is two feet wide and is of good milling grade. The upper adit is in 130 ft. and the vein is now being cut, the ore being about $20.——The Sloan lease is working in 30 ft. of ore, a portion of which averages $50 per ton. Nearly 300 sacks of high-grade ore is now piled on the dump, and the lessee is preparing to make a shipment. After cross-cutting three feet from the 50-ft. shaft, which was sunk 30 ft. from the mouth of the adit, the lessees on Piute Belle No. 1 broke into four feet of good milling ore, averaging $25 per ton. Andrews & Marsh are the lessees of this block.——J. D. Goodwin has made a rich find on the Sunrise. At a depth of 50 ft. a cross-cut was run last week, and five feet of $30 ore is showing in the face. The Sunrise is a mile and a half from camp.——The Hart Con. Mining Co. will begin operations next week. The company owns the northern extension of the Oro Belle group, where Hart & Hitt made their original strike. The adit on Oro Belle No. 1 has reached a distance of 125 ft.——Two carloads of ore are now on the dump at the Stampher lease. At a depth of 50 ft. the lessee is driving in the vein. The ore averages $21 per ton, and as work progresses the ore-shoot has every indication of being large.——The Twin Peaks Co. are beginning operations next month on an extensive scale. A hoist and compressor will be installed and a double-compartment shaft will be sunk 200 ft. The Four Tramps lease on Twin Peaks have opened up an immense body of medium-grade ore, averaging $25 per ton. A hoist will also be installed at this lease.

PLUMAS COUNTY.

Active operations will soon be started by the Newton Mining & Development Co., which owns property on Coquette creek, and in Gravel range in western Plumas and Butte counties. The ground will be worked with a steam scraper. S. J. Norris is superintendent.

TRINITY COUNTY.

A five-stamp mill will be erected at the Leibbrandt mine on Rattlesnake creek beyond New River and Canyon creek, at an elevation of 6000 ft. The mill will be hauled from Redding to Coleridge, a distance of 80 miles, and then packed 25 miles over a rough trail. The mine is situated in one of the most remote parts of Trinity county.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—On an average 100 tons of mill ore is being treated daily at the Capital concentrator. Shipments of smelting ore are also being maintained, about 50 tons being sold each month. It is reported that within the near future another unit of 100 tons will be added to the milling plant, as the original plans called for a total capacity of 1000 tons at the concentrating works. Over 100 men are now employed in the mine and mill, but W. M. Cooper, the manager, expects to increase the force soon. ——It is believed that connection with the Seven-Thirty shaft workings in the raise being carried from the west Phillips drift run from the Burleigh adit, will be made some time during the coming week. There remains to be broken about 30 ft. of ground, and great care is being exercised to avoid danger to life and property. Drill-holes are kept 10 ft. ahead, as the old levels are filled with water. The Pelican mill, with a capacity of 250 tons per day, is in readiness to be started, and the Burleigh M. & L. Co., which has been performing this work under privileges of leasing any ground in the Seven-Thirty workings that is desired, is making ready for a more active campaign of development. The aerial tramway running from the Seven-Thirty dumps is practically completed, while the one running from the Pelican dumps is in operation. The two tramways have a capacity of 300 tons per day.——The Mendota mill is running night and day. For the present custom ore is being treated. B. J. O'Connell, leasing on the upper Frostberg, is shipping 100 tons per week, the product being lead and zinc. This lessee is stoping upon an orebody that is from 2 to 5 ft. wide.——A. Thoman, leasing on the Gold Dirt, is marketing from two to three carloads of smelting ore weekly that brings a settlement of 6 oz. gold per ton. The milling ore is being treated at the Empire mill and assays $50 per ton after concentrating from four to five tons into one.——Courtney Howard & Co. of Lawson have taken a lease on the Dictator mine, situated on Columbian Mtn. Driving is progressing and a streak of high-grade ore is being followed that measures from 2 to 4 in. across. The last mill run from this mine brought a settlement of 2000 oz. silver per ton, the ore having been mined in close proximity to where the present lessees are at work.——The Sceptre adit is to be advanced 400 ft. to intersect the Sunburst Extension vein. At that time a raise will be carried 370 ft. to connect with the Sunburst adit. The compressor and other machinery is expected to arrive in a few days, at which time machine-drills will be brought into use. Other work is being planned by the manager, C. H. Poirier, and the working force is being increased almost daily.——Early in May the cross-cut, started to intercept the 500-ft. level of the Shively shaft workings, will reach the objective. At that time the old workings will be drained, facilitating the exploration of a vast area of virgin territory. B. J. Martelon, the superintendent, states that if the reserves of low-grade ore are sufficient, a modern concentrating plant will be erected.——The Vesper group of claims in East Argentine, is being developed energetically. Cross-cutting is under way for the cutting of the Vesper, which should be reached, according to surveys, within the next 40 ft. The Vesper produced some high-grade ore from surface workings. W. M. Graves is in charge of the work.——The Lost Treasure mine on Columbian Mtn. is making an excellent showing. Driving is in progress upon a 4-in. streak of 900-oz. silver ore. Occasional shipments are being maintained. W. Cramer is owner and operator of this mine.——Operations at the Joplin M. & T. Co. holdings are being continued vigorously. A streak of ore is being followed on the Gambetta vein that measures from 12 to 18 in. wide, and average assay 64% lead and 50 oz. silver per ton are contained, as has been ascertained from recent shipments.——It is reported that the Centennial mine on Leavenworth Mtn. has been transferred to S. Peacock, representing a syndicate of Chicago capitalists. The water is now being lifted from the fourth, fifth, and sixth levels.——Seven pounds of ore taken from the Tol Reynolds on Alpine Mtn. was reduced to bullion at the local sampler a few days ago and a retort of 2½ oz. pure gold was secured. Homer Davenport is the owner of this mine.

Georgetown, April 13.

GILPIN COUNTY.

The Greater Canada Mines Co. has been incorporated to operate in the Russell district.——The station for the hoisting plant in the workings of the King Bee Co. in the Newhouse adit is completed and ready for the installation of the hoist, which is to be used in the sinking of a winze below the adit level.——A lease and bond has been taken on the Missouri mine in Russell gulch by T. W. Boyd of Idaho Springs. The shaft is being unwatered. There is now 150 ft. of water in the shaft, which is 400 ft. deep.——A force of 25 men is employed at the Fontenac mine at the head of South Willis gulch in the Russell district, and considerable milling ore will be shipped to the Black Hawk custom mills.

SUMMIT COUNTY.

E. G. Tuttle, the manager of the Colorado Gold Dredging Co., operating on the Swan river about five miles from Breckenridge, has recently completed two dredges and they will be in operation at full capacity by May. Each dredge will have a daily capacity of 3000 yards.

IDAHO.

BLAINE COUNTY.

(Special Correspondence).—The Eureka Development Co., Ltd., held its annual meeting in Salt Lake City, Utah, in February, when the following officers were chosen: president, W. A. Wilson; vice-president, A. C. Ellis, Jr.; secretary, Causten Brown. These, with E. B. Critchlow and Henry Eiseman, constitute the board of directors. The company's mine is at Bullion, seven miles west of Hailey. Operations were suspended last November, after having reached a depth of 340 ft. on the incline, with a level in ore running east from it, exposing the main ore-shoot, which is 110 ft. long. Work was resumed in January, 1908, and sinking on the main incline has been in progress since starting up. Almost an additional 100 ft. has been sunk. The shipping ore averages about 55% lead and 65 oz. silver per ton. Electric power for hoisting and operating the concentrating mill will be installed. The mill may be started about May 1. W. A. Wilson has been directing operations here for some time.

Hailey, April 16.

IDAHO COUNTY.

Some rich ore has recently been found on the Snowstorm claim on Red river owned by J. Coverly and R. W. Pittock. ——The Umatilla mine has been sampled by J. H. Jones. This mine has a large body of low-grade ore. This has been developed by a drift 400 ft. in length and nine cross-cuts. The orebody is 80 ft. wide. The main adit is 772 ft. long, striking the orebody 628 ft. from the portals and at a depth of 240 ft. It is stated that a railroad will be built into the Seven Devils country by the Copper Butte Milling Co., which holds a lease for 10 years on the Peacock copper mine.——Work has been resumed on the Champion Copper Co.'s mine. A contract has been let for 100 ft. of work to J. I. Johnson of Wallace. An upper adit has already been driven about 800 ft. and considerable cross-cutting has been

done, giving a depth of 300 ft. and showing a vein about 25 ft. wide carrying some rich copper ore. The new adit has been driven about 70 ft. and has reached the vein, which carries some high-grade copper ore with about $10 per ton in gold.——The adit on the Buffalo mine is in 300 ft. A contract has been let for 1300 ft. of work, and the vein should be struck at 900 ft. from the portal. The vein has

A Prospect in Nevada.

been developed on the surface by a 30-ft. shaft. The new adit will give a depth of 600 ft.——A creosoting plant is being erected jointly by the Bunker Hill & Sullivan Co. and the Government Forest Service at Wardner. The plant is almost completed. A 6-ft. cylinder is being constructed, having a small steel track on the bottom. The timbers will be loaded on handcars and pushed, car and all, into the cylinder. The creosote will be turned into the cylinder until full, where it will be allowed to remain from 6 to 8 hr. The liquid will then be drawn off and the timbers will be ready for use.

The litigation between the Hercules and Ambergis mines in connection with the adverse suits between the Anna and Ambergis claims and between the Rattler and Little Chief claims, has been settled and the Hercules, in consideration of a stock payment has agreed to give a deed to the Ambergis company for all of the ground conflicting with the Ambergis claims.

NEVADA.

ESMERALDA COUNTY.

The recent discovery of rich ore at the Great Bend mine in the Diamondfield district is proving to be important. The lessees have developed an ore-shoot for a distance of 125 ft. on the 300-ft. level. A winze has been sunk 50 ft. in ore. ——Rich ore is still being extracted from the Rogers-Syndicate and Little Florence leases. The Rogers-Syndicate is extracting ore from two deposits about 25 ft. apart. The shipments from Goldfield mines last week were higher than any made during a similar period since the labor troubles. The total shipments were 1870 tons, valued at $193,855. The average value of 820 tons shipped to the Western Ore Purchasing Co. was $175 per ton. The shipments from Tonopah from April 8 to 14 were as follows: Tonopah Mining Co., 3314 tons; Tonopah Belmont, 1213; Tonopah Extension, 99; Tonopah Midway Co., 293; McNamara, 99; Tonopah Mining Co., 98 tons. Total, 5116 tons.

LINCOLN COUNTY.

A shipment of ore is being made from the Deberry and Megede lease on the Boston mine to the New Era mill.—— The New Era Mining Co. will start development work on the American Girl group, which adjoins the Esther mine. ——Machinery for the small smelter to be erected at Rich Hill by the Santa Barbara-Searchlight Mining Co. is due to arrive shortly. Roads are being built and excavations for the foundations are being made.

NYE COUNTY.

Rich ore has been found on Little creek, 12 miles north of Round Mtn. The discovery was made by prospectors who have obtained a lease from the original locators. It is stated that the vein assays $900 per ton for 12 in. and $10 per ton for two feet.——A rich strike is reported from Manhattan. The Shea lease on Union No. 9 has encountered high-grade ore. A 3-in. streak is said to assay $2 per lb. and an 18-in. vein of $200 ore is being extracted.

UTAH.

JUAB COUNTY.

The hoisting engine at the Raymond-Illinois mine broke last week and the cage and cable fell to the bottom of the shaft. Nobody was hurt, but the mine will be shut down until repairs can be made. J. C. Sullivan is manager.—— The sinking of the main shaft at the Little Chief mine is being continued. The shaft is 1000 ft. deep and will be sunk to 1500 ft. Development will be continued on the 1000-ft. level while sinking progresses.——The Grand Central mine will start again on May 1, and a shipment of ore will be made to the new Tintic smelter.——The new smelter at Silver City is progressing rapidly and ore will probably be received after May 15. W. L. Mangum is manager. The plant will be operated by electricity and a power line is being built into Tintic from American Fork canyon. It is expected that smelting can be begun by June 1. In addition to the work being done upon buildings, furnaces and other equipment of the smelter, a large force of men and teams is now grading for sidetracks.

CANADA.

BRITISH COLUMBIA.

Following is the tonnage of ore shipped from and crushed at the mines of Rossland for the week ending April 11, and for the year to same date:

Mine.	Week.	Year.
Centre Star	3,320	49,918
Le Roi	1,435	25,169
Le Roi No. 2	595	9,013
Evening Star	....	428
Iron Horse	....	38
Blue Bird	....	30
Totals	5,350	84,596

At the smelter of the Consolidated Co. at Trail there was received during the week 6150 tons. Besides that from Rossland, other shipments were as follows: Rambler-Cariboo, 66 tons; North Star, 71; Cerro Verde, 9; St. Eugene, 563; Whitewater, 43; Eva, 23; Snowstorm, 468; Silver Cup, 33; First Thought, 294; True Fissure, 32 tons. At the

The Miller Lease at Rawhide.

Granby smelter at Grand Forks 21,063 tons of ore was received during the week from the Granby mines. At the Le Roi smelter at Northport there was received during the week 1493 tons of ore. The Le Roi mine sent in 1435 tons and the First Thought 56. The district shipments for the week were: Boundary, 21,063 tons; Rossland, 5350; Slocan-Kootenay, 1733. Total for the week, 28,145 tons.

Special Correspondence.

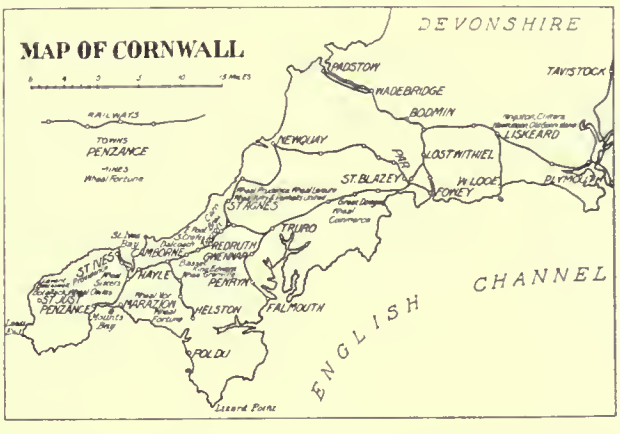
LONDON.

The Institution Meeting.—Salt Union and United Alkali Affairs.—New Plant for South Crofty.—Clitters Changes Management.

The annual general meeting of the Institution of Mining & Metallurgy was held last week and the revised rules of membership outlined in a recent issue of the MINING AND SCIENTIFIC PRESS were unanimously adopted, as were also the new rates charged for membership. I wish to point out that this increase in the yearly subscription for members from two to three guineas and for associates from one and a half to two guineas is not intended to affect present members or associates, or those who may be elected before the end of the present year. The new rates will be for new members solely. It will be to the advantage of those contemplating application for membership to hurry up and be elected before the end of the year, and so save themselves a guinea or a half-guinea a year ever after. At the general meeting the address of the new president, Mr. Alfred James, was read in his absence by Mr. Bedford McNeill. The address consisted of a sketch of the advance of things in general during the last twenty years. The most important point urged was the very great advance in the status of the English mining engineer in metallurgical work. When I was first connected with mining operations conducted from London fifteen or twenty years ago, there was a hazy idea that there were no English mining engineers or metallurgists at all. This notion originated in the London offices of American promoters and engineers, who were at that time in great vogue here. They granted that there were plenty of Englishmen who could do assaying and surveying work, but America had to be drawn on for men worthy of responsible positions. For ten years this idea reigned supreme, but it is now being gradually dissipated. Several reasons for this winning back of their birthright on the part of the Englishman may be given. One reason is that its originators are not now in our midst, and another is the increasing influence of the Institution of Mining & Metallurgy. I am fully convinced that the system of post-graduate scholarships inaugurated at the Royal School of Mines by the Institution will still further advance the status of the English mining engineer.

The Salt Union and the United Alkali Company are two national institutions that have been under a cloud for the last twelve years, owing chiefly to foreign competition. The Salt Union owns large tracts of the Cheshire salt fields. In 1888 when it was formed as a consolidation of a great number of minor interests, the output of salt was about two million tons a year and the gross profit £500,000. The nominal capital was £1,000,000 in preference and £2,000,000 in ordinary shares, while the debentures amounted to £1,200,000. At first a dividend at the rate of 10% was paid on the ordinary shares, but this soon fell away until it was only 1% in 1896, since when nothing has been paid until this year. The preference dividend has been paid intermittently from 1897 to 1906, the total for all these years being 18%. The yearly output of salt has for a long time been under the million mark, and has been as low as 800,000 tons. In 1902 a drastic remodelling of the business took place. The ordinary shares were reduced to £800,000 and the preference to £600,000, and many economies in administration effected. Some improvement in results took place, but it was not until 1907 that divisible profits were made. Even now the dividend on the ordinary share for 1907 is only 1¼% on the reduced value of the share, or ½% on the original value. The preference shares get 8½% on the reduced value of the share. The output of salt in 1907 was 910,000 tons and the net profit £127,075, the latter figure comparing with £70,104 in 1906 and £68,400 in 1905. The debentures take £54,000, and £52,000 goes to the preference shares, and £10,000 to the ordinary. It is to be hoped that this recovery will be maintained and the profits increased in future years. The other company referred to, the United Alkali, is a consolidation of a great many chemical manufacturers, copper and other metal producers, in Lancashire, Newcastle, and Glasgow. Formed when the chemical trade was booming, its capital on the reduced profits now ruling looks inflated, and the ordinary shares are not of great value. The nominal capital does not represent the actual present position of the company, and the poverty of the distribution on the ordinary shares is an anomaly that cannot be helped. The company is one of the best organizations existing, and the state of its ordinary dividend is its misfortune, not its fault. In 1907 a net profit of £479,349 was made. Of this £134,187 was distributed as debenture interest, £187,878 went to the 7% preference shares, and £56,875 to the ordinary shares, being at the rate of 2%. In addition £75,000 was placed to reserve and £15,000 to debenture redemption fund. The profits were slightly lower than in 1906, chiefly on account of the higher price of fuel.

The South Crofty is one of the Cornish mines recently taken over by a London group of financiers, Messrs. Allen & Meyerstein, who believe in a clean sweep of old Cornish machinery and a liberal expenditure of money on modern plant. It is nearly two years since they entered into possession. About £13,000 has been spent on new plant, of which £8000 has gone for a 40-stamp mill of the modern



type in place of the old Cornish stamps, together with Buss tables, Frue vanners, etc. The remainder has been spent for magnetic separators and electric machinery. About £31,000 has been spent in sinking new shafts, in exploration work, additional buildings, and general equipment. In December last the entire new mill was in operation, treating about 120 tons a day. Development has turned out so well that the directors have decided to erect an additional 40 stamps, and have issued 6000 new £1 shares at £4 each, to obtain the necessary funds. The policy of increasing output at the present juncture is open to criticism, as the results for the half-year ending December 31 last have not borne out the prophecies of the directors. But people are ready to put up the money. During the six months in question the amount of ore stamped increased from 50 to 120 tons per day. The total output of tin concentrates, wolfram, and arsenic is not given, but the receipts from the sale were £11,349, £3766, and £2002 respectively. The total expenses were £17,300, and after adjusting the accounts as to a number of small items, a profit of £195 was made. Last summer Mr. Allen was talking about a profit of £200 a day. Surely a good profit should be obtained before issuing new shares at such a high premium to increase the plant. The only excuse for increasing the new plant now is that the information already in the hands of the directors points to the fact that the margin of profit will be small unless the property is worked on a large scale.

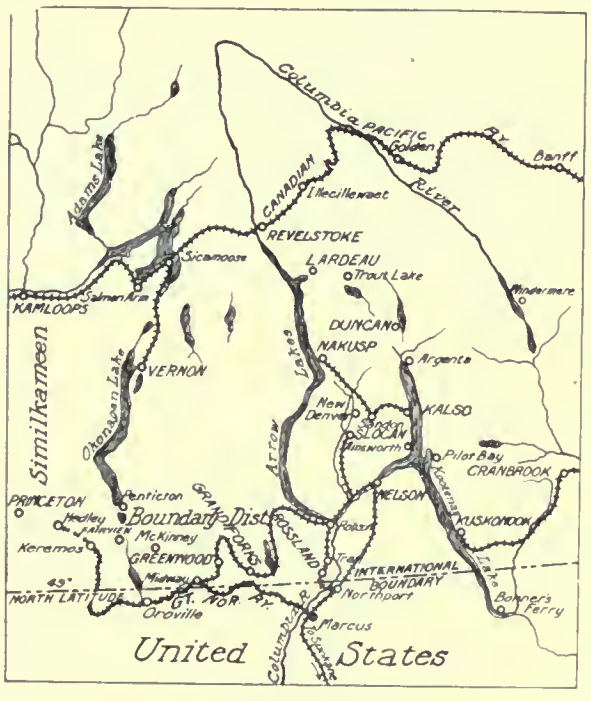
Last week I referred to another Cornish mine, the Clitters United, and mentioned that owing to a number of circumstances a loss had been made on working during 1907, in spite of the fact that an interim dividend had been paid during the year, and that further capital was to be raised. It is now announced that the Messrs. Schiff are resigning from the board and handing over control to the Allen and

Meyerstein group. It will be remembered that the Clitters was the first mine in Cornwall reopened by outsiders, and that in those days Allen and Meyerstein and Schiff worked in harmony. It was the Messrs. Schiff, and their consulting engineer, F. Dietzsch, who were the pioneers in reopening work and in designing the modern plant. The Allen-Meyerstein group are now supplying the new capital, and the management will in future be in the same hands as South Crofty and Botallack. The Messrs. Schiff are now concentrating their attention on the Wheal Jane mine near Chacewater. It would be interesting if more outsiders would take up Cornish mining, but most of the big firms are afraid. A well known American mining man said to me the other day that they gave Cornishmen credit for knowing enough about mining to have taken out everything that was worth taking already. The fact is that though the simpler tin ore at shallow levels is mostly gone there is both free concentrating ore at lower levels and complex ores in the upper levels that would pay to work with improved modern processes.

ROSSLAND, BRITISH COLUMBIA.

Railroad Building. — Several Important Branches. — Grand Trunk Pacific. — Mining News. — Ore Shipments. — Operations at the Granby. — Canadian Pacific Spiral Tunnel.

Work on a small scale has been started on the Pot, Alberta, and Sunset claims. It is reported that a new vein has been uncovered on the Sunset. The extensive development work being done on the Giant-California by the Granby Is showing good results. Ore shipments for the week ending April 11, amounted to 5350 tons; the



British Columbia.

Le Roi, Centre Star, and Le Roi No. 2 being the only shippers. The Trail smelter received 6150 tons for the week. This smelter and refinery is now producing 20,000 tons of lead annually, besides copper matte, fine silver, and gold bullion. The matte goes to the Tacoma refinery, the gold to the U. S. Assay Office at Seattle, and the silver to Ottawa, New York, and Hongkong. Richard Merton, of Frankfort, while in the Boundary last week stated that during his travels he had seen nothing that compared with the Granby workings for low costs and general economy. It was his opinion that copper would find its normal figure of 17c. or 18c. after the financial clouds had passed away. Granby shipments last week were lower than for some time previous. The product of the mines was 21,063 tons and the smelter treated 22,820 tons. The cost of mining and smelting has been got down to $2.50. On the 10th instant the Granby paid $55,000 to its employees in Phoenix and $35,000 at the smelter.

News has been received that the Minister of Finance looks favorably upon the application of the lead miners of the Slocan and that it is now assured that the extension will be granted and the limit raised from £16 to £18. A company has been organized to take over the Ophir-Lade, Lucky Jack, and Swede groups of the Great Northern Mining Co. and development work is to be resumed. The Silver Cup has opened up a good orebody. Their output of 160 tons in March netted $10,000. A strike of $80 ore has been made on the St. Elmo claim of the True Fissure group. Shipments through Kaslo for March were 548 tons. A strike has been made on the Half Moon at Moyie. The Sullivan smelter is to be operated until the ore on hand is treated.

Probably the most interesting piece of railway work being executed in British Columbia at the present time is that now going on near Field, on the main line of the Canadian Pacific. At this point the old grade is 4.5%, and it takes three and four locomotives to push the transcontinental trains up the hill. The Kicking Horse canyon being too narrow to permit of loops, the new railroad crosses the river and cuts into the solid mountain, and will be built through a tunnel 16 ft. wide by 24 ft. high, 3200 ft. in length, making a complete spiral and emerging at a point 70 ft. higher than the first entry. By means of tunnels the grade will be reduced to 2.2%. About 500 men are employed on the work and open-cuts; the grading should be completed by July or August. It will take 12 months to bore these tunnels.

The Fernie-Michel extension of the Great Northern is now about ready for operation. It is stated that passenger and freight service will be extended to Michel from Spokane as soon as a government inspector has examined and accepted the work. The extension of the V. V. & E. from Keremeos toward Hedley is now 20 miles from the first named town. There are yet some large cuts and fills to be finished and a couple of bridges in this 20 miles. Contracts have been let for clearing the right of way from Hedley to Princeton, a distance of 24 miles. There is no word of the resumption of construction on the Midway-Vernon.

It has been rumored here that the Canadian Pacific, which was understood to be behind the Kettle Valley lines, was to take over the property in April. However, this is denied by C. P. R. officials, probably because an act of this nature would annul the cash bonus that the charter of the Kettle Valley lines carried.

Ten million dollars will be expended on the contract just let for a portion of the western end of the Grand Trunk Pacific, and nearly 6000 men will be put to work as soon as the work can be got ready for them. The work to be started immediately is the 100-mile section from Prince Rupert to Kitsilas canyon, and 60 miles from Kitimaat to Kitsilas. Foley, Welch & Stewart, the contractors, are now engaged in collecting their outfit from points where they have been working in Manitoba, Alberta, Washington, and British Columbia. It will require 500 cars to transport their $200,000 equipment, which will include 600 horses, compressors, drills, graders, and scrapers.

BUTTE, MONTANA.

Hauser Lake Dam Bursts.—Wash-out Affects Great Falls Smelter.—Mines Resuming.—Helena District.

The Great Falls smelter of the Boston & Montana Co. has practically been shut down on account of the damage to the Great Northern railroad, between Butte and Great Falls, caused by the flood from Hauser dam on the Missouri river, which broke April 15. About 22 miles of railroad track was washed out. The Hauser Lake dam is the property of the Missouri River Power Co., which furnished electric power to nearly all the mines and smelters in Butte, and the accident cut off the power, necessitating a shutdown of all the mines for a day until connections could be made with the reserve steam power plants. The Boston & Montana Co. is shipping ore to the Washoe smelter at Anaconda.

The Washoe smelter has contracted to receive 100 tons of

ore per day from the Snowstorm mine, and shipments are expected to begin next week. The Washoe has about 6000 tons of Snowstorm ore in its bins now. It is used chiefly for converter linings. The Snowstorm will then be shipping nearly 400 tons of ore per day to various smelters.

The Butte & London Development Co. has finally been forced to succumb to the effect of the financial stringency, and has closed its property. The pumps have been taken out of the mine and the workings will be permitted to fill with water. The Butte & London started out as one of the best financed among the new companies, and continued work longer than many of them. It was the original intention to sink the shaft at least 1500 ft. before cross-cutting and doing exploratory work, but sinking progressed slowly, and the financial crash caught the company when the shaft was but 1100 ft. deep. It was then decided to explore the veins at that depth in the hope of finding commercial ore. Half a dozen good veins were cut and driving was done on two of them. They were opened to a considerable extent and bunches of ore assaying well in copper and silver were found, but it became evident that sufficient depth had not been attained. The treasury had become exhausted; several efforts to raise funds by the sale of treasury stock were unsuccessful, and a shut-down was inevitable. The company has been under the management of some of the most energetic operators in the Butte district, and their disappointment is keen in not being able to continue work. Mining men generally are of the opinion that the Butte & London will become a large copper producing mine some day. The company has no debts and owns its ground outright, consisting of more than 100 acres. It has the best surface plant and equipment of any of the new companies, and its large three-compartment shaft is one of the best in the district. The company has a large amount of stock remaining in the treasury, and if financial conditions improve it will probably have no trouble in raising more money.

Preparations are being made to resume work on the Pilot-Butte claim by the Pilot-Butte Copper Co., owned chiefly by Milwaukee capitalists. The latter also felt the financial squeeze, and a suspension of work was ordered about a month ago. The Pilot claim is located in the North Butte district, among big mines.

The Ida-Montana Co. is preparing to resume work on its properties in the eastern part of the Butte district, adjoining the mines of the Amazon-Butte Co., and will spend $40,000 on additional machinery for its plant and in putting in an electrical equipment, including a large electric pump that will be placed on the 1000-ft. level. The pump will have a capacity of 1500 gal. per min. The new machinery has been ordered and sinking will be resumed as soon as it is installed. The shaft at present is but 550 ft. deep, but will be sunk to the 1200-ft. level without stopping. On the 250-ft. level a vein 60 ft. wide has been opened, showing 7 ft. of good ore.

Sinking on the Raven shaft by the Raven Mining Co. was suspended some time ago and development work has since been confined to cross-cutting, but with no great success so far as the discovery of ore is concerned. A cross-cut has been driven to the vein on the 1100-ft. level, and work is going on there now.

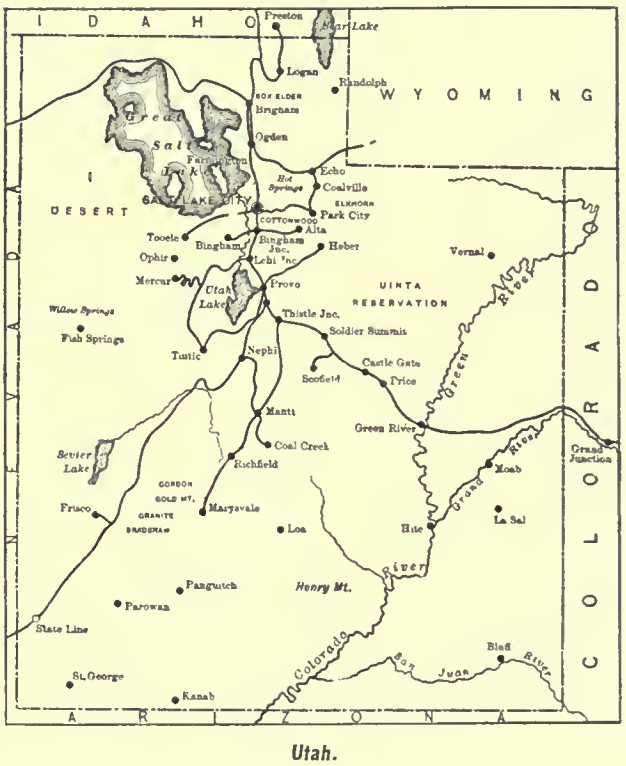
The Souvenir Gold Mining Co. of Butte, which is operating gold properties in the Helena district, is opening some rich free-gold milling ore in the Court House claim, which was the original Whitlatch Union mine, on the vein of which, in adjoining ground, a great amount of ore was taken out years ago. The vein is 10 ft. wide. Twenty inches of the ore on the hanging wall assays $72 per ton, and the remainder of the vein goes $20. The company owns 1500 ft. on the vein. A new lead has also been opened on the Wisconsin claim, owned by the Souvenir company, about 900 ft. south of the rich Spring Hill mine. The vein is 2 ft. wide and is free milling. In the Noyan vein a new orebody has been opened, the lowest assay of which gives $29 per ton. The company has a 10-stamp mill on the property and is installing new boilers and making connections with an electric-power line, with the object of operating the mill by electricity. The mill will be enlarged by the addition of 10 stamps, which will be in operation by the middle of May. It is stated that there is now enough ore on the dumps and blocked out in the mines to keep the mill running more than a year.

SALT LAKE, UTAH.

New Tintic Smelter.—Railroad Through Silver City.—May Day Resuming Work.—Apex Mine.—Novel Use for Churn Drill.

The Bullion-Beck and Champion Mining Co. are operating partly on company account and partly by leases, and are shipping 1000 tons of ore per month. The deepest workings are 1500 ft. below the surface, the shaft being 1300 ft. deep, with a 200-ft. winze below that depth. Mining is in progress on various levels from the 200 to the 1100 ft. inclusive. There is considerable water on the 1300, and a pump is to be installed on that level. The 1500 level, however, is not troubled with water, but permanent water-level was reached a short depth below it, that being on a level with the surface of Utah lake. The ore throughout carries silver chloride and lead carbonate, and a little copper in places. P. T. Farnsworth is general manager, with L. C. Doty superintendent.

The properties in the Tintic district controlled by Jesse



Utah.

Knight and asociates comprise the Beck Tunnel, Colorado, Crown Point, Iron Blossom, Black Jack, Star Con., and Swansea. The Colorado, Beck Tunnel, Black Jack, and Swansea are well developed and will supply all the classes of ore required at the new smelting plant which is being erected between Mammoth and Silver City. John Roundy is general superintendent of all the mines of this group, and under his direction they are being put in readiness for production so as to supply the new smelter with its required tonnage. A narrow-gauge railroad has been built from the smelter to the mines named, 7 miles in length, passing by way of Silver City. At the new smelter the sampling plant is finished, the two lead furnaces, 48 by 160 in., are installed, one blower is ready, and the flues, dust-chambers, and stack are finished. The stack is of steel, 10 ft. diam. by 150 ft. high. Hand roasters, of the reverberatory type, are being built and a sintering plant, designed by F. G. Kelly of Salt Lake, is being put in. Electric power will be employed throughout. Jacket-water, and water for fire protection, will be pumped from the 1000-ft. shaft of the Swansea mine at Silver City. For this purpose

a triplex electric-driven pump will be installed at the 1000-ft. station of the Swansea. The two lead furnaces are intended to be blown in about June 1. In addition to the above equipment, a copper furnace has been ordered. The plant was designed by H. P. Saunders, and will be operated under the superintendence of R. S. McCaffrey.

The May Day Mining Co. is operating the May Day and the original Uncle Sam mines under one management, utilizing the Uncle Sam shaft, through which all hoisting will be done. Prior to the shut-down last autumn they worked a force of 200 men, and a part of this force may be put on again by April 20. The Uncle Sam will soon be used for concentrating the second-class ore on the dump at the May Day mine. The Apex Mines Co., in which E. B. Jones, Frank P. Swindler, and others are interested, is prospecting and exploring its group near the Grand Central and Centennial-Eureka. A first-class hoisting plant and air-compressor were installed a few months ago. Since that time a shaft has been sunk 1325 ft. deep, and development is in progress from the 1300-ft. station. A winze is also being sunk. The shaft is three compartment, two being for hoisting purposes, and one for a manway. The cage compartments are each 4 by 4½ ft., and the manway 40 by 54 inches.

The United States Supreme Court has affirmed the judgment of the Court of Appeals in the Kempton lode mining

The New Tintic Smelter.

case, which has been in litigation for a number of years, which gives the United States Smelting, Refining & Mining Co. title to the Kempton claim, which is valued at $1,000,000. E. A. Wall is the loser by the decision. The Tintic Smelting Co. will begin to receive custom ores on May 15, and in preparation for this the mines of the Tintic district, which have been closed since about the first of the year, are preparing to resume operation. The lead furnaces will be placed in commission in June, and the copper department in the latter part of July or early in August. A transaction has been closed here for the purchase of the Carbonate mine, one of the oldest producers in Beaver county, by a New York syndicate. The Beaver Carbonate Mining Co., with headquarters in Boston, has been organized to operate it. The property yielded its former owners about $1,000,000.

At a special meeting of shareholders held in Salt Lake, the Nevada Douglas Copper Co. authorized a bond issue of $600,000, bearing interest at 6% and maturing in five years, but redeemable in stock at any time within three years at $7.50 per share. The proceeds are to be applied toward cleaning up the present indebtedness of the company, and further equipping its mines at Yerington, Nevada.

The foundations for the cyanide department of the mill of the Jennie Gold Mining Co. at Gold Springs, Iron county, have been completed. The plant will be in commission in about six weeks. Twenty feet of good milling ore has been developed in two parallel veins on the 115-ft. level. Assay value runs from $6 to $10 per ton.——Development work will shortly be resumed at the Silver King Con. mine at Park City. The Silver King Coalition Mines Co. has assembled a churn-drilling outfit at Park City, and will try the experiment of applying them to provide better ventilation. The first hole to be drilled will be one between the Alliance and the Hanauer adits. Ore shipments from Park City last week amounted to 649 tons, Daly Judge furnishing 279 and Daly West 37.

Practically all the equipment for the converter plant ordered for the Yampa smelter in Bingham canyon has been assembled and is being placed in position. It will be ready for use about June 1.

COBALT, ONTARIO.

Mining by Government.—Right of Way Mine.—Nipissing Property.—Ore Shipments.

The Cobalt mines began shipping silver ore in 1904, since which time approximately 25,000 tons have been mined and shipped to various smelters. This ore has averaged $760 a ton. Taking into consideration the narrowness of the veins we must conclude that the ore is very rich. While no smelters have been provided at Cobalt, there have been erected two concentrator plants for custom ores, besides which at least six mills have been put up on individual properties. We may now expect that the walls of the veins which often carry leaf silver, as well as the cullings from the ore already shipped, will provide quite a tonnage of profitable ore. The most noticeable feature of the district is the great number of small veins discovered and worked. It appears as if every inch of the ground must be prospected. Ore is being shipped to such widely separated places as Denver, Perth Amboy, N. J., Trail, B. C., Carnegie, Pa., Swansea, Wales, Hamburg, and to Thoroid, Ontario, the latter being a new plant. A smelter lately erected at Trout Mills will also handle Cobalt ores.

For some time past the Government has been operating a mine in the Gillies Limit for whose benefit it is difficult to determine. It appears rather singular that this mine should have been operated for so long a time without the conditions of the workings having been made public. We understand the shaft is down over 700 ft. As few of the Cobalt mines are down a third this distance it would be very interesting to have a geological section of this shaft. A recent paper reports that the first shipment of ore from this mine will soon be made and then continues, "in a short time now it may be expected that the Government mine will be placed on a paying basis. The ore is not of the richest quality found in the Cobalt area, but it is of good paying value, and the officials in charge of the mine are confident of the success of the undertaking. The work on the Gillies Limit has been carried out on the most modern lines, and much of that which has been of an experimental nature has resulted in the placing of important information in the hands of the department."

It would be interesting if those having the information would provide the figures for comparing the wet with the dry concentrating plants. The Muggley Concentrator plant has installed stamps with Wilfley and Frue machines for concentrating. The Lawson mine is still tied up with litigation. The case will go before the Court of Appeals at the next sitting. The Right of Way mine is certainly the most remarkable in the district. It will be remembered that the Government sold this strip of ground along the right of way of the railroad 99 ft. wide, and two miles long, for $50,000. The company had only been in possession a few weeks before they shipped a carload of ore which paid for the mine and expenses of mining. To date four veins of good ore have been opened, and all parallel to the line of the railroad, so that the narrow width has not lessened the value of the finds. The Silver Queen vein crosses this property into the Princess ground as well as some veins from the Townsite. The question has often been asked why the Nipissing, which has such a large acreage, does not lease portions of the property not now being developed. Such a course would be a benefit to the district as well as to the company. In fact there is less leasing of ground in Cobalt than in any other mining camp. It may be that the owners have such confidence in the value of the ground that they want it all for themselves.

MEXICO.

El Tajo Reduction Plant. — Ayutla Smelter, Jalisco. — Milling Output, Guanajuato.—Orteaga Mine.

A reduction plant with a daily capacity of 30 tons will be erected at the El Tajo property of the El Tajo Mining Co. of New York in the San Sebastian district. Orders for the machinery will be placed at once, and it is hoped to have it on the ground before the heavy rains commence. The plant will consist of stamps, concentrating tables, and a cyanide annex. There is plenty of wood available for fuel. It is estimated that the milling ore now available in the old workings of the Tajo mine is sufficient to keep the 30-ton plant busy for several years. By the time the adits now being driven are completed and new orebodies opened up the company will have its reduction process perfected, and will be ready to increase the capacity of its plant to 100 or 200 tons daily. The air-drill plant ordered for the Tajo mine some time ago recently reached the property and is now being installed. In a little while the drills will be in operation and the tunnel work will be moving along much more rapidly. Several substantial buildings have been erected at the mine. If the reduction machinery reaches the property before the rains block traffic, it is believed that it will be possible to have the plant in operation by next August or September.

The Ayutla smelter of the Carrizo Copper Co. is rapidly nearing completion, and plans are now being made to blow in not later than June 1. The furnace, blowers, boilers, engine, and other machinery are in place, and there now remains to be completed only the smokestack and dust-chambers. The fuel on hand consists of over 300 tons of coke and a big supply of firewood. Little, if any, charcoal will be used. The company has finished the erection of office buildings and bodegas, and the houses for the workmen are nearing completion. The concentrating plant at the properties of the Ayutla Mining Co. is in operation, and as soon as additional crushing machinery is received and installed the plant will be kept running night and day. The mines and mill of the Ayutla company are under bond to the Carrizo Copper Co. and ores as well as concentrates will be supplied to the Ayutla smelter. It is believed that these mines are capable of furnishing supplies for a much larger smelter than the present 75-ton plant of the Carrizo company. Ores from other mines in the Ayutla district are being purchased, and by the time the company is ready to blow in the smelter there will be a big supply on hand. The erection of the Ayutla smelter is attracting much attention, and as soon as smelting operations are commenced there is certain to be great mining activity in that section of Jalisco. At the present time there are few empty houses in the town of Ayutla, and rents there are advancing.

The present activity in Guanajuato is exemplified by the following output for March of the several properties doing a milling business there:

	Tons.
The Peregrina Mining & Milling Co.	12,400
Guanajuato Reduction & Mines Co.	12,600
Amalgamated Mining Co.	9,000
San Prospero Mill	6,000
Nayal Mill	1,500
Consolidated Mining Co.	11,200
Pinguico Mines Co.	6,750

In addition, the camp produced during the month 12,000 tons of high-grade shipping ore. The ores milled in this camp at present yield about ₱20 per ton. They consist in the main of the lowest-grade ores, and are mostly made up from dump and mine-fillings. All of the properties are, however, gradually increasing the grade of ore as mine development proceeds, and while the profits at present are very handsome from milling only the low grade of ore, the immediate future will show even more gratifying results.

The Orteaga Mining Co. of Cananea resumed operations on February 15, and is blocking out ore so that when the Greene-Cananea smelter starts up in June it will become a steady shipper. The ore struck three weeks ago in the 822-ft. tunnel is different in character from that prevailing in the district, containing much bournonite. The finer crystals assay copper, 41%, silver, 12 oz., and gold, 0.06 ounce.

DENVER, COLORADO.

Leasing in Clear Creek District.—New Oil Company.—Explosion in Coal Mine.—Cripple Creek Items.—Craig Placer Ground.—Bagley Tunnel.

The leasing system is steadily gaining in the Clear Creek district. At a recent meeting of the directors of the Old Town Mining Co. at Idaho Springs it was decided to operate the whole of this extensively developed mine under the leasing system. The old Pyrenees mine, near Central City, has been taken under bond and lease by F. M. Slater, who has had the property surveyed, and is now putting the mine in working order. The repairs on the Golden smelter are nearly complete. The plant will treat the ores from the Saratoga mine. The various tunnels, starting in the vicinity of Idaho Springs, were advanced with a fair degree of rapidity during March. Work on these enterprises is being pushed harder this month. The crew on the McClelland tunnel seems to be trying to equal or exceed the record being made in the Cripple Creek drainage tunnel. Articles of incorporation of the Colorado Springs Oil & Gas Co. have been filed in the El Paso county clerk's office. The company is capitalized at $1,000,000, divided into the same number of shares. The company intends to start drilling operations at once, about three miles southeast of Colorado Springs.

An explosion occurred at the Champion coal mine of the Royal Coal & Coke Co., of Durango, on April 14. The workings were badly wrecked, and three persons were fatally injured. A letter had been received by the superintendent on the previous Thursday, stating that the mine would be blown up unless made safe at once by repairs. The mine was at once inspected and declared safe. Investigation is being made by the county authorities.

The lessees mining on the El Paso Consolidated Co.'s territory at Cripple Creek, are now producing considerable ore. Their success has stimulated others. A new company has been formed, known as the General Leasing Co., which has taken a lease on the Hardwood claim on Ironclad hill. Abram Rapp, former general manager of the Gold Sovereign, is in charge of operations. Conundrum mine has been leased for two years to a company of Cripple Creek miners. One of the most important dump leases secured of late has been the one on the tailing dump of the old Rosebud mill, in Anaconda gulch. Craig, Norris, and Wright, the lessees, are shipping the tailing from this old chlorination mill to Colorado City. The Portland Gold Mining Co. has just distributed its usual quarterly dividend of 4c. per share, making a total of $7,867,080 paid by the company to date. A new company, known as the Craig Placer Mining Co., has purchased 680 acres of placer ground in the Craig district, and has secured water rights on Fortification creek by the purchase of the Meisner ranch.

The Frisco Mines Co. at Animas Forks reports fine progress on the Bagley tunnel, which is being bored into Houghton Mtn. at the rate of about 200 ft. per month. Only one shift has been working during the winter. The breast of the tunnel is now in about 4900 ft. and many veins have been cut during the progress of the work, among them the big Sewell vein, which is more than 100 ft. wide and which outcrops on the surface for a distance of two miles, all in the territory of the Frisco property. The continuation of the work will send the big tunnel through the ground of the Old Red Cloud and other famous properties of the early days, and when the north portal is reached, somewhere in the vicinity of Mineral Point, the Frisco people will have completed one of the really big feats in mining in the San Juan. The entire length of the tunnel will be about two miles. Little or no work has been done in exploring the veins which have been crossed, this being reserved for the future. With the arrival of summer and the regular running of trains to Animas Forks, it is probable that the task of driving the tunnel will be facilitated by adding one or two more shifts.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Rhyolite is an eruptive rock having the same chemical composition as granite. It may be considered the volcanic equivalent of granite, which in fact it would have become if it had cooled slowly enough to permit the fused mass to separate completely into distinct mineral grains.

Silica refers to a substance considered as a chemical compound, namely, the oxide of silicon, or silicic acid. The same substance considered as a crystallized body is known as quartz, whether occurring in definite crystal form or massive. In uncrystallized masses, of horn-like appearance, it is called chert or flint.

Tellurium may be detected by pulverizing the suspected substance, moistening sufficiently to cause it to adhere and not be blown away, and then strongly heated on a piece of porcelain in the oxidizing flame of the blow-pipe. A coating will be formed on the porcelain, which upon being moistened with sulphuric acid becomes rich crimson in color.

Meerschaum has been found in two deposits in the upper Gila valley in central Arizona, one being about 23 miles east of north, and the other at a mine about 12 miles northwest of Silver City. The deposit lies in the bottom and walls of Bear creek, occurring in veins and lenses. The quality is not equal to imported meerschaum, but it may improve when the unaltered mineral is developed.

A good method of thawing dynamite is as follows: Prepare a strong wooden box of the size required and line it with cloth. Have a tight fitting lid and place in the centre of the box a can, which is also covered tightly. Then place hot water in the can and cover that. Place the powder in the box and heat from the can of hot water will thaw the dynamite gradually and thoroughly, and then it can be kept for hours in a convenient place ready for use. The tight cover will retain the heat in the box for a long time, and all danger will be removed.

The color of slag in crucible assays often indicates the nature of the metal present. Light to dark green or black slags are colored by various proportions of ferrous silicate. When iron is absent, the color of lead silicates may predominate, or white and gray or colorless slags, due to silicates of lime, magnesia, or zinc, be produced. Copper produces red slag, due to cuprous silicate. Cobalt gives blue slag. Lead and soda form easily fusible silicates, and the latter should be used in excess with zinky ores, to prevent a pasty slag, which holds beads of lead.

Bauxite is mined in Arkansas, Georgia, and Alabama from irregular masses near the surface, generally enclosed in walls of boulders and clay. It is derived from the decomposition of highly aluminous igneous rocks. The best grade of ore ranges from 56 to 58% Al_2O_3 and about 8% SiO_2. The second grade averages 50% Al_2O_3. The ore should be free from iron. The ore is worth about $4.50 and the domestic output is about 78,000 tons, and the imports, chiefly from France, amount to 18,000 tons.

Platinum occurs in placers, and is not found in workable quantity in veins, although associated with copper and nickel in deposits of sulphide masses in Ontario, Canada, in Norway, and some other regions. It is also commonly associated with chromite, and is found in rocks rich in minerals carrying iron and magnesia. The grains found in placers are therefore supposed to have been derived chiefly from such rocks as peridotite and dunite. It does not occur in acid, that is, silicious rocks, like those of the granite-rhyolite group. An exception to this exists, however, in the case of a platiniferous quartz vein in New Zealand. This lies close to altered magnesian rocks, from which the platinum was undoubtedly carried in solution, to be subsequently deposited with the quartz. The natural solvents of platinum in the rocks are not certainly known.

Barytes is used for the manufacture of paints, porcelain, and as an adulterant and filler in paper and other industries. The principal producers are in Tennessee, Virginia, and North Carolina. The average price is $4 per short ton for crude ore. The raw material is first ground and then bleached with sulphuric acid, after which the product is worth about $18 per ton. The two most objectionable impurities are iron and calcite. Limonite is often associated with barytes, and this must be removed for paint manufacture, while calcite absorbs much acid, and hence is detrimental. The separation of barytes from the impurities has been effected by acids, but jigging is cheaper and the difference of specific gravity of baryte and calcite or gypsum, which are commonly associated, make this form of separation cheap and efficient. This method of separation will probably find wider application in the near future.

Phosphate rock occurs over wide areas in Utah, Wyoming, and Idaho, associated mostly with light-colored limestones near the base of the upper division of the Carboniferous strata. The underlying sandstones and quartzites from 200 to 400 ft. below the phosphate deposits, serve to aid its discovery, which is usually difficult owing to concealment of the beds almost everywhere by soil or slide-material. The deposits are almost entirely oölitic in structure, the grains being well rounded and black in color. The material possesses a bituminous odor. The lower part of the bed is hard and blocky, the middle portions contain large lime nodules, and the upper part is shaly. The demand for phosphate rock will increase as a means for profitably using the excess of sulphuric acid which will in future be yielded by the smelters as a result of suppression of the smoke nuisance. At present phosphate rock to stand shipment to the Pacific Coast must carry about 32% of phosphoric acid.

THE NEW SAN FRANCISCO.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

It is two years since the earthquake and fire. A year ago we marked the anniversary by publishing a number of articles descriptive of the re-building of the City. This year we shall comment briefly, for most of us are more intent on looking forward than glancing backward. The sentiment of the disaster has been worn threadbare.

While, in April 1906, San Francisco lost about 325,000 out of the 500,000 of the City's population, the return has been so nearly complete that the population is estimated today at 485,000. In the meanwhile the cities around the Bay—that is, Oakland, Alameda, Berkeley, Sausalito, etc.—have gained 135,000 inhabitants, so that the community by the Golden Gate has actually increased by 120,000. Immigration of home-seekers was evident before the earthquake-fire, hence it is manifest that the disaster did not deter those who wanted to live hereabouts. The fire destroyed buildings and contents valued at $350,000,000. About $180,000,000 has been paid in insurance. In the past two years building permits have been granted representing structures valued at $117,514,495, distributed among 14,370 buildings. Of these, 69 were of the best or Class A type, and they are valued at $16,452,000. In constructing these 14,370 buildings, there has been spent $47,007,797 in labor. There are now 200 hotels in the burned district alone. The financial storm, of October last, found San Francisco in a sensitive condition by reason of local need for money in reconstruction, but the banks stood the strain and the commerce of the City suffered only a temporary depression.

During the first year after the disaster anyone standing on the high ground west of Van Ness avenue looked back upon a ghastly desolation: today he sees the ruins almost obliterated by apartment houses and flats. Standing on California hill, near the Fairmont hotel, the observer then looked down upon acres of burnt brick and twisted iron, above which rose a few leviathan office buildings of steel construction, the grim survivors of a general holocaust. Though gutted by the fire, they were structurally intact, so it was not long before the hurried work of repair made them again the hives of industry. The Crocker, the Call, the Kohl, the Merchants Exchange, and the Flood buildings were among the first to be rehabilitated. It was nearly two years before the Chronicle and Mills buildings became retenanted. The Emporium building is not yet reconstructed. And while this work was being pushed forward with splendid energy, other buildings, some of them large and beautiful, arose out of the débris left by the fire. Among these the Alaska Commercial, the Pacific, the Humboldt Savings Bank, and the California Bank buildings are notable. Nearly all the important structures that were either partly or wholly destroyed two years ago, have been restored on their former sites. The position of the Examiner building is marked by a mess of iron and stone, an appropriate emblem for the incivism of its owner. The rubbish that marks the former site of this newspaper office is called a Class Hearst building and it is said that it can be "Leased as a hole or in part."

Yet to the visitor from other cities, the most striking change in our City is the mending and improvement of Market street, the highway leading from the water-gate of the Ferry building to the radiating roadways. This important engineering work was slow in visible result because the sewers, broken by the earthquake, had to be re-laid, and after that the level of the street was raised, having slowly settled, even before the earthquake, upon the filled ground that extends from Montgomery street to the Bay. The transverse avenue, called East street, which passes in front of the wharves, has also been re-laid and improved by a re-arrangement of the car-tracks, so that the incoming traveler will be impressed by the greater cleanliness and definiteness of this part of San Francisco.

The heart of the old San Francisco, at the meeting of Kearny and Montgomery streets, with the great cross-town artery of Market street, is now adorned by several splendid new buildings. On the southeast corner of Market and Second is the Balboa building; on the corresponding corner a block farther west is the Bank of the Metropolis; at the intersection of Post and Montgomery is the First National Bank. These are fast approaching completion and already add greatly to the appearance of the City. The site of the old brick structure of the Palace Hotel is now surmounted by an 8-story steel framework that, in a year more, will mark the restoration of a caravenserai famous the world over. The St. Francis, on Union Square, has been rehabilitated and a third wing added, so as to improve the proportions and add largely to the capacity of this hotel. The Fairmont was nearing completion in April 1906; it was not injured structurally and now proudly crowns the crest of California hill, occupying a site unequalled for panoramic view. Looking westward from the lower end of Market St., there is now to be seen the prow of the big Phelan building, a triangular structure standing on the gore made by the meeting of Market and O'Farrell streets with Grant avenue. It is a huge structure of 11 stories of steel, covered with cream colored tile, and presenting an appearance likely to remind the traveler of the Flatiron in New York. We give herewith a photograph of this building, as typical of the new San Francisco and as suggesting, by the name of its public-spirited owner, the fight for civic decency that more than many buildings of steel or stone has marked the renewed life of San Francisco. The earthquake shook other things besides the ground under the City, the fire consumed a corruption that was not all physical, the glare of the holocaust threw light on many dark doings. The moral upbuilding of San Francisco may not be as apparent to the traveler from east or west as the architectural rejuvenation, but surely it is the more important. In November last the corrupted and corrupting municipal government was driven out of office by the vote of outraged citizenship, and while much of the slime of a dirty kind of politics is still apparent in many a by-way, there is a better spirit abroad. The "warder of two continents" has set a watch on herself.

The Phelan Building and Market Street. The Flood Building in the Distance. Temporary Structures in Right Foreground.

The Fairmont Hotel.

THE NEW SAN FRANCISCO.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Yukon Gold.

The Editor:

Sir—Under separate cover, I am sending you copies of the complete reports and statements relative to the Yukon Gold Company. Enclosed herewith, you will find a tabulated statement showing how the total figures are reached.

Mr. Beatty's statement is merely an expression of opinion of the reports submitted to him, based on his personal knowledge of the country. Mr. Beatty made two trips to the Yukon when this business was in the making, and has had the full data before him covering the examination work, construction, and operation.

As to the supplementary report, I can only say that I have found Mr. Treadgold to be a keen and careful observer, and in all the cases where his statements have been checked by our own examination work, they have been confirmed. I personally consider that he knows more about the Yukon properties than any one man. He made a number of investments early in the Klondike excitement and has studied the gravels there for nearly ten years.

As to our own reports of valuation, would say that every property that has been accepted by the company and taken into its holdings, has been examined by our own engineers independently of any reports made us.

As to net results: The proposition has been criticized freely on the ground of impracticability, great pressure being put upon the mechanical difficulties, impossibility of handling frozen ground, etc. I feel that I am entitled to speak with some authority on these points: First, in regard to hydraulicking: With the limited water supply from the small gulches, hydraulicking has been carried on in the Klondike for a number of years, and successfully, wherever dump-room and water-supply were properly provided for. Our own hydraulicking operations on a small scale have shown a profit through two years' operations. We have provided for dump-room by purchase and control of the creek claims. A continuous water-supply during the summer seasons has been a thing unknown in the Klondike district. We have secured our water-supply from the main right fork of the 12-Mile river which, at the lowest stage, insures us a continuous supply of 5000 miner's inches throughout the season. All of the conditions for economical hydraulicking are present. The duty in the small operations previously conducted has been high, and on account of the extent of the deposit and the long faces which it is possible to open, I consider that we shall be able to use our entire water-supply to its maximum efficiency. We have provided, in the laying out of the system, for the application of the water at a number of points both in the creek-bottom and on the hills, insuring by the number of openings the highest possible duty. Taking our present hydraulicking cost as a base with the reductions that can be safely figured to result from a continuous water-supply, I feel sure that the 10c. cost for hydraulicking is a very safe average figure throughout the life of the operation.

Our dredging operations have also been severely criticized by a certain writer for the technical journals. We have realized from the outset the limitations of dredging in the Klondike, and have only installed dredges on the wide open valleys where the bedrock is suitable and on portions of the creeks where the gravel was thawed, or partly so. The dredgeability of the Klondike gravels has been thoroughly demonstrated by the operations of the Canadian-Klondike Co., which is operating a 7-ft. Marion dredge at the mouth of Bear creek, and by our own operations on Lower Bonanza. The Canadian-Klondike dredge averaged 2935 yards per day during the season of 1906, operating from May 9 to October 22. This fully equals, if not surpasses, the duty of a dredge of the same type in the Oroville field. Our own 5-ft. dredges have attained an average of 2000 yd. per day when operating continuously in thawed ground. We have never assumed that a dredge would handle frozen ground. As to the problem of handling frozen gravel: We have conducted a series of experiments extending over two years, embracing stripping the ground by ground-sluicing, thawing by steam points, and using water under pressure. We have never doubted the necessity of having water and plenty of it to prepare the ground for dredging where frozen. The object of our experiments was to determine the extent to which the gravel would thaw after ground-sluicing only, and

TABULATED STATEMENT CONCERNING THE YUKON GOLD GRAVELS.

	Perry.				Treadgold.		
	Yards.	Gross value.	Net value. 32c. for creek. 10c. for hill. Cost per yard.	Net value. 25c. for creek. 10c. for hill. Cost per yard.	Yards.	Gross.	Net.
Total creek gravels	36,450,000	$25,400,000	$11,500,000	$15,000,000	52,000,000	$34,050,000	$24,950,000
Total hill gravels	47,000,000	14,850,000	9,500,000	9,500,000	65,500,000	19,000,000	15,000,000
	83,450,000	$40,250,000	$21,000,000	$24,500,000	117,000,000	$53,050,000	$39,950,000
Probabilities in hill ground partly proven	16,000,000	4,100,000	2,500,000	2,500,000	20,000,000	5,000,000	4,000,000
Additional creek yardage assuming a reduction in working cost to 25c	10,000,000	3,500,000		1,500,000			
Equipment returned in cost as above			4,500,000	4,500,000			
Oroville and Atlin gravels			2,500,000	2,500,000			2,500,000
Allowance for probable extension and reduction in cost				2,000,000			
Grand total	109,450,000	$47,850,000	$30,500,000	$37,500,000	137,000,000	$58,050,000	$46,450,000

to what extent pressure water was necessary. A block of ground on '90-below' on Bonanza, which was completely frozen at the time of my first visit to the country in 1905, was stripped with the aid of a small nozzle under 30-ft. head in 1906 and was dredged in 1907 without the use of an ounce of fuel, the dredge working into the bedrock four to five feet to recover the values, and making an average for the run of 1780 yd. per day, which could have been increased to 2200 by taking less of the bedrock. This block containing approximately 38,400 yd., yielded 50.8c. per yd., at a cost of 24.1c., including depreciation. I cite this as an instance of what may be expected when the ground is properly prepared for dredging. Our thawing by steam points in advance of the dredges actually cost 14c. per cu. yd. and will be reduced to 12c. with our present equipment. The need for tailing-room made it necessary to start the dredges before pressure-water was available, and steam-thawing is our only resource at present. It is expensive, but not prohibitive. With water under pressures ranging from 550 to 900 ft. along the creek-bottom, I am thoroughly convinced that we can put all the ground we expect to handle by this method in condition to dredge for a cost not to exceed 5c. per yard. We will not only strip the moss and muck from the claims but cross-cut them with the giants to expose the frozen gravel, and open the way for the surface water to reach the bedrock. Some thawing with points will probably always be necessary, but it will be reduced to a minimum.

The mechanical elevators are as yet in an experimental stage. Similar machines have been built and operated not only in the Klondike, on Gold Run, but in the Cariboo district, and elsewhere. The machines have been designed with a view to making them strong, light, and portable, all steel construction, and capable of doing the work for which they are designed at a minimum cost. The cost is a pure estimate at present, but we do not expect to exceed 35c. per yd. at the outside, and the gravel to be handled by the elevators is rich enough to leave a large margin of profit at this cost figure. Our dredging cost we expect to reduce to the neighborhood of 20c. after water is available. To attain the above costs, cheap power is a necessity. We have provided for this by installing our own power plant of 2000-hp. capacity on the Little 12-Mile, from which we deliver power to our operations at a cost of not to exceed $3 per horse-power per month, which is much cheaper than the average California power cost.

The dredges in 1907, operating for less than 50% of their possible running time, absorbed over $65,000 in experimental stripping, and thawing charges, as well as the entire cost of operating a large power plant, and still showed a profit. The properties in the Yukon Gold consolidation have earned a net profit of over $300,000 while in the equipment stage where the operation has been confined to very small limits. This does not appear to indicate that the properties have no value.

New York, April 13. O. B. Perry.

[This matter is discussed in our editorial columns. Editor.]

Rawhide, Nevada.

The Editor:

Sir—I read with considerable interest an article in your paper of March 28, entitled 'Notes on Rawhide, Nevada,' by someone who evidently does not desire to sign his name, presenting a very discouraging, and, in my opinion, unfair view of a camp which gives promise of adding its quota in the near future to the already large production of a State which has risen in a few years from a position of comparatively insignificant precious-metal production to the second in the Union, Alaska included, according to the preliminary report of the Director of the Mint issued the first of January, 1908. This amounted to $19,831,214, and would have been much larger except for serious labor troubles.

The same kind of talk and doubt as this article expressed was constantly heard at Tonopah and Goldfield in the early days of those camps until development had demonstrated beyond the peradventure of a doubt the existence of large and highly profitable orebodies, calling the attention of mining men again to the possibilities existing in the porphyry formations where contacts of distinctive rocks like slate and diorite do not exist and where true fissure veins are not found. The vein formations being of the gash or fracture order, the adjacent country rock has been enriched by ascending mineral solutions dissolving out and replacing the country rock along the lines of fracture. Whether these fractures are caused by intruding dikes of a similar rock to the original formation or simply a slipping of one part upon another cannot positively be determined until sufficient depth has been reached to get unaltered rock sections. However, sufficient openings have occurred to form veins of no mean width that extend in quite regular directions for considerable distances. This is conspicuously noticeable on Balloon hill and farther west in the Royal Tiger district. On Hooligan hill and other areas there is an extensive stock-work system, which consists of small seams lying close together and occasionally a larger fracture up to two or three feet in width, all so highly mineralized as to make the surrounding country rock rich enough for profitable milling.

Opportunity cannot be afforded the many who go to a camp such as Rawhide to go through every mine and sample it or even a considerable number, as there are a hundred people going and coming every day to the more important properties, but anyone can see ore panned from the dumps showing a good amount of gold over a wide area of country. I was permitted to go down most of the properties I desired and take such samples as I chose; the results were usually good. For the information of any who would like to know I give the results of Mr. L. M. King's sampling of the Kearns leases, on Balloon hill, and the Miller lease, on Hooligan hill. This work was done for the primary purpose of determining the treatment best suited to reduce the ores on the ground. Mr. King's results were as follows: On the Kearns No. 2 he found a vein, 2½ ft. of which on the hanging wall side gave returns of $5000 in gold and 150 oz. silver. Under this there is 8½ ft. of ore which shows

$54 in gold and 2½ oz. silver per ton. This would make an average of $1300 per ton for a width of 11 ft. This exposure was at 65 ft. in depth, and I do not know where it has been equalled for so small an amount of work done. The last shipment, of about 50 tons, from which returns have been had from this property, which contained but a small portion of this high-grade ore gave results of $198 per ton. The sample of the dump on the Miller lease gave the average of $45 gold and 10 oz. silver; the width of this vein is over 20 ft. The sample that was obtained from the Kearns No. 1 assayed $250 gold and 129 oz. silver, but was not a general sample of the mine but of some of the richer parts, as the vein formation is very wide on this property. As a result of these findings a contract has been let for a 50-ton mill, as a first unit of a 200-ton plant, to be ready to be run in 90 days.

To say that "there is no quantity of high-grade ore opened up in the camp at present" is quite misleading. It may not be 'blocked out,' but it is 'discovered.' It is only, in my judgment, a question of time and some more work to block out sufficient ore to satisfy the most exacting. It takes time to develop any camp, as well as money and faith. Rawhide is too new to have accomplished this yet, but they are going after it pretty strong. Thus, 14 hoists are either installed or being installed and 9 or 10 others are in transit—a remarkable showing in so short a time. The town is at present built ahead of the mines, but this is always the case and Rawhide is no exception to the rule. Considering that this place has come forward at a time when money conditions are tight the world over it has made remarkable progress and is a credit to the energy and pluck of the men who are honestly trying to make another Nevada camp to add more money from out the ground to the channels of trade. They are deserving of all the help they get.

San Francisco, April 12. E. S. Shanklin.

The New Association.

The Editor:

Sir—One of the reasons given for the proposed society of mining engineers is the hope that membership in it will mean something, this I believe will be the dominant issue. The members will be mostly live and successful men, so it is improbable they can meet without technical discussions. Could J. P. Channing and W. R. Ingalls spend an evening together without talking metallurgy, and could they let S. F. Emmons and W. Lindgren off without wanting their latest geological impressions? Would the editor of this paper say "Hush gentlemen, those are forbidden subjects, let us talk about professional ethics, etc., as proposed in my editorial of March 28."

I suppose all the instigators of the association belong to the A. I. M. E., and it is proposed by one or more of them to make future membership also entail membership in the Institute, establishing an affiliation. This would mean a cost of $20 per annum, instead of $10, with corresponding benefits. Then its members could possibly present and discuss papers at their own meetings and give to the Institute for publication, inscribed as read before and edited by the more select society; and the latter could aid in the cost of publication of these papers, thus perhaps sending them out more attractively illustrated.

I want to put in a plea from the rank and file of the Institute for the continued benefit of the teachings of the men who will compose the new order, and if it can be arranged, to get them for the present $10 per year. The Institute does not directly convey any dignity, either to the men who would form the new society, or to those left behind, but I have always thought it a sign of the best endeavor that the young engineers, foremen, millmen, and men simply engaged in mining as a business, joined the Institute. All of them read more or less of the Transactions they can understand, and if there is any paper on a district in which they are interested, there is sure to be a well thumbed copy at hand. These men did not enroll for prestige, but are paying a usually hard earned annual due to learn from the wisdom of their elders.

No honor which the new society may confer on the successful men who will comprise it is begrudged, and I think that most of its members will be broad enough to wish to continue to help the less wise who form the bulk of the Institute. After all, reputation and honor is founded on work known to the masses. Among the many holding the names of Clarence King and S. F. Emmons in respect, how few know of their enrollment among the members of the National Academy of Sciences, which should constitute the most exclusive association in America?

Denver, April 6. J. B. Hastings.

Antimony Ore in California.

The Editor:

Sir—Referring to the price of antimony ore in California in your issue of February 29, I beg to state that the difference between the unit price for ore and that of pure metal shows a margin of $1.80, or 2 tons of 50% ore would cost $60, and the metal contained in same would sell at $240, leaving $180 for treatment, loss, and profit. In England 'Star' is quoted at £35 and 50% ore at £10, leaving £15, or $75, for the smelter. Notwithstanding the expensive cost of treatment, and loss during reduction, a plant should pay well if erected at a suitable spot where regular supplies of ore are available. The losses of antimony, in a well equipped works, should not exceed 10%, and $40 to $50 per ton of refined metal should cover smelting charges. With metal selling at $240 per ton, the formula on which ores were formerly bought in France would work out as follows:

40 to 60% ores.

Price of 'Star'	$240
Deducted by smelter	100
	$140

or $1.40 per unit.

The price per unit paid for ores carrying 10 to 25% antimony is half that for the rich ore, or 70 cents. The difference between the American and English prices, being about $60 per ton, should prove a wide enough margin to pay all expenses.

J. Henry Rickard.

Newquay, Cornwall, March 23.

GOLDFIELD, NEVADA.—I.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

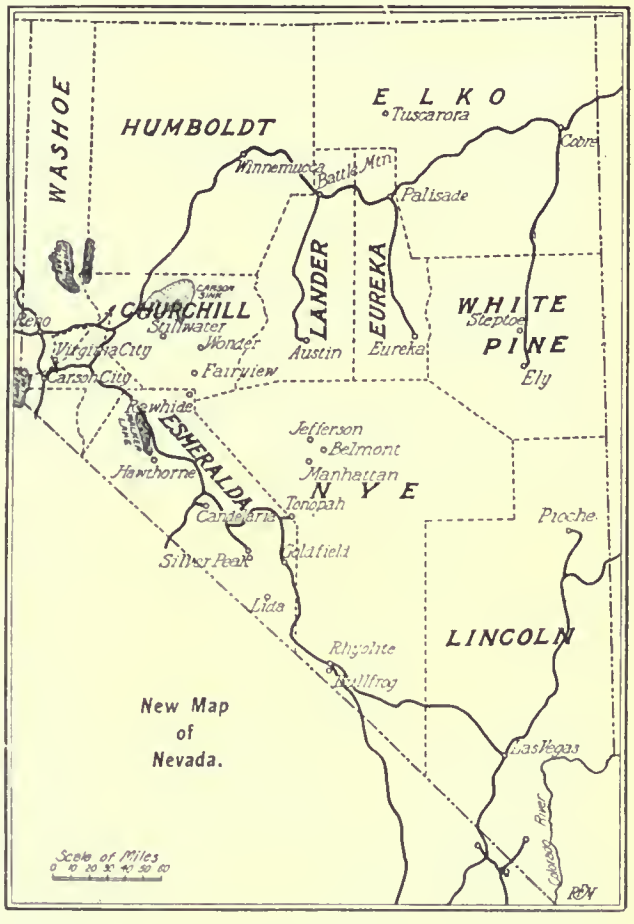
Goldfield has been twice christened. In its very infancy the camp was called Grandpa; this savored of frivolity, so the name was changed to Goldfield. It must have been a spirit of prophetic presumption that led the first discoverers to arrogate for the locality the name of The Goldfield, as if it were the one and only great gold-producing district of the world. But Fate and some fostering star have justified the baptism of the pioneers. Goldfield *is* today *the* goldfield of America.

When Harry Stimler and his partner called the place Grandpa they did not claim that it was the parent of the Mother Lode of California; it was a play on such names as Tonopah, Ivanpah, and Ibapah. These are of Indian origin; *pah* means water. Tonopah is a corruption of Tonumba-pah, which stands for 'water brush.' Iba-pah is red water and Ivan-pah is white water. Thus the Ivanpah range and the Witwatersrand are synonyms, for both mean the 'white water range,' and they sound as unlike as their sponsors, the Indian of the Nevada desert and the Dutchman of the African veldt.

Tonopah not only suggested the first name of the district, it was the parent of Goldfield. When I was in that part of Nevada in the spring to 1899, to make an examination of a copper deposit in the range east of Luning, all this part of Nevada was dead, from an industrial standpoint. Only the decadent glories of the Comstock reminded the traveler that he was in a mineral region once so famous. At Candelaria there was a little mining, and the stage road to Bodie from Hawthorne, up the canyon that led across the State line into California, recalled the excitement of a former era. The country had been abandoned by the prospector. It was one of the has-beens of history. The old trails still left faint lines across the sagebrush desert and over the bare rocky ridges and spoke of a period of strenuous search for gold and silver. Some of those abandoned paths of exploration went close to the places where rich mines have been discovered. The road from the north went close to the present site of Manhattan; in fact, there was an old camp within four miles of the one that sprang into existence in January, 1906. The old road to Montezuma, along which prospectors had traveled for fully 35 years, traversed the big flat east of Lone Mtn., and was within a few miles of both Tonopah and Goldfield. There was a trail that passed within a stone's throw of the Mizpah outcrop, which beckoned the miner for many a long day before Jim Butler thought of testing the black rock.

Like navigators that pass a treasure island in a fog and hear the muffled roar of the breakers only as a warning of danger, so these old prospectors went past the hungry-looking outcrops of silicified rock, never dreaming that they capped the wealth they were seeking with such invincible restlessness.

The first discovery in this region was made at Southern Klondike, a place half-way between Tonopah and Goldfield, which are 24 miles apart in a straight line. This first discovery was made by James Courts in 1898. The name suggests contemporaneity with the great rush to the Yukon. The outcrop of the Tonopah lode was plainly visible to those who went near it; in fact, Courts says that he and his partner used to go over the trail through the Mizpah pass and they employed the cropping of the Mizpah (or Tonopah) vein to shelter their campfire from the wind. At that time Jim Butler was at Belmont. In 1900 he made a trip from Belmont to Southern Klondike, and on his return he tried to make a short cut and so happened to tramp over the site of Tonopah. He saw the outcrop and picked up some pieces of the broken vein, taking them to Southern Klondike, where there was an assay-office run by on old man named Frank Hicks. This assayer threw the samples away, saying that he would not give a



dollar for 1000 tons of such stuff. Butler jokingly offered him a quarter interest for an assay. The ore was full of the black sulphide of silver (argentite) and anyone familiar with silver ores would have known that it was tremendously rich. These gold prospectors were ignorant concerning the other precious metal, so they blundered like tenderfeet.

On his way out Butler got some more of the black mineral and took it to Belmont, where he gave it to T. L. Oddie, who happened to be there in connection with the operation of a quicksilver mine. Oddie was an educated man and was then the District Attorney of Nye county; he lived at Austin, where he had been for several years as representative of the Stokes interests. Oddie sent the specimens to Walter C. Gayhart, an assayer at Austin. Butler promised Oddie a quarter interest, and Oddie promised Gayhart a half of his quarter—all for the making of an assay! Money was scarce; they were all of them 'busted.'

Gayhart's assays showed that the selected specimens ran from $300 to $400 per ton. Oddie thereupon sent an Indian runner to Butler's ranch, which was 45 miles from Belmont, to tell him of the strike; but Butler remained inactive. He was reputed to be "the laziest white man in the world." Even his location monuments are indicative, for they are built of seven or eight stones at the most. He never did a stroke more than necessary, if as much. Meanwhile Gayhart spoke publicly of the discovery and several men left Southern Klondike with the idea of finding it; but they failed. Three months after the assay had been made, Butler went to Belmont; he arranged with Oddie and Wilse Brougher (the recorder for Nye county) to make a trip to the scene of discovery. They gathered the necessary supplies at a cost of $25, which was about all they could scrape together. This was in August, 1900. On arrival at the spot, they located seven claims and then started to work. A small shipment was taken away in their spring wagon. This lot of ore was selected stuff and weighed slightly more than a ton; it was hauled all the way to Eureka, 170 miles distant. The partners received $600 as the result of that first shipment. Thereupon, in October, they started to lease the ground they had located, dividing their claims into blocks of 100 ft. square, to be mined on a royalty of 25 per cent.

When Hicks, the assayer at Southern Klondike, heard of the find, he picked up the specimens he had thrown away and assayed them. Then he claimed a quarter interest, and the matter was finally adjusted by Butler donating him a $^1/_{32}$ interest. He had no legal, nor even moral, right to share in the discovery. Butler's action was generous—generous as the spirit of the West, and of the pioneer the world over.

On June 3, 1901, only seven months after work had begun, the property was bonded by O. A. Turner for $337,000, of which $50,000 was paid at once and distributed, according to their holdings, to the five owners, namely, Oddie, Butler, Brougher, Gayhart, and Hicks. Turner drew at sight on his friend and associate John W. Woodside, of Philadelphia, a snuff manufacturer. In this deal Turner was assisted by J. H. Anderson, who became the first president of the Tonopah Mining Company of Nevada, which was organized with a capital of $1,300,000, of which $1,000,000 was in common shares of $1 each and $300,000 was preferred stock carrying 8%, the latter being subject to recall at any time. One share of preferred entitled the subscriber to two shares of common stock. The common stock rose eventually to $22.50, so that several fortunes were made and lost before it fell to its present price of $8. The mine never needed any working capital, it was a profitable enterprise from the very start. Before the leases expired on the last day of 1901 they yielded $3,000,000 worth of ore. Up to the end of 1903 the mine yielded $5,576,000, of ore averaging $160 per ton. In the following January the late William C. Whitney, the New York traction promoter, bought Woodside's 280,000 shares for $7, and a few months earlier John Anderson sold his smaller holding to a group of Philadelphia men headed by John W. Brock and W. L. Elkins, who was a director at the time of his death. Brock retained his shares and became president, retiring a few months ago. In order to diminish operating expenses, a railroad 60 miles long was built by the Tonopah Mining Co., so as to connect the mine with the Carson & Colorado railroad, a narrow gauge line running south from Reno. Construction was begun in January and the road was completed in May, 1904. In 1905 the railroad gauge was widened to the standard, so as to correspond with a similar change on the branch of the Southern Pacific, with which it connected at Sodaville. This railroad enterprise proved highly profitable for a time and was managed so as to be more remunerative than the mine itself. It aided the development of Goldfield, to which we now return.

By his share in the Tonopah mine, Jim Butler thus became rich and the patron of other prospectors. At the end of 1902 he 'grubstaked' or outfitted Harry Stimler (a half-breed) and William Marsh, two young fellows of Tonopah about 20 years of age. They went south and found rich float on what is now Columbia mountain, which overlooks the site of Goldfield. After searching in vain for the source of the rich float, they prospected northward and found gold in the surface dirt. Thereupon, the Sandstorm was located on December 2; the name of the claim suggesting the state of the weather at the time. The Kendall was located immediately afterward. In both cases free gold was found in the débris of disintegrated rhyolite and this led to a brief excitement, but no large orebodies were uncovered and the interest of the neighboring prospectors soon waned. In the spring following a party of Tonopah men sent a couple of prospectors to the new camp, then called Grandpa, as already stated. The prospectors were A. D. Myers and Tom Murphy. They located the Combination on May 24, 1903. Here let me relate a typical tale of hard luck. R. L. Johns, a lawyer then residing at Tonopah, happened to go into a store and was told by the proprietor that a pool or syndicate was being made for the purpose of sending a couple of prospectors to Grandpa. Would he take a share? It would cost $50 at once, with $50 more to be paid later. Johns said he guessed he would, and later in the day he returned with the money, only to be told that he was too late, another man having subscribed for the share. Johns did not bother about it, until he ascertained that the other fellow had subscribed his $50 with the $50 Johns had himself lent the other fellow the day before. So the reader can imagine the feelings of Mr. Johns when the prospectors found a good lode, which became the basis for a big mine, and one-twelfth of it had been secured by the $50 lent to another man who had jumped in and subscribed for the share our legal friend had expected to take.

At the time the Combination claims were located, no ore had been found. Tom Murphy, who was one of the discoverers, says that he located the Combination because it was the vacant territory nearest the Sandstorm; all the ground south from the latter had been located. Moreover, there was a large outcrop of quartz rock on the Combination, but that did not

mean much, for there were many similar combs of silicified material rising above the desert all around Columbia mountain. Myers, who was Murphy's partner, made a cut near the top of the hillock because there the detritus was thin; he found a stringer carrying gold in the midst of a mass of barren quartz. This stringer panned nicely and assayed as high as $83 per ton. Then he went down the side of the ridge and drove a short tunnel, which cut the lode at 20 ft. below the surface. He found good ore. This led to the big orebody now marked by the cavernous pit named the 'glory hole.' In the following October the Combination No. 1 and 2 claims and eight other locations were bonded by L. L. Patrick, acting for Arthur Winslow and J. D. Hubbard, who were trustees for two exploration companies. The ground was bonded for $75,000, of which $5000 was cash. This $5000 was the only money ever required, for the remaining payments were paid, as they became due, out of royalties on ore mined by successful lessees. On March 1, 1907, the Combination mine was sold to the Goldfield Consolidated Mines Co. for $4,000,000. In the previous 25 months the Combination had yielded $786,000 in profits to the owners, besides enriching many lessees. So ended a most profitable mining adventure; and it is pleasant to relate that among the beneficiaries was a scientific geologist and mining engineer, for Arthur Winslow was State Ge-

ologist of Missouri before he applied his technical training to the exploitation of a bonanza.

The early discoveries made in the Goldfield district gave no indication of the marvelous wealth it was destined to produce. The first find, on the Sandstorm, was bunchy and close to the surface of the rhyolite, which occurs in thin flows. This yielded fully $500,000. On the Kendall claim, which is partly in the same rhyolite and partly in tuffs associated with them, the surface dirt was rich, forming a concentration due to wind action; it was an eolian placer. When deeper mining began a vein was found several feet wide and profitable down to 30 or 40 ft. More recently renewed exploration has resulted in the discovery of a good width of ore at 70 ft., the gold being remarkably free. Another patch of gold-bearing débris was found on the Velvet, half a mile east of Columbia mountain; also in the rhyolite on the Cimarron claim. All of these patches of rich stuff—the cream of the geological dairy—stimulated prospecting and led to tentative digging into the combs of iron-stained quartz and silicified rock that appear on the sagebrush plain south and east of Columbia mountain. In two cases only was any noteworthy ore uncovered. There was the stringer that Myers found on the Combination and there was the outcrop on that part of the Jumbo subsequently included in the Bowers & Kernick lease. On this spot a defined vein was found within the 'blow-out' or comb of silicified dacite. A stope now breaks through the surface, and most of the outcropping mass for about 20 ft. in width will assay $20 to $25. But there was nothing to indicate the presence of the wonderful orebodies of the Mohawk mine; in places there were combs of silicified dacite shading into quartz that bobbed to the surface from under the detritus, due to erosion and wind action, but this stuff did not show gold in the pan and was neglected by all the early prospectors. The great bonanza might have remained locked in the heart of the desert if the developments in the Combination mine, which is on adjoining ground, had not stimulated the sinking of shafts in search for 'impossibilities,' as a local geological authority of German extraction, calls them. But they found the golden ore, rich beyond the fondest dreams of avarice, wonderful beyond the expectation of geological vision, and in quantity enough to turn a dozen good fellows into ordinary millionaires, as will be related in the sequel.

Manufacturing as Compared With the Reduction of Ores.—In a manufacturing establishment the buying of supplies presents no special difficulty, while the sale of the product needs skill—sometimes of the highest—and even then at a sacrifice of profit. A mine reduction-plant may be considered to have no anxiety regarding its principal supply of ore, or, at least, if the supply is not forthcoming, it is helpless; on the other hand, its product is easily sold at the market quotation, at any rate, to the metals selling companies. A custom reduction-plant needs skillful buyers, who, with good money in their hands, make every endeavor to procure ore, and sometimes fail to get it in sufficient quantity or quality.

The Prospector.

Owing to the large number of specimens forwarded to this department, it has been found necessary in future to make a charge of 25 cents to subscribers for each determination, and $3 to non-subscribers.

M. F. B., of Boston, Mass., sends a specimen of serpentinized rock containing pyrite.

The metallic mineral in rock sent by R. L. H., of Wardner, Idaho, is galena. No tellurium is present.

Rocks from Wallace, Idaho, marked P. 10, are: No. 1, quartzite with specular hematite; No. 2, quartzite.

G. G. C., of Schurz, Nev., sends: No. 1, quartzite; No. 2, quartz porphyry; No. 3, limestone with gypsum veins; No. 4 and 5, quartz.

The specimens sent by E. I. F., of Baker City, Oregon, are gneiss, the larger piece containing much pyrrhotite and some veinlets of pyrite.

A specimen of porphyritic rock which may be classed as quartz-porphyry or rhyolite-porphyry was received from M. T. C., of Red Mountain, Colorado.

Minerals from Tacopa, Cal., sent by K. & L., are: No. 1, calcite; No. 2, resembles magnesite, but is a silicate of alumina, magnesia, soda, and some lime. Probably a variety of amphibole.

Gold and Silver in Thermal Springs.—Interesting evidence on the origin of gold and silver in quartz veins is given by certain hot springs in the centre of existing hydrothermal activity in New Zealand, the Taupo volcanic zone. Sinter taken from the rim of a very ebullient spring at the Maori settlement of Whakarewarewa was found to contain, on analysis, silver to the amount of 4 oz. 18 gr. per ton, and gold to the amount of 1 dwt. 4 gr. per ton. The sinter analyzed was stained with sulphur, but showed no visible evidence of any sulphides. Analysis made from the sinter deposited in a wooden trough used to conduct water from the same spring at Whakarewarewa gave the following result in the precious metals: Gold, 12 gr.; silver, 15 dwt. 3 gr. per ton. The great geyser of Waimangu, which broke into action some years after the terrible Tarawera eruption of 1886, and remained active until November, 1904, deposited a blackish material, consisting chiefly of sulphides, but containing neither gold nor silver. Some mud obtained by Dr. Wohlmann, the Government balneologist, from a hot spring in the sanatorium grounds at Rotorua gave the following somewhat remarkable analysis: Silica, 69.30; alumina, 4.52; iron oxides, 2.00; titanium oxide, 0.58; lime, 1.00; magnesia, 0.10; soda and potash, 1.30; sulphur, combined, 1.40; sulphur, free, 6.09; organic matter, 10.01; water, 3.70%. Microscopic examination of the deposit showed that it consisted mainly of quartz and amorphous silica with a little feldspar. The mud also contained 5 gr. gold and 6 dwt. 1 gr. silver per ton. It is evidently not a deposit from the spring, but is merely a siliceous tufa impregnated by the thermal solutions.—J. Mackintosh Bell in *The New Zealand Mines Record.*

THE SEPARATION OF SLIME IN CYANIDE TREATMENT.

Written for the MINING AND SCIENTIFIC PRESS
By HORACE G. NICHOLS.

The process herein described first suggested itself in connection with the dewatering of tailing at a property in Central America. At this mine a partial draining of the tailing was resorted to in ponds, and the re-handling and transportation of the partly dried tailing to the cyanide plant was unsatisfactorily performed by an unreliable class of native labor. The cyanide plant was frequently closed by reason of inability to handle the tailing, and thus the great need of an efficient method of separating solids, however finely divided, from water, gave rise to experiments with a settling tank and conveyor belt. Two facts were soon noted: first, the great influence upon the rate of settlement of slime in water produced by removing the solids as they settled, and second, the applicability of the method in cyanide treatment. The first of these points was discussed in a paper recently read before the Institution of Mining & Metallurgy.

One of the principal causes which retards the settlement of slime or finely divided material is held to be, in greater measure than has heretofore been appreciated, the accumulation of the slime itself in process of settling. By avoiding such accumulation, free settlement of the solid particles is obtained. The principle involved is that of removing solid matter as fast as it reaches the bottom of the tank in which it is settling. The effect is that the solid matter settles very compactly if not allowed to accumulate, and its removal prevents the thickening of the liquid above. To quote from Julian and Smart, 'Cyaniding Gold and Silver Ores,' p. 219, "Retardation is a function of the depth measured from the top of the still turbid portion of the liquid to the bottom of the vessel," and "An increase of suspended matter causes a decrease in the rate of subsidence." If then the solid contents of a pulp-charge were removed as they settled, or in other words, if there were no bottom, in the sense implied, to the settling vessel, then this factor of retardation would be eliminated, the increase of density would be avoided, and the continued settlement of the slime would be unimpeded. The logic of this principle of free settlement, which implies this elimination of the retarding effect due to an increase of density in the medium during settlement in a closed vessel by the accumulation of the slime itself while settling, may perhaps not be perfectly clear, but the experiments carried out will, it is believed, establish the fact.

The retarding effect of the thickening of the medium on the falling of fine particles in water was shown by taking two equal portions of the same pulp and introducing them respectively into two cylindrical graduates, one of which was empty, and the other partly filled with water. The relative rates of settlement were as stated in Table 1. This shows in the case of graduate B, in Fig. 1, that even after the settled pulp had acquired the same consistence as that in the initial condition in graduate A, the rate of settling continued to be greater than was the case in graduate A, and it is suggested that this fact may have a bearing on the extremely compact nature of the slime deposited under these conditions.

A further step may be made by comparing the rate of settlement of a charge of pulp in a vessel closed in the first place at the bottom and in the second place connecting with a second closed vessel

TABLE 1.

filled with water and placed below it. In the apparatus shown in Fig. 2 the lower vessel and connecting tube were filled with water up to the stop-cock

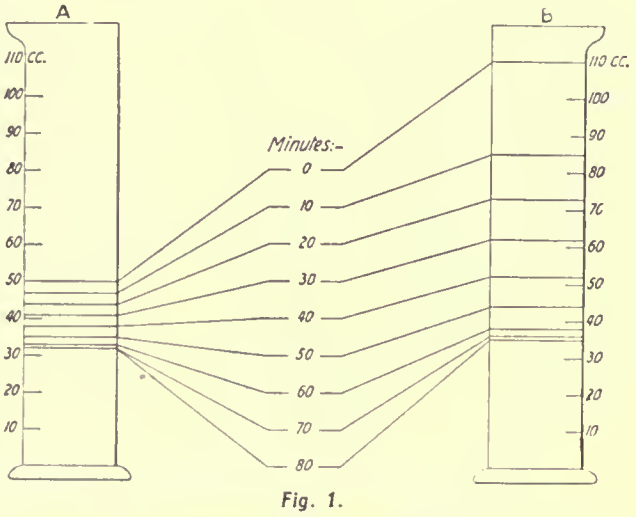

Fig. 1.

C, which in the first place was closed. A charge of 800 c.c. of pulp having a specific gravity of 1.544 was placed in the upper vessel and allowed to settle. In 90 minutes this charge had settled through a distance of 46 mm. leaving the supernatant liquid clear, the turbid portion measuring 154 mm. The upper vessel was then emptied and a second similar charge introduced, and the stop-cock C opened. In 45 minutes this second charge settled through 46 mm., the same distance as before. In 70 minutes it had settled through 114 mm., and in 90 minutes only clear liquid was left in the vessel.

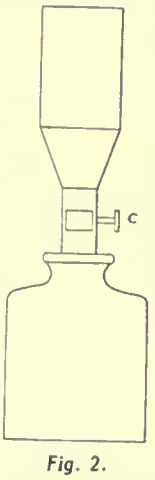

Fig. 2.

If in place of providing the lower vessel as a receptacle for the settling slime, such slime was removed as fast as it settled by a conveyor belt traveling under the upper vessel, the same result would be produced, in that the specific gravity of the medium is not allowed to increase toward the bottom, and

the settling is thus accelerated in the same measure. These results are held to accord with the noted acceleration in the settlement of slime in distilled and hot water, due, it is believed, to the reduced density of the medium, and they tend to show the marked effect on settlement produced by small variations in specific gravity.

Some interesting work recently carried out in South Africa has demonstrated the fact that a variation of a few degrees in the temperature of solution used in cyanide work produces a marked difference in the time required for settlement of slime. The difference in specific gravity due to this variation in temperature is of course quite small, and it may be objected that, in itself, it is out of proportion to, and cannot account for, the results. It is, however, contended that the experiments here described indicate a far closer connection between the variations in density of medium and the rate of settlement than has been understood to exist, and it is suggested that there is a wide field for investigation before it can be stated what is in proportion, or out of proportion, to achieved results. Much interesting and useful information has also been published in connection with the settlement of colloid slime, the electro-static condition of slime particles, the conditions of ionization, etc., and there is no doubt but that such conditions affect settlement. It is, however, suggested that the results of the experiments conducted during the past two years afford grounds for believing that a more important factor is to be found in the principle enlarged upon in this article.

The experiments were made in British Columbia on an ore of quartz, with argillaceous material, containing about 2% sulphides of iron, zinc, and lead, and particular care was taken to separate the heavier and coarser portions from the pulp to be used, by crushing in a stamp battery, with high discharge, and by passing the pulp through a hydraulic classifier. The overflow from this classifier was used in making up the charges, and contained 86% of material which passed 200-mesh (I. M. M. standard dry screening). An apparatus shown in Fig. 3 consisted of a pyramidal shaped tank about 4 by 5 ft., connecting at the bottom through an 8-in. square aperture with a closed box in which a 10-in. belt was made to travel slowly, power being supplied to the head roller D. The tank was provided with a trap door just above its connection with the box B, and this door could be removed from above as desired, thus allowing free passage between the two vessels.

In conducting the tests described, a charge of pulp representing a charge from an agitator was run into tank A, and trough B was filled with water to the same level. While all the pulp was still in suspension (air agitation being used) the trap was removed and the belt run in the direction indicated by the arrows at a speed averaging 4 ft. per min. The removal of the solid matter from the belt was effected by a scraper, in order that each individual 15-minute discharge might be weighed separately for percentage of moisture.

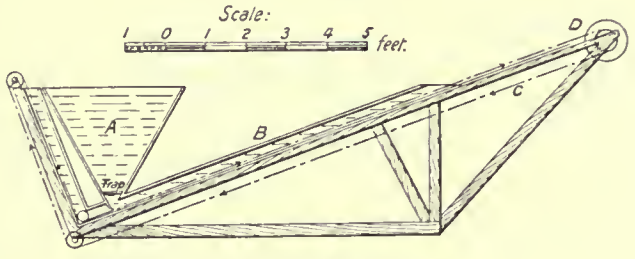

Fig. 3.

Table 2 represents some results from one series of tests out of a great number made with this and a previous appliance, in which the belt was much larger in proportion to the tank, and they show the character of the wet slime discharged by the belt in consecutive periods of 15 minutes. It was found that the finest slime was carried out of the tank and discharged by the belt.

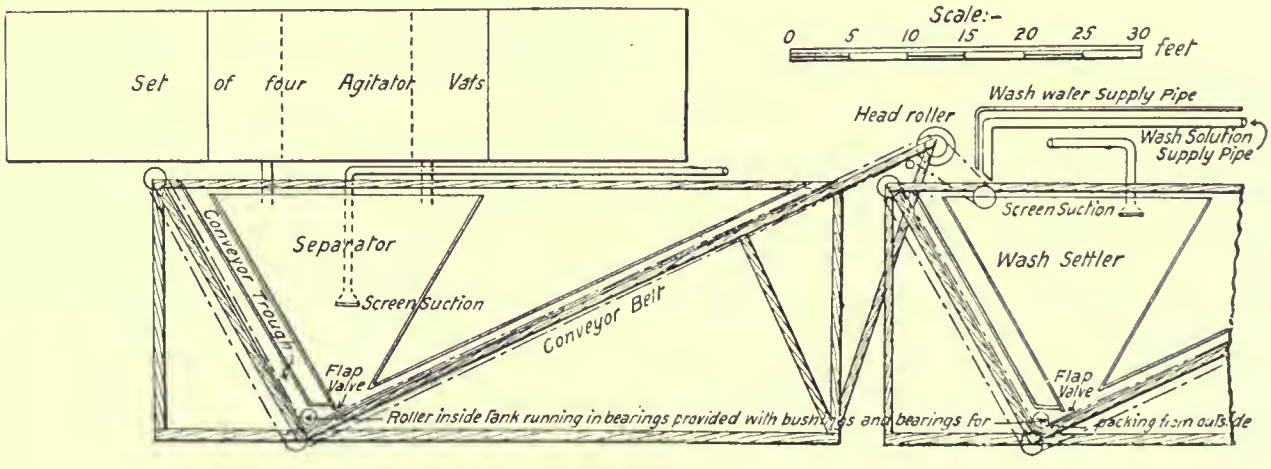

Fig. 4.

In preparing the tables of results it was found convenient to estimate the percentage of solid matter in the discharge by determining the specific gravity, having that of the ore known, and calculating from the formula,

$$P = 100 \frac{S(A-1)}{A(S-1)}$$

where A is the specific gravity of the pulp, P the percentage of dry slime in the pulp, and S the specific gravity of the dry slime. Checks were made on a number of individual charges by evaporation to establish the correctness of the calculations, and in view of its admittedly astonishing character the

whole of the discharge from charge No. 6 (898 lb.) was dried and weighed.

A series of successive charges was run, in which each succeeding charge was added to a residue from a previous one. It was found that the fine slime did not tend to accumulate in the tank and under the belt, and the latter was found to move with such little power that friction was evidently very light. In another series of charges the last traces of slime were removed by the belt in each instance, and it will be seen that the average discharge of a finely crushed ore in the case represented did not contain over 25% moisture, including the finest slime, which was recovered completely from the water, while from a pulp containing 40% solid matter the initial discharge carried but 22.5% moisture. Such a discharge is more comparable with that of filters than with the product of settling tanks.

The apparatus adapted to practical working conditions, with original separating vat followed by a wash vat from which the pulp is separated in the same manner is shown in Fig. 4.

The number of new devices for filtering slime which are now before the mining public is evidence of the difficulties attendant upon the simple method of settling and decantation still largely employed. The two greatest objections to the simple settling process are, the time consumed, and the large percentage of liquid left in the slime even after the most perfect settlement obtainable in the ordinary pointed tanks. The method of settling here described has given remarkable results both in the completeness of the separation effected and in the small proportion of liquid carried off by the solid matter. The process may be applied in one of two ways: first, it might be used as an intermittent process in which a charge of pulp from an agitator vat would be run direct to a separator (see Fig. 4) which would be of sufficient capacity to hold the whole of such agitator-charge in addition to a residual charge from a previous operation. The object of this would be to allow of extracting on the belt only such proportion of the solid content of a separator-charge as could be effected with the economic minimum of moisture. The belt-discharge from this separator would be delivered into a second similar tank, with the addition of weaker solution or wash water or both, and the liquid so added could be sprayed on to the discharging belt so as to loosen and disintegrate the discharged slime, or a mixer might be added for this purpose.

After withdrawal of the required portion of the solid content and clarification of the solution left in the tank, the latter would be withdrawn, either by decantation or by suction, to the original level, thus permitting the introduction of a second charge. A third wash settler may also be used. Secondly, this method may be applied as a continuous process by the simple introduction of a suction and filter.

It is found that the percentage of moisture carried over in the discharge varies inversely with the percentage of solids in the separator-charge, and the first portions of a discharge from any given separator-charge are always better than the succeeding portions, hence we arrive at the fact that if the density of a separator-charge be maintained at its initial density the percentage of moisture in the discharge would be kept at a minimum and the rate of discharge materially increased. Further, it has been found that if provision be made for keeping a filter or screen surface free from accumulated caked slime, which has been done by providing an automatic periodic cutting-off of the suction applied to such filter or screen, and applying a small back-pressure, that it is possible to continually withdraw clear solution from a pulp having a specific gravity as high as 1.4. If the belt and suction then be so correlated with regard to a given supply of pulp that while the one removes the solids the other takes out the proportionate amount of solution, it is evident that a continuous supply of pulp can be kept running to the separator, which would then always contain a charge of uniform specific gravity. Thus it is apparent that the initial discharge from charge No. 6, containing 22.5% moisture, would be representative of the uniform discharge obtainable from a supply of pulp of the specific gravity stated.

Were it not that the solid constituents of the pulp

are being extracted by the conveyor belt from the bottom of the vat, the continued use of screen suctions would, of course, not be possible, but by this method it is only necessary to adjust the relative capacities of the belt and suction in order to provide an absolutely continuous process of separation. Practically the same course of procedure obtains in the wash-settlers. The discharge is washed off the belt by precipitated solution and water, and the suctions arranged to withdraw an equal amount of solution. This solution is passed through the extractor boxes and returned from the sump. It may be noted that in other processes the completeness of washing is dependent upon time and the capacity of the plant, inasmuch as each instalment of slime is taken separately and washed solution passed through it as long as it is economically possible to do so, after which such instalment has to be removed, whether perfectly washed or not, to make room for the next succeeding instalment. In this method continual progression through the plant is unimpeded, and the slime may be washed with any reasonable amount of weak solution desired, without in any way affecting the time of treatment, the only factor affected being the capacity of the extractor-boxes.

Among the advantages of this method, it should be noted in the first place that the conveyor belts take the place of other means of transference, such as pumps or carrying machinery used in other plants for filtering slime, and that all other appliances and mechanical contrivances are done away with, as gravity alone performs the separation by reason of the possibility of taking advantage of the principle of free settlement. It will be seen furthermore that the separation of sand from slime is not called for, and consequently the many disadvantages attendant upon methods which depend upon close classification are obviated. It is also possible to wash to the best advantage, and thus reduce the loss in residual moisture by cutting down its value per ton as well as the amount.

Instances have been known in which fine grinding has been carried to an excess in order to make vacuum filtering possible. In this process of separation, where the degree of fineness or uniformity is wholly immaterial, the demands of extraction alone are the criterion of grinding. The initial cost is very low, and the adjustments are simple and easy to make. The best results have been obtained from charges containing high percentage of solid matter, and it may be claimed that the only limit to the thickness of a charge is the point at which it will not run. This feature is of great importance, as it is only required to run the charge from the agitator to the first separator, and therefore greater opportunities are afforded for preliminary decantation and thickening of the agitator charge. Finally, it possesses the great advantage of being a continuous process.

Petroleum at Virgin City, Utah, was encountered at a depth of 566 ft. It is a light grade of asphalt-base oil, testing 22° Beaumé. There is a relatively large quantity of sulphur in the form of hydrogen sulphide, which can be easily eliminated by steaming.

HEAT OF FUSION OF SILVER-LEAD BLAST-FURNACE SLAG.

Contributed to the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

The slag was of the composition SiO_2 33%, FeO 28.5%, and CaO 25.7%. The results were as follows:

	Number of experiment.	Pound-calories.
	1	314
	2	300
	3	310
From pot at furnace,	4	314
" " " "	5	296
" " " "	6	300
" " " separator,	7	335

The last result indicates that the slag when poured into the separating furnace absorbs heat. Comparing two furnaces, No. 3 and 4, there was found at No. 3 furnace: Experiment No. 1, 295 lb.-cal.; No. 2, 291; and No. 3, 300; while at No. 4 furnace, where the slag was not reducing as well, and where it stood longer before making the test: Experiment No. 4 showed 266, and No. 5, 280 lb.-cal. Seven other concurrent results give an average of 298 lb.-cal. We can say accordingly that under normal conditions the total heat of fusion may be taken at 300 pound-calories.

The experiment is thus performed: Into a felt-covered bucket is put a weighed quantity of water, say 15 lb. A ladle receives a portion of the molten slag as it runs from the furnace and two or three pounds is poured promptly into the water, granulating the slag. The water and slag together in the bucket are stirred with a stick, while the rise in temperature is noted by means of a delicate thermometer. The water before the experiment should be at a temperature below the surrounding air of one-half the actual rise of temperature of the water.

A new precipitation process for gold and silver from cyanide solution invented by P. de Wilde of Geneva, Switzerland, consists in acidulating the solution, thus setting free aurous cyanide (AuCy), and hydrocyanic acid. The AuCy is then caught and precipitated in intimate mixture with cuprous cyanide (Cu_2Cy_2), which is formed by stirring into the solution cuprous chloride (Cu_2Cl_2) dissolved in a strong solution of common salt. The Cu_2Cy_2 may be dissolved out of the mixture without decomposition by the use of dilute HCl. The resultant solution, containing HCl is used in the double function of neutralizing more fresh solution and of precipitating the AuCy. After precipitation of the gold cyanide, the acid solution contains free hydrocyanic acid, representing about 90% of the alkaline cyanide originally present. This is regenerated as sodium cyanide by adding a slight excess of caustic soda. The insoluble residue of gold cyanide (AuCy) left from the treatment of the precipitate with dilute hydrochloric acid is dried, roasted, and melted. A point of importance to be observed in the acidulation of the auriferous cyanide solution is that after adding a quantity of the stock HCl solution, with its dissolved Cu_2Cy_2, the Cu_2Cy_2 will remain in solution in the excess of alkaline cyanide. Sulphuric acid is then added, which precipitates the aurous and cuprous cyanides simultaneously.

TENDENCIES IN THE STUDY OF ORE DEPOSITS.

By Waldemar Lindgren.

*We know full well that this is an age of specialization and specialists. Fortunate indeed is he who is in full mastery of the principal features of all branches of his science and who can give his time to broad general questions, such as, in geology, the life history of this planet, the origin of its continents and mountain ranges. It is perhaps true that we have too few men who can devote themselves to such broad work and thereby obtain a wide and undistorted perspective. But the fact remains that most of us must specialize, must try to advance our science in our small way, the only way which we can adopt, to push our little special branch farther into the unknown.

In the study of ore deposits one of our chief aims is to trace the laws of migrations of metals, and of transformations of minerals. These theoretical aims are indissolubly connected with practical questions. The miners who utilize our work are very likely to put this question to us: "We read with much interest what you say in regard to the genesis of the deposit and its manner of formation, but, coming down to the point, what we wish to know is: Where are our orebodies; to what depth can we hope to follow them; how shall we find them if they are lost?" This strong utilitarian tendency follows us throughout our work, and undoubtedly the study of the ore deposits has suffered in some cases by being too closely connected with exclusively practical bureaus. Under such conditions the investigator of ore deposits, as Ransome has put it, is in danger of becoming a geological engineer.

The study of ore deposits was first inaugurated and put on a scientific basis in Germany, and that country has ever since maintained its proud position as one of the leaders in advanced thought. In the United States, aided by generous appropriations from Federal and State sources, and, on the other hand, by the existence within our borders of a series of mineral deposits remarkable no less for extent than for variety, the study of ore deposits has ever found a congenial place, and, it must be admitted that at the present time we stand at the head of the nations in extent of practical and theoretical investigations. We are also fortunate in possessing a body of mining engineers with sufficient geological training to appreciate and describe what they see. Germany undoubtedly comes next in general activity, though here the advance appears to be less due to State aid and to extensive work undertaken by government bureaus than to individual workers, generally those occupying chairs at the many German universities. The field in Scandinavia is not as broad as that of the United States, and is in fact largely confined to deposits of iron ores and to pyritic deposits, but nevertheless Sweden and Norway have always held a prominent place in the study of mineralogy and ore deposits. In Austria and Hungary also are some able men advancing the work. In France and Italy there are comparatively few workers, perhaps only two or three of note in each of these countries, but they make up in their earnest and successful work for the lack of numbers. Considering the world-wide interest of England in the mining of precious metals throughout the world it seems rather singular that so little attention is being given to ore deposits by the geologists and engineers of that country. It is true that there are notable exceptions to this, but with English mining engineers working in the most remote parts of the world it seems as if their contributions to the science of ore deposits is disproportionately small. On the other hand, the English colonies and dependencies have ever interested themselves deeply in the study of ore deposits. In Australasia and Canada a great deal has been accomplished, and many valuable reports are contained in the records of the State survey. In Latin America, Mexico has taken the lead formerly occupied by Chile. American and German investigators have produced notable results in Brazil and the Argentine Republic. Even Peru has awakened to the necessity of a geological study of its ore deposits, as shown by many recently issued bulletins.

It is not necessary for me to enlarge upon the great advance in the study of ore deposits which has been effected by the application of microscopic study of the rocks and ores. I think it is fair to say that great progress has been made during the last years in the universal appreciation of the necessity of such microscopic study and the unreliability of observations which are not supported by such testimony. Aside, however, from numerous studies of minerals peculiar to ore deposits no new methods of much importance have been developed, except in one case. I refer to the application of metallographic methods to the study of opaque minerals, which has recently been brought out by Mr. William Campbell, and which has already yielded such excellent results in the study of Canadian occurrences.

The geologist beginning his study of ore deposits is perhaps not at once deeply impressed with the necessity of chemical work. But this position is soon likely to change and he comes to recognize chemical work as absolutely essential. He then feels deeply his own insufficient knowledge of analytical chemistry and realizes that the experimental work to support his deductions must be done by a professional chemist. Unfortunately it is most difficult to find chemists who are also interested in geological studies and who have means or opportunity to pursue them.

As to the general method of study of ore deposits two ways are possible. We can either make a monographic study of a given deposit or group of deposits, considering them alone and tracing their origin and history by detailed observations. On the other hand, we can neglect in some degree the minor features of each deposit and instead study a great number of adjacent localities in their geographic and geologic relations. Two methods thus contrasted, the monographic and the geographic, have both been tried in the United States, but most weight

*Abstract of Presidential address delivered before the Geological Society of Washington, December 19, 1907.

has ever been laid on the monographic treatment. Undoubtedly the geographic treatment offers great possibilities, and it should be more emphasized in the future. At the present time in this country we are in the position of knowing a limited number of districts with great minuteness, but concerning the distribution of the metals and their connection with geological structure, the "metallogenetic provinces" of DeLaunay, our knowledge is insufficient. The most prominent advocate of this geographic treatment is at present Professor De Launay in Paris, and it is especially emphasized in two of his publications. The first is a study of the mineral wealth of Africa, published in 1903; the second, published at the last Geological Congress in Mexico, a similar monograph of the distribution of mineral deposits in Italy and adjacent parts of France, Switzerland, and Austria. In his own words DeLaunay "desires to show the distribution of the various regional types of mineral deposits, and the accord of these types with the geological structure, with the age of the rocks, and with the eruptive districts." Both books, and especially the latter, furnish much instructive reading, and the treatment could be followed with success in some of our publications. Mr. Spurr, in his Tonopah report, has also emphasized the necessity for geographic discussion of the distribution of deposits and speaks of "metallographic provinces."

There is another subject which is of great importance in our science. I refer to the study of the hot springs, which modern investigation has so clearly shown to be the carriers of metals and the cause of many ore deposits. We know what has been done in the past and how stimulating have been, for instance, the researches of Becker of the Steamboat Springs in Nevada and at the Sulphur Banks, of California, but the fact remains that very little has been accomplished in recent years to further advance this line of study. The study of hot springs, particularly in the Western States, should be undertaken not only from the monographic, but also from the geographic standpoint, and such treatment will be very likely to result in valuable generalizations. It is true that numerous analyses have been made of individual springs, and sometimes also of spring deposits, but to be of value such examinations must be carried on with special precautions and great detail. Many interesting facts have been developed. I refer, for instance, to the discovery of cinnabar and gold in spring deposits of New Zealand; to the discovery of tin in certain hot spring deposits in the Malay Peninsula; and to the studies of the Doughty Springs of Colorado by Headden, showing the deposition of barite and the presence of radio-active substances. Dr. Delkeskamp in recent numbers of the *Zeitschrift für praktische Geologie* has undertaken a study of mineral springs in Germany, but this work does not contain so much of new chemical research, but is rather based on old materials. An effort in this line has been made by Jaquot and Willm, who some ten years ago issued a monograph on the mineral springs of France, accompanied by most instructive maps and tables showing the relation of the waters to the geological structure. Unfortunately the work was not primarily undertaken from a geological standpoint. More recently DeLaunay issued a useful volume on hot springs, but the wide scope of the work in some degree impaired its value.

Attempts have been made, as you know, to perfect a genetic classification of ore deposits, but it must be confessed that we are still far from the goal, and many editors of text-books candidly throw consistent genetic classification to the winds and describe ore deposits geographically, or by metals, or by the old terms of bedded, massive, or tabular deposits. Two genetic terms have, however, found general acceptance after their recent introduction by Stelzner and Beck. The terms are *syngenetic* and *epigenetic*. The former comprise those deposits which originate simultaneously with the surrounding rocks either through the differentiation of magmas, through mechanical deposition, or through chemical precipitation in seas or lakes. In the epigenetic deposits, on the other hand, the ores formed by filling or metasomatic action are later than the encasing rocks. During the last years many deposits have, by prevailing opinion, shifted their position in relation to these two genetic distinctions. A comparison of the older text-books with those of today will show this convincingly.

In general the syngenetic class of igneous origin has grown considerably. As shown in recent papers by Löfstrand, Stutzer, and Sjögren the views as to the genesis of the enormous deposits of North Swedish apatitic iron ores have changed, and these ores are now with considerable confidence regarded as products of magmatic differentiation on a large scale, in part even as distinct eruptive dikes. It is only fair to say that among the older advocates of a sedimentary or igneo-sedimentary mode of origin, this view does not find acceptance. The syngenetic class has also gained by the interpretation of certain pyritic deposits, such as the Sudbury ores as products of differentiation of igneous rock magmas. Coleman and Barlow have, as you know, recently described these deposits, but here too we find their views challenged by a few geologists.

On the other hand, there exists today a very strong tendency to transfer many occurrences, formerly held to be of syngenetic-sedimentary origin to the epigenetic class. A few examples will bring this more vividly before us.

The copper and lead-bearing sandstones, shales, and conglomerates have long attracted attention, and the consensus of opinion was that the metals had been precipitated through chemical agencies from the sea-water. During the last few years, on the other hand, continued research has shown that they are much more probably epigenetic, that is, that the minerals in their present position have been concentrated in the beds after the sedimentation, and this view is held not only by those who believe that the metals came from below carried by ascending spring waters, but by observers who think it more probable that they represent concentrations effected by surface waters.

Still another example of a change in genetic classification is furnished by the pyritic deposits, for many

years favorite battle-ground for mining geologists. Some twenty years ago it was generally believed that these large masses of copper-bearing pyrite, generally encased in amphibolite or in clay slates, were of true sedimentary origin. We still find defenders of this theory, but their number is rapidly diminishing. Perhaps the most notable supporter of the syngenetic view is Professor Kloekmann in Germany. He holds, for instance, that the large orebodies of Rio Tinto in Spain have been caused by the accumulation of pyritic concretions in a plastic shale mud charged with the chemical constituents of the pyrite. The origin of the iron and sulphur is sought in submarine flows of volcanic rocks. In a somewhat similar way he would explain the Mansfield copper shales, the lead-bearing sandstones of Mechernich, and many other deposits.

Professor Bergeat of Clausthal maintains the same origin for pyritic masses. He is especially certain that the beds of Rammelsberg are formed by sedimentation, and, although not quite as pronounced in his opinion as Professor Klockmann, inclines to the belief that all of the pyritic deposits are of a similar nature.

On the other hand, the prevailing trend of modern thought is unquestionably away from these views. Beck advocates unhesitatingly an epigenetic origin through ascending solutions for the majority of these deposits. Gregory has lately in a careful description of the Mount Lyell mines in Tasmania strongly maintained an origin by ascending solutions. The recent literature in the *Zeitschrift für praktische Geologie* contains many articles on pyritic deposits, and in the majority of cases the epigenetic features are strongly insisted upon. You are no doubt aware that Professor Vogt, of Norway, holds similar and still more radical opinions, thinking, in fact, that most of the pyritic deposits are products of magmatic differentiation. Our knowledge of the contact metamorphic deposits is constantly widening. From being considered oddities or exceptions they have acquired their rightful and important position. The papers of Professor Kemp have largely contributed to this. In a recent paper Mr. Fukichi describes twenty-four such deposits from Japan.

Correct ideas on metamorphism will ever help us in achieving true explanation of ore deposits. The great work of Van Hise on metamorphism, published in 1904, and the work of Grubenmann, which appeared in 1904 and 1907, place for the first time the study of the metamorphic processes on a thoroughly scientific basis. Few ideas have been more fruitful than the conception of the several zones of the depths, each distinguished by its prevailing set of chemical reactions and by its own set of minerals. With proper limitations these conceptions can be applied most successfully to ore deposits, especially when we endeavor to ascertain the laws in accordance with which mineralogical character and depth of deposition are related. Wherever studies of the mineralogical and other essential characteristics of deposits can be made in connection with approximately accurate estimates of the thickness of cover eroded away since the ores were primarily deposited, such investigations will lead us far toward a true insight into mineral deposition. DeLaunay was perhaps the first to follow this line of reasoning in an important article published in 1900 on 'The Variation of Metalliferous Veins in Depth.'

Naturally, perhaps, we lay stress on the processes of first deposition, but it is well to remember that in the majority of cases our mines are working on ores resulting from the re-arrangement and often from the concentration of the originally deposited material. It is surely not necessary to recall the important advance in our knowledge of these processes made by the almost simultaneous announcement in 1900 by Emmons, DeLaunay, and Weed of the secondary sulphide concentration. In our literature on this subject there is perhaps some confusion of terms in the employment of the words 'primary' and 'secondary,' and it is always advisable to be precise in the use of these expressions. De Launay employs the term "*remise en mouvement*" for the general secondary changes in ore deposits, which perhaps could be best rendered in English by migration. This migration may be effected by new supplies of ascending waters, but more generally descending surface waters are the agents. Much attention is given to these migrations in recent literature; Krusch in the *Zeitschrift für praktische Geologie* of 1906 sums up the available data and seeks to establish criteria for minerals of primary and secondary deposition. It must be confessed the two are often difficult to distinguish, as in Butte, for example. Changes in the primary vein deposits in depth are known to exist, and the whole subject needs more study. At present secondary sulphide deposits of chalcocite, bornite, and rich silver ores are well proved. Much less general seem to be the secondary sulphides of lead, zinc, and iron. Gold being soluble with difficulty migrates very slowly, but will do so if given abundant geologic time.

In the preceding remarks I have confined myself to chemical and mineralogical features of ore deposits. It is unnecessary to say that this comprises only half of our work. The form and structure of the deposits should of course be recorded for theoretical as well as for practical considerations. With more or less success this is always attempted. As examples of recent good work in this direction I should like to call your attention to a remarkable book issued in 1903 by the Austrian Government on the metasomatic lead-zinc mines of Raibl; it contains about seventy excellent chromo-lithographs of particularly good exposures of the deposits as recorded by the Government engineers. The recent Victorian reports on Bendigo and Ballarat veins are also models in this respect. Still another is shown in Spurr's treatment of the faulting of Tonopah veins.

But after we are done with the description of our deposits and with the explanation, if attainable, of the manner of mineral formation, the question of its ultimate origin always remains, that most difficult and unsatisfactory chapter to write, since it is in part based on hypotheses and suppositions. Whence came these solutions, these carriers of the

rarer metals? Aqueous deposition is universally accepted for the epigenetic deposition. We are all familiar with the theory of circulating and depositing or surface waters whose ablest exponent is Van Hise, and which found almost universal approval in the last years of the nineteenth century. The metals contained in the re-ascending surface waters were held by Stelzner to come from "indefinite depths," by Posepny to be extracted from the "barysphere," by Sandberger from the wall rocks of the deposits, by Van Hise finally by gradual solution of minute traces in the rocks during the descent of the waters.

Toward the close of the nineteenth century the brilliant suggestions of Elie de Beaumont of metal-bearing solutions separated from cooling magmas, dormant through many years and counting only a few not very aggressive adherents in France, seemed to rise from the past and were espoused in a spirited manner by Professor Vogt. Shortly afterward, during the first years of this century, American observers began to give consideration to it. The geologists of the Cordilleran region took it up with enthusiasm, as it seemed to explain so many of the questions which confronted them in a field where later metamorphic action had not dimmed the picture of the intimate and undissoluble connection of the precious metal deposits with the igneous rocks.

And so, in the study of genesis, the most remarkable tendency during the last few years has consisted in this rapid and widespread, though not unanimous acceptance of the magmatic theory, according to which all igneous magmas contain water and dissolved metals which upon the ascent of the magma into a zone of lessening pressure are given off, penetrate the surrounding rocks, and ascend to the surface as thermal springs. The results would in consecutive order consist of: (1) product of igneous differentiation in the magmas, (2) contact deposits at the point where the volatile substances left the magma, (3) deposits by magmatic waters on their way to the surface at greater or less distance from their point of origin and more or less mixed with surface waters. The theory that many hot ascending waters and much of their dissolved substances are of magmatic origin has been supported by some of the ablest men in geology, notably by Professor Suess. In recent papers Dr. Delkeskamp has attempted to establish criteria for the separation of the magmatic, or plutonic waters as many call them, from those of surface origin. It is impossible to peruse the literature of any country of the last few years without noticing the remarkable spread of this idea. It seems to pervade the whole atmosphere of research in economic geology, and finds expression among the workers from all countries. Perhaps it is most clearly expressed in the recent text-books. I refer first to the third edition of Professor Kemp's book on the ore deposits of the United States and Canada. Further to the somewhat later volume on mineral deposits by Professor Beck of Freiberg (translated by W. H. Weed), whose attachment for this theory and for the epigenetic mode of origin of most ore deposits is well known. The just completed hand-book of Professor Bergeat, based on Stelzner's earlier work, advocates magmatic origin for contact metamorphic deposits and for a large group of veins, although, in regard to the plutonic origin of modern springs, it still occupies a noncommittal position. On the other hand, it is to be noted that this author strongly opposes this mode of origin as applied to pyritic deposits and many others of the so-called bedded deposits. Beck, although an ardent supporter of the igneous theory, finds himself unable to accept such an origin for the middle Swedish iron ores, and it should be noted that Vogt himself, in spite of his predilection for magmatic theories, believes that this class of deposits was formed by original sedimentation. As explained above, other men have recently re-opened the argument and hold that here also igneous processes have been active.

In his great volume on metamorphism, issued in 1904, Professor Van Hise gives large space to the origin of ore deposits and his views represent plainly the present standpoint of the believers in the efficacy of atmospheric waters as originators of the greater number of ore deposits. While he recognizes that magmas contain waters and metals and that they are given off under favorable conditions near the contacts, he denies the propriety of referring the hot springs in volcanic districts to a magmatic origin, and believes that circulating surface waters have dissolved and re-deposited the metals contained in minute traces in the igneous rocks. It should be noted that Professor DeLaunay occupies a somewhat similar position. As expressed in his recent book on mineral springs he follows Daubrée in believing that most hot waters are of superficial origin, even where they occur in connection with igneous rocks. While not denying that volatile elements, such as carbon dioxide, arsenic, sulphur, etc., are derived from the magmas, yet he holds that the water is probably of superficial origin. It is an odd relation that the teachings of Elie de Beaumont should find but a partial acceptance in his own country, while in a modified form they have spread all over the world.

Perhaps the adherents of the magmatic theory go too far in some cases, as always happens in a new swing of opinion toward fresh and attractive views, but I believe it is safe to say that this theory has come to stay and that this and no other satisfactorily explains many ore deposits. Far be it from me to deny the power of surface waters, especially when somewhat heated by long underground passages, to dissolve and deposit material, and their work of concentrating metallic values is surely most efficacious in porous sedimentary rocks. Furthermore, it must be remembered that the magmatic waters constantly mix with those from the surface and that, as pointed out by many observers, this is one of the most potent causes for precipitation.

The work of Dr. Lane on the waters in the deep mines of Michigan has changed our views of the deep-seated rock moisture in showing that it con-

sists chiefly of strong solutions of chlorides, and, with this in view, attention should be directed to the mineralizing and especially the dehydrating power of such solutions.

The prevailing theoretical tendencies of the present day may be summed up as follows: We unanimously agree in seeking the ultimate source of the metals in the igneous rocks. We say that the rarer metals and other substances in aqueous solution emanate from the magmas during and after their irruption into higher levels of the lithosphere, and that minerals containing these metals are deposited along the pathway of the waters. We assert that heated atmospheric waters may search the congealed rocks, abstract from them a part of the small residues of the valuable metals and deposit them along their channels. We say further that metamorphism, when acting upon these igneous rocks, is a potent factor in favor of further concentration, aided by the moisture contained in the rocks.

We say finally that as erosion degrades the volcanic mountains and their ore deposits, and the fragments are carried down to form sedimentary beds, the heavy native metals such as gold and platinum, are concentrated into placers, and the baser metals are distributed as salts of various kinds throughout the beds. Atmospheric waters take up these particles into solution, and, aided by the influence of sulphur compounds and organic matter, concentrate the deposits in congenial places. Ore deposits of value resulting from chemical precipitates in sea or lake water, form only in case of abundant metals like iron. It is possible that in this summing up is reflected too much of my own individual opinion, but I believe that it represents fairly the general trend of modern thought.

Volumetric Determination of Magnesium.—The volumetric determination of magnetism is founded on the fact that if one mixes the latter with an excess of potassium arsenate of known quantity the arsenic may be determined iodometrically in the filtrate. To carry out the determination the solution of the magnesia salt is mixed in a 100 c.c. calibrated flask and titrated with a known volume of arsenate solution in excess and with an addition of 10% ammonia filled up to the mark. The magnesium arsenate is filtered off after standing at least three hours, repeatedly decanted. Evaporate as large a part of the filtrate as possible to dryness; dissolve the residue in a little water and wash with colder 50% sulphuric acid or with fuming hydrochloric acid afterward. If the solution is now put into a corked vessel with potassium iodide solution and mixed thoroughly there usually appears a precipitate. Should the latter fail to appear, then add more acid, and dissolve the precipitate in the required quantity of water. The titration of the free iodine follows with the sulphate. Each cubic centimetre of $^1/_{10}$ N. This sulphate at the end point requires less than for the titration of the employed amount of the arsenate solution, and corresponds to 1218 milligrams of Mg or 2018 milligrams of MgO.—*Chemiker Zeitung*, December 18, 1907.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

Evidence that an explosion of gases, which injured a miner, was aggravated by dust in the air, and which as a direct consequence of such aggravation became the proximate cause of the injury, was not unworthy of precedence as being unreasonable, as the weight to be given it was a question for the jury.

Davis *v.* Illinois Collieries Co., (Ill.) 83 Northeast. 836, Feb., 1908.

Where a coal miner fired a blast in an unskillful and unlawful manner, which caused an explosion of gas that was generated by a former shot, it was held not to preclude a recovery by him from the owner or operator of the mine for injuries caused by an aggravation of the explosion resulting from the air being charged with dust, if such explosion would not have injured him except for such aggravation.

Davis *v.* Illinois Collieries Co., (Ill.) 83 Northeast. 836, Feb., 1908.

A contract for the sale of certain mining claims provided for the payment of the agreed price in installments; the purchaser also agreed to perform certain development work, and the proceeds of any ore secured was to be equally divided between the parties; but if the purchase was consummated, any money paid to the seller was to be credited on the purchase price, and in case of a default in the payment of any installment the contract should be forfeited, and all sums paid should be treated as rent for the property. After the purchaser failed to pay an installment, the seller, after demand for payment, notified the purchaser that he elected to terminate the contract because of the purchaser's failure to perform the required development work. The seller obtained peaceable possession of the property and brought an action to quiet his title as against the contract. The court held that the seller's acts after the purchaser's default were consistent with an election to enforce the forfeiture; and that the purchaser was not entitled to recover the amounts paid by him under the contract, on the claim that there had been a mutual recission.

Ousler *v.* Thacher, (Cal.) 93 Pac. 1007, Jan., 1908.

A master is under no duty to warn or instruct a servant as to dangers discoverable by the exercise of ordinary care. And a servant engaged in blasting should know, or ought to have known, the danger in charging a hole with powder within a few minutes after springing the hole, and he was not entitled as of right to any warning on the part of the master, and that under such circumstances the master was not guilty of negligence in failing to instruct or warn the servant as to the danger incident to the work.

Hardy *v.* Chicago &c. R. Co., (Iowa) 115 Northwest. 8, Feb., 1908.

Equity will relieve from a technical forfeiture in the case of a mine lease where no pecuniary or substantial injury had resulted, and the performance by the lessee of all the covenants and duties imposed upon him by the lease, where the right of no third party had intervened.

Pheasant *v.* Hanna, (W. Va.) 60 Southeast. 618, Feb., 1908.

A written contract for the sale or option of coal in place must be duly acknowledged or proved by two witnesses under the statute of West Virginia, before it can be admitted to record by the clerk of the County Court of the proper county. And a contract of sale or option not so acknowledged or witnessed and improperly admitted to record and copied into the record book, was not a recorded contract, and was not notice to subsequent purchasers.

South Penn Coal Co. *v.* Smith, (W. Va.) 60 Southeast. 593, Feb., 1908.

THE CHURN-DRILL AS A MEANS FOR PROSPECTING.

Written for the MINING AND SCIENTIFIC PRESS
By E. E. CARTER.

The churn-drill has for many years been recognized as the cheapest and most economical means of finding oil and water, but it is only within the last few years that attention has been given to its application in mineral prospecting. This is largely due to the increase in the price of diamonds. Five years ago diamonds suitable for drilling purposes could be had for $18 per carat. They are now selling at $95, and the outlook is that the price may soon practically prohibit their use as a means for core-drilling. For this and for other reasons, inventive genius has been called upon to devise appliances whereby a core may be taken from the rock without the use of diamond. The inventor seems limited to two classes of machines, namely, to percussive drills, of which the churn-drill is a type, and to rotary drills, of which the diamond and chilled-shot drills are examples. The churn-drill is operated by means of a rope or cable, while the rotary drill must have hollow rods.

It has been proved by repeated experience that it is not practical to operate a percussion drill with hollow rods. This is due to the continual vibration, causing the rod to crystallize and break. Even should this difficulty be overcome, it is still evident that it is much more expedient and economical to reel in the tools by means of a rope than it is to draw and uncouple a great many rods. It has been found that it is not practicable to take a core more than 10 ft. long, and it is more satisfactory to see the core every three or four feet. Considering these reasons we find that the most satisfactory results are had with the churn-drill with its rope.

It is only recently that the core-barrel has been applied to the churn-drill. There are at the present time a number of simple and ingenious devices enabling the driller to get a satisfactory core that will furnish a valuable means for sampling and determining the value of a property. The churn-drill is manufactured in portable form, mounted on wheels, and so equipped with traction mechanism that it may be propelled by its own power over quite rough country. As to placer prospecting with these drills, it is unnecessary to say much. Anyone familiar with the placers around Oroville, California, knows what a valuable part these machines have played in proving the ground. It might, however, be mentioned that the drill is not only used to find the profitable gravel, but also to drill a series of blast-holes in front of the dredge for the purpose of loosening the ground for excavation.

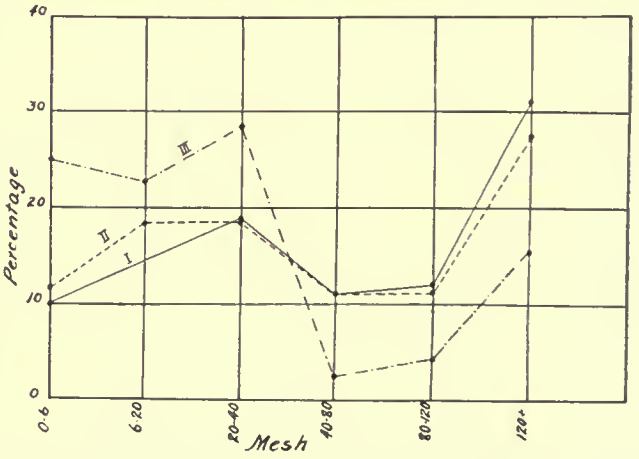
The value of a record of a drill-hole is in an inverse proportion to the value of the ore deposit. It must therefore appeal to us that its greatest efficiency is found in prospecting large low-grade deposits. Our attention is called to the methods used at Ely, Nevada, and at Bingham, Utah. At these places drills have been used to prospect the orebodies, and they are also being brought into service to drill blast-holes in their open-cut methods of mining, in which heavy blasts and steam-shovels are used. In the Missouri lead and zinc fields, as well as in the mines of the northern iron deposits, we find the prospecting largely done by means of the churn-drill. Very little advance has been made in opening up large low-grade gold mines along these lines.

In general we may sum up the churn-drilled borehole, as a means of prospecting, as follows: The value of the record is in inverse proportion to the grade of the ore; the assay is limited to the core and the cuttings; it is limited to all vertical work; it is necessary to put casing in all holes, but this may be withdrawn and re-used; the cost per foot is about one-third that of diamond drilling under the same conditions; the size of the hole is two or three times the size of the ordinary diamond-drill holes; the cost of the equipment, due to its simplicity, is comparatively small; it is possible to determine the dip, strike, and assay-value of the orebody and the country rock through which you will have to cut to reach the ore in running your main workings, thus making it possible to pre-determine the most suitable situation for your works, and to estimate the cost of reaching your orebodies.

As this method is becoming so favorably known and the results shown by some of the best mines in the country seem to confirm the opinion that this means of prospecting is proving effective, it seems probable that we may consider the churn-drill as a machine of more than ordinary importance for the future of the mining world.

Comparative Crushing Experiment by Rolls and Ball-Mill.—To determine the nature of the crushing by either of these machines the following experiments were made:

In experiment I of the figure, matte was crushed in a ball-mill to pass a 6-mm. screen; in II this mill crushed ordinary roasting sulphide. Note the close execution of the work in both cases. In III a sul-

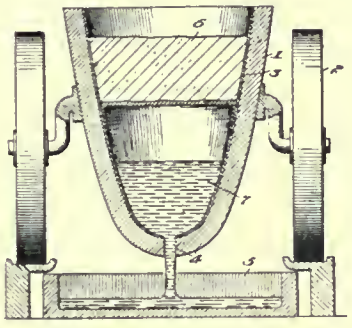


phide ore containing gypsum and pyrite was crushed by rolls to pass a slotted screen $^{3}/_{16}$ by $^{3}/_{4}$ in. From the graphic curves of the figure we note that a greater portion was coarse-crushed. In the case of both ball-mill and rolls we note a maximum at the size 20 to 40, and of that finer than 120-mesh, but it can be seen that the rolls make less fine than the ball-mill. A minimum amount of material is to be found between 40 and 120 mesh.

MINING AND METALLURGICAL PATENTS.

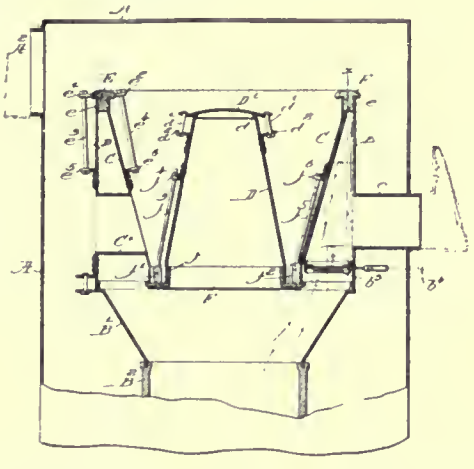
Specially Reported for the MINING AND SCIENTIFIC PRESS.

PROCESS OF PRODUCING SLAG-FREE FERROCHROMIUM.—No. 882,637. John B. Huffard, Ferris, West Virginia.



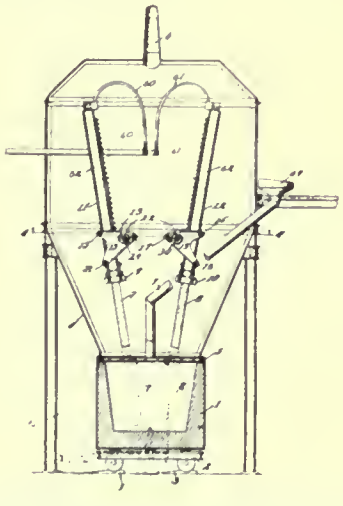
The process of producing metals free from slags of relatively high melting points, which consists in discharging the molten metal and slag into a vessel, allowing the metal and slag to stratify and the slag to solidify, and separating the molten metal from the solid slag.

FURNACE.—No. 882,616. Henry Bluhm and Joseph H. Regan, Boston, Massachusetts.



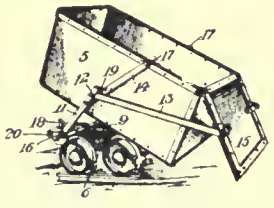
In a furnace, a heating surface comprising outer and inner walls, a central dome having a cap, a ring sustaining the lower end of said dome and fitting the lower end of said inner wall, said inner wall, ring, and dome each having ears, and tie rods to connect said ring respectively with the ears of the dome and inner wall.

ELECTRIC FURNACE.—No. 883,110. Herman L. Hartenstein, Constantine, Michigan.



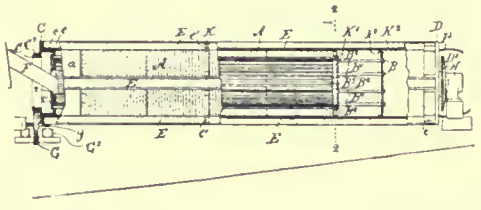
In an electric furnace, the combination of an inclosure constituting a furnace chamber, movable electrodes situated within said chamber, conductors leading into said chamber, and yielding connections between the electrodes and said conductors.

DOOR-OPERATING MECHANISM FOR ORE-CARS.—No. 884,091. George C. Johnson, Los Angeles, California.



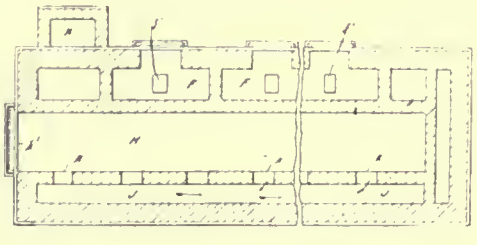
A composite lever for operating swing doors at the end of the body of ore cars or the like, comprising three members, these members being pivotally secured to each other at one of their ends, the other ends of these members being pivoted as follows, one to the body of the truck, one to the body of the car, and the other to the swinging door.

GOLD-WASHING SCREEN.—No. 883,974. William H. Roughsedge, Ottawa, Ontario, Canada.



In a screen, the combination with a head ring and a tail ring each having seats for longitudinal beams, longitudinal beams having their ends secured in said seats and connecting the said rings, a shoulder on said head ring to receive the end of the outer screening cylinder, a disc flange on said head ring to receive the ends of longitudinal screen bars forming the inner screening cylinder, a tread ring secured to said head ring, carrying rolls upon which the tread ring is supported, journal supports of said rolls, a bevel wheel on said tail ring with trunnion, a journal bearing for said trunnion suitably supported, a cross shaft suitably journaled, means for giving motion to said shaft, a bevel pinion on said gear, gearing into said bevel wheel, a plate ring secured to the longitudinal beams some distance from the tail ring and having secured in it the ends of some of the longitudinal screen bars forming the inner screen, a pair of tire-rings placed some distance from said plate ring and between which the ends of the shorter longitudinal screen bars are placed, an outer tire-ring in the same plane as the other two tire rings secured to the longitudinal beams and supporting the outer screening cylinder and stay bolts passing from the said outer ring to the inner ring, substantially as set forth.

FURNACE.—No. 883,916. Alfred Smallwood, London, England.



A smelting, crucible heating, and annealing furnace, comprising a fire grate, a horizontal combustion chamber in communication therewith, a heat chamber situated above the combustion chamber and communicating with the latter at the end remote from the fire grate, an annealing chamber situated adjacent the heat chamber and having a plurality of apertures through one of its walls, and means for selectively opening and closing the apertures of the annealing chamber.

MINE REPORTS.

BROKEN HILL PROPRIETARY, NEW SOUTH WALES.

The forty-fifth half-yearly ordinary general meeting of the Broken Hill Proprietary Co., Ltd., was held in Melbourne, February 28, 1908.

The chairman, Mr. John Darling, stated that last August everything connected with the company was in a most prosperous condition, and although then there were indications of prices being at their maximum, and that some decline might reasonably be looked for, no one anticipated that the markets for silver and lead would so seriously break. There are many circumstances responsible for the altered position. Primarily, no doubt the financial crisis in America, so strongly reflected in Europe, was a great factor, as it caused a contraction in trade and commerce, which at all times is quickly felt in such commodities as lead and silver. Although abnormal prices may not be again seen for many years, yet a steady market at about £14 per ton for lead, and 2s. 2d. per oz. for silver may be reasonably looked for. The silver market was largely affected by absence of rain in India, thereby restricting the demand in that country, and in consequence dealers in India and China took advantage of the position by selling forward, and no immediate relief was obtainable, as stocks on hand were large, with no demand.

The highest point reached for lead in 1907 was £22, and a sharp decline to £13 was recorded at the close of that year, being 40% from the maximum reached. Zinc, also, in sympathy, declined from £28 to £20 10s., or a fall of 27%. Under such circumstances it is not to be expected that, by comparison with the two preceding half-years, a satisfactory report can be shown, particularly as no compensating reductions in the costs of mining and treatment have occurred. The increased wages are still in force, and will not be disturbed until the period agreed upon has expired, when, if no improvement takes place, it will then be absolutely necessary to look for some relief in the lowering of present costs.

During the period under review the mine has not suffered from the effects of the fire, as the precautions taken by the provision and attention to water curtains have prevented any interference with the work of the mine. It has, however, necessitated a further expenditure of £3173, against £4498 the previous half-year, or a total expenditure to date of about £36,000.

The ore reserves have not been materially increased by new discoveries or developments. On May 31 last there were 2,955,000 tons, since which 312,158 tons of ore have been raised, leaving at date 2,643,000 tons, and this quantity gives two years' full output of 10,000 to 12,000 tons per week. Similar remarks were made in 1904, since which time new discoveries have been made, and it is quite probable that in this regard history will repeat itself. The quantity of ore raised for the period was 312,158 tons, being about 22,000 tons more than in the previous half-year, the average cost of mining, inclusive of development work, etc., being 15s. 8.41d. per ton, or about 1s. 1d. per ton more than the preceding period, about 9d. per ton of which is due to increased development and to diamond drilling, and the balance to slightly increased earnings of contractors, greater quantity of timber used, together with increased expenditure in water and sundry small items. With the prosperity that was enjoyed, the opportunity to push on with development and exploration was largely availed of, with an expenditure of £40,000, being the largest on record. The boring that was started at the 400 and 500-ft. levels from Block 14 main shaft, with the purpose of picking up the eastern lode revealed by the British mine workings in the vicinity of this company's Block No. 80, has now been stopped, nothing having been met with, and the same also applies to the boring from the 650-ft. level opposite Stewart's shaft, which was started with the same object. Besides this work, one small and two large diamond drills have been almost constantly at work, proving the ground in various places, boring in all 3056 feet.

At the 1200-ft. level the south drift was extended 140 ft. and the north drift 150 ft. (the last 110 ft. in country rock), disclosing a total length of ore of 1020 ft. on this level north of Block 10 boundary. The appearances at the 1200-ft. level are more satisfactory as the orebody, before pitching to the south, extended 400 ft. farther north than was expected from the indications at the upper levels. Shaft sinking has been carried on vigorously. The blind shaft in Block 11 having been sunk 145 ft., the total depth now being 1345 ft. Stewart shaft has been deepened to 1212 ft. Delprat's shaft is down 1302 feet.

The ore dressing mill has treated 298,327 tons of crude ore of a slightly lower grade than the previous half-year, and the recovery in lead in concentrate slime is about 50% higher, but about 33% lower in concentrate only, at an increased cost of about 5d. per ton, of which 3d. per ton was due to the additional cost of water. The re-grinding plant has now been erected and is treating about 300 tons of coarse tailing per day. The sulphuric acid plant has been enlarged, producing 2295 tons of strong acid as against 1133 tons the previous half-year, and has resulted in lowering the cost about 7s. 6d. per ton. The zinc plant has been worked to its fullest capacity, and has treated 175,021 tons, yielding 41,203 tons of concentrate. The concentrate averaged 42.36% zinc, being the highest average for a like period from this plant. The increased cost of 10d. per ton of tailing was due principally to the cost of re-grinding a portion of the feed, which is more than compensated for by the lead concentrate recovered by the tables.

Additions have been made to the electric power plant, air-compressors, pumping station, and new workshops, a water-softening plant, condensing plant (to meet emergency of drought), and an exhaust steam turbine and accumulator have been provided.

At Port Pirie the smelting plant has continued to do good work, and with the introduction of the 'Turbo' blower satisfactory results have been obtained, so much so that it promises to revolutionize the company's smelting operations, and will more than repay the cost in a short time. With some alterations in the furnaces, by increasing the length of the water jackets and the depth of the crucibles, it is expected that as much work can be done in four furnaces as was done by seven previously. Improvements have been made in the Huntington-Heberlein process by a new method of treating the material in the converters by cooling and then wetting until it contains 10% water, the result being that less lead is volatilized. The temporary machine, capable of treating 300 tons per day, was at first experimental, but has now proved so great a success that a permanent one is being prepared. Five new converters have been provided, making a total of 22. The total quantity of ore and slime treated at the smelting works for the half-year was 109,342 tons, together with drosses and flue dust 4656 tons, giving a production of 29,612 tons of lead, 1,976,078 oz. silver, and 1295 oz. gold, requiring as flux iron, limestone, coke, etc., 121,705 tons. At the zinc plant Mr. Arnemann is now actively engaged in erecting an up-to-date retort furnace, together with the necessary drying-rooms for retorts, and he expects to have the furnace finished ready for drying by March, and to produce by the end of June.

The scheme for an improved water supply for Broken Hill still occupies serious attention. The Umberumberka Amending Act on the lines indicated by the mining companies has been passed by the New South Wales parliament. The services of a hydraulic engineer have been secured, and after much investigation a site has been recommended for a suitable dam.

The net profit for the half-year is £137,642 0s. 5d., as against £308,238 8s. 2d. for the preceding half-year. The profit per ton of ore treated has been 8s. 9d. per ton, as against £1 0s. 9d. The liquid assets are £497,471 9s. 6d., inclusive of reserve and insurance funds, the two former standing at £225,000, and the latter at £35,000. Two dividends and bonuses to the extent of £288,000 have been paid during the half-year. The sales of lead have been 29,742 tons, of which 20,961 tons were to Europe, 5467 to India, China, and Japan, and 3314 tons in Australasia.

ON THE COUNCIL of the new Mining and Metallurgical Society of Ameriea are the following: H. S. Munroe, W. R. Ingalls, and J. R. Finlay, of New York; Robert H. Richards, of Boston; F. Lynwood Garrison and W. A. Lathrop, of Philadelphia; C. B. Dudley, of Altoona; Waldemar Lindgren, of Washington; L. S. Austin, of Houghton; G. S. Rice, of Chicago; Joseph Hyde Pratt, of Chapel Hill; C. R. Claghorn, of Tacoma; H. B. Patton, of Golden; S. B. Christy and T. A. Rickard, of San Francisco.

WE HAVE RECEIVED many letters recording the damage done to the business of legitimate mine promotion by the Yukon Gold flotation and Lawson's campaign of advertisement. It is stated that several important issues were killed by the timidity aroused by this unexpected association of so important a house as that of the Guggenheims with so notorious a *chevalier d'industrie*. Even unprejudiced observers were sorry to see recognized leaders in mining enterprise forming a partnership, indirect it may be, and implied rather than expressed, with a man who prostitutes the press to his stock-peddling campaigns. We yet hope to see a disavowal from Mr. Daniel Guggenheim and a confirmation of the gossip that the block of Yukon stock was optioned to another party, who was really blameworthy for enlisting the services of the champion bunco-steerer of America.

GOLD PRODUCTION on the Rand continues to advance, the output for the first quarter of the year being worth £7,124,117, or at the rate of $142,250,000 per annum. There are 8800 stamps dropping, as compared to 8540 a year ago and 6485 in 1905. Besides the increase in the number of stamps, there is an enlargement of production due to the use of heavier stamps and the supplementary grinding in tube-mills. Fully 75 of these useful machines are now employed. Another important factor in stimulating production has been the better supply of native labor; at the end of March there were 137,075 Kaffirs employed, as compared to 90,841 this time last year. This increment has done much to allay the anxiety caused by the repatriation of the Chinese coolies. Working costs are diminishing a little faster than the decrease in yield, so that profits are better in the cases of several mines. On the whole, affairs on the Rand wear a more cheerful look.

COMPANY PROMOTION is an integral part of the legitimate business of mining, and it is well that the fundamentals of this flotation process should be understood. Like the 'flotation' processes at Broken Hill, concerning which we have had some-

thing to say in a technical way, it is true of company promotion that it requires oil for smoothness and gas for stimulation. Joking apart, financial practices are as important, even to technical men, as metallurgical methods, and if they fail sometimes in making money honorably from applying their inventions it is due often to the misunderstanding of the proper steps to be followed in the devious ways of Throgmorton Avenue or Wall Street. Therefore the article by Mr. Henry A. Butters will prove useful and interesting. He writes as a man of authority, and not as a scribe, for he has initiated and organized important enterprises from New York to London, from Mexico to Geneva. A man that can make money by promotion and retain an honorable name must possess character and we listen to him with respect. Our readers will find that Mr. Butters covers the ground in a comprehensive way.

SILVER CYANIDE, as pointed out in the able scientific examination by Mr. W. A. Caldecott of the practice of cyaniding silver ores in Mexico, which appears in this issue, cannot co-exist in solution with more than a trace of sodium sulphide. As the solution of silver sulphide by sodium cyanide involves the formation of sodium sulphide, the disappointing results in leaching many silver ores are readily explained. No less interesting and important are the secondary reactions which, as Mr. Caldecott shows from careful experiments, may facilitate the solution of silver sulphide from its ores. Strikingly significant is the cycle of reactions to which Mr. Caldecott directs attention, occurring when lead is present. Introduced as oxide a reaction will take place with the sodium sulphide, producing sodium oxide and lead sulphide, which latter will at once react with sodium cyanide and free oxygen, forming the sulphocyanide with regeneration of the lead oxide. A small quantity of lead oxide will, by virtue of these cyclical reactions, protect the silver cyanide derived from the so-called free silver in the ore from being precipitated by the sodium sulphide which forms as the silver sulphide passes into solution. By throwing light on these reactions the article not only points the way to control of conditions for securing better economic results in a branch of cyanide treatment that has always been full of difficulty and discouragement, but it will suggest a promising line for further investigation by progressive metallurgical chemists.

The New Society.

IN this issue we publish the full text of the constitution and by-laws of the Mining and Metallurgical Society of America, as adopted at the organization meeting in New York on April 20. We are informed by telegraph that no changes of any importance were made at that time in the text of the constitution and by-laws, so that our readers can infer for themselves under what sailing orders the new professional ship is to go forth. We learn that the organization committee of the new Society held a conference with the council of the American Institute of Mining Engineers in the hope of effecting an affiliation, but nothing was done in this direction. Dr. Raymond, however, went so far as to say that the Institute would be willing to publish the papers of the new society at cost. Nor was it to be expected that a consolidation would be made; in fact, such a result would have prompted a strong doubt as to the necessity for a new organization. If the Mining & Metallurgical Society is to prove of service, it will be not by working on the same lines as the Institute, nor even on a parallel line, but by developing territory as yet not exploited. Most of the organizers of the new Society are members of the Institute. While it may be that there are members of the Institute who are inclined to criticize its administration, it is certain that the mainspring of the new departure is furnished by the desire to give the profession effective representation in a field of intellectual activity now entirely neglected by the Institute; in a word, the new Society will get scant support as a mere rival of the Institute, and half-hearted support if, even without intention, it should embarrass the Institute. What most of us, certainly those on this side of the continent, desire is to have a society that will crystallize professional practice, afford an opportunity for discussing ethical problems, enable the profession to give expression to its opinion on national questions, such as the mining law, legislation against fraud, prevention of accidents, and so forth; we want a society that can speak for the profession on such subjects as a proposed Mining Bureau, the work of the Geological Survey, the conservation of natural resources, and the many matters that affect the civic side of engineering life. All these subjects are tabooed by the Institute; under the dominating personality of its great Secretary the Institute has become a splendid publishing business and very little else. Let that work proceed without any attempt to duplicate it; certainly with no hope to better it. If the publishing of technical papers on the one hand and the ventilation of national, professional, and ethical questions on the other hand, are not kept separate by the two societies, we shall see a regrettable quarrel and an inevitable all-round failure.

We note that the constitution indicates the desire to 'stake out' a large claim, so as to cover the dips, spurs, and angles, besides any cross-veins of extra-lateral origin that may be discovered by deeper exploration. We take this as a desire to state comprehensive boundaries, so that any normal activity will not necessitate a re-statement of the position. Five principal objects are mentioned: the conservation of natural resources, the advancement of mining and metallurgical industries, the better protection of mine investors and mine workers, the increase of scientific knowledge, and the encouragement of high professional ideals. All of these are good and worthy purposes, but the fourth is one that can be shelved, and it must be set aside if it means camping on the trail of the Institute. There are many agencies for increasing scientific knowledge; the Institute is one of them; but there is no organization devoted

to the encouragement of high professional ideals, the better protection of mine investors and mine workers, and the like of that. Gentlemen, stick to your side-lines and let the Institute work the lode that it located, patented, and developed thirty years ago.

Mining and Gambling.

PEOPLE who gamble love to call themselves investors, but they rarely take the trouble to ascertain the result of their venture in advance, the fact being that long before their speculation will have run its course they intend to sell to someone else less well-informed or more adventurous. Thus in the case of the notorious Yukon Gold advertisement of the Guggenheim-Thompson-Lawson combination, the profits are stated at $38,000,000, to be won in 15 years. That looks like lots of money. But the company is capitalized at 3,500,000 shares of $5 each, or $17,500,000. Stock was offered at $7.50; on this basis the capitalization is $26,250,000. Allowing for a return of 38 millions in 15 years, with a 5% sinking fund re-invested at 4%, the net yield is only 4.65%, plus the principal. If we take Lawson's advice that the stock be purchased at $15 per share, or $52,500,000 for the whole, then the investor, who receives 38 millions in 15 years, will lose $17,500,000, which happens to coincide exactly with the nominal capital of the company; for if the $52,500,000 be invested today at 5%, with re-investment of dividends at 4%, at the end of 15 years the return would be just $17,500,000 ahead of the purchase of Yukon Gold at $15 per share. If all the income be used as a sinking fund for the redemption of the principal, then the final return would be $14.46, out of the $15 paid for the stock; and this makes no allowance for interest. If it be assumed that the property will return 38 millions in 15 years, and in the meanwhile yield 10% net to the investor, then each share of the 3,500,000 is worth $4.82, allowing for a sinking fund and re-investment as before. But the $38,000,000 is an estimate that includes "probabilities and possibilities" of an indefinite kind, and the analysis of the reports shows that, on an investment basis, there is an assurance of 19 million dollars being won in 9 years; on this basis the shares are worth $2.90 only, if a 10% yield be predicated, plus sinking fund as before.

Surely this is not without its suggestiveness. It does not point to mining as a poor investment, it merely emphasizes the fact that only clergymen and school teachers ever regard dealings in shares as other than highly speculative ventures. Because they are speculative they are not objectionable. Quite the contrary. Big risks bring big gains, but it is folly worn threadbare to buy stocks without accurate knowledge, on the expectation of selling to others during a boom, whether particular or general, and then to call such a financial adventure an investment. Don't play the fool and expect miracles to happen.

Another moral to be drawn from the episode is that capitalists, under the advice of experienced engineers, will speculate successfully in mines, but, not content with the slow return obtainable by actual exploitation, they turn around and, with the aid of promoters, whose only aim is to sell, they dispose of their holdings at a profit wholly unjustifiable, save on the score that to them that have shall be given, or on the basis that the inexperienced in finance must contribute to the knowing ones. This unloading on the public is the curse of mining, because, apart from the injury done to innocent people, it subordinates the technical features to the financial, in fact, to the predatory. By this trick of passing worthless mines onto the unsuspecting dabbler in stocks or of disposing valuable mines to the public at twice their real worth—so that in the end the result is much the same whether the mine be valuable or worthless—the actual operations at the mine or the metallurgical treatment of the product are belittled, the stockbroker becomes vastly more important than the engineer, Lawson is more effective than Perry. The profession suffers by being used for nefarious ends; the publicity obtainable through the press is prostituted to lying; mining is made a derision and a snare.

Bureau of Mines.

THE BILL for a Bureau of Mines was reported favorably, on April 16, back to the House of Representatives, with the endorsement of the Committee on Mines and Mining. It is uncertain what the next move may be, but the prospects are good for favorable legislative action. Care has been taken to avoid duplicating any duty that the Geological Survey is already authorized to perform. The committee says that the mere statement that "the mining industry adds annually to the wealth of the country a value of nearly two billions of dollars, and that this enormously valuable resource, second in value only to agriculture, receives substantially no promotion, no help, and no attention from the United States Government, ought to be argument enough for this bill." But beyond this consideration is the call for such Federal assistance to local authority as will lessen the appalling loss of life incident to labor in mines, especially in coal mines. The Bill asks for the establishment in the Department of the Interior, of a Bureau of Mines, to be directed by a Commissioner, to be appointed by the President, with a salary of $6000 per annum. The duty of this Bureau and its Commissioner shall be "to foster, promote, and develop the mining industries of the United States; to make diligent investigation of the methods of mining, the safety of miners, the possible improvement of conditions under which mining operations are carried on, the treatment of ores, the use of explosives and electricity, the prevention of accidents, the values of mineral products and markets for the same, and of other matters pertinent to said industries, and from time to time to make such public reports of the work, investigations, and information obtained as the Secretary of said Department may direct, with the recommendations of such Bureau."

Personal.

GELASIO CAETANI is at Monaco.

D'ARCY WEATHERBE is in Spain.

H. DEC. RICHARDS is at New York.

KARL EILERS is here from New York.

CURTIS H. LINDLEY is at Ely, Nevada.

W. J. LORING is at Denver, on his return to London.

LESLIE SIMPSON is on his way back to the Transvaal.

OSCAR H. HERSHEY is examining mines in eastern Oregon.

G. McM. Ross was in San Francisco several days this week.

HARMER C. SANDIFER is operating at Seven Troughs, Nevada.

W. H. WILEY is engaged as expert in mining litigation at Goldfield.

ALBERT ROBERTS has gone to Keen Camp, near Hemet, California.

ALBERT BURCH is examining mines in Siskiyou county, California.

W. M. KNOX has been drilling dredging ground near Folsom, California.

THEO. F. VAN WAGENEN is at Zacatecas, but will return to Denver shortly.

OTTO SUSSMAN now has an office at 420 Empire Bdg., Denver, as well as at New York.

E. H. MESSITER is visiting Oroville, on his return from Cananea and British Columbia.

V. P. STRANGE has returned to Salt Lake, after having visited Rawhide, Nev., and San Francisco.

J. JEROME SMITH has returned to Stockton from a visit to the Mother Lode, near Sonora, California.

CHARLES R. VAN HISE delivered the class-day address before the Michigan College of Mines on May 1.

LLEWELLYN HUMPHREYS has returned to Salt Lake from Nevada mining points, accompanied by L. EWING.

C. A. HEBERLEIN has resigned from the Compañia Metalnrgica de Torreón, and has gone to Zacatecas, Mexico.

JOHN DERN, president of the Consolidated Mercur Gold Mines Co., has left Salt Lake City on a four months European trip.

G. W. METCALFE, formerly with the United States smelter at Bingham Junction, Utah, has become superintendent of the Yampa smelter in Bingham canyon.

C. H. MUNRO, lately engaged professionally in Barranquilla, Colombia, has returned to San Francisco and will make his headquarters in the Crocker Building.

WALTER G. PERKINS, construction engineer and metallurgist for the Nevada Consolidated Copper Co. was at Salt Lake City recently, on his way to Butte.

M. A. NEWMAN, assistant general manager of the Minas del Tajo, is here. He will assnme charge of the Jesus Maria y Anexas and the La Piramida mines at San Jose de Gracia, in Sinaloa, Mexico.

JOHN P. COSGRO, mechanical superintendent American Smelters Securities Co., is seriously ill at St. Luke's Hospital, St. Louis, Missouri, with typhoid fever, contracted during a recent professional trip.

H. A. BUEHLAR has been elected Director of the Missouri Bureau of Geology, succeeding ERNEST R. BUCKLEY, who resigned. Mr. Buehlar is a graduate of the University of Wisconsin. He was at one time Assistant State Geologist of Missouri.

The Utah Society of Engineers, which has about 100 members, held its annual banquet in the Commercial Club rooms at Salt Lake City on April 21. The officers elected for the ensuing year were as follows: J. F. MERRILL, president; R. KLETTING, first vice-president; M. D. GROSH, second vice-president; D. MCNICHOL, secretary; HOWARD P. SAUNDERS, treasurer.

General Mining News.

ARIZONA.

GILA COUNTY.

Ore rich in gold and silver has been found at a depth of 10 ft. on the Clark lease of the Cole & Goodwin group of claims.

GRAHAM COUNTY.

The Gold Belt Co. has temporarily suspended, pending arrangements for construction of a small stamp-mill. The mill has not yet been purchased.

YAVAPAI COUNTY.

The 20-stamp mill at the Sultan will be moved to the Big Stick group, 20 miles northwest of Date creek.——It is reported that the largest orebody in the Octave mine is now being opened at the 1200-ft. level. The Cleopatra mine and smelter will start this week.——Work on the wagon-road for the Arizona Power Co., from Sycamore creek to the proposed power-plant on Fossil creek, is progressing rapidly, 200 men being employed.

CALIFORNIA.

BUTTE COUNTY.

The Blue Lead Mining Co. has been incorporated for the purpose of working the Blue Lead channel at Bangor. The company is now driving an adit from Honcut creek, so that when the Blue Lead channel is struck it may be properly drained.

EL DORADO COUNTY.

The owners of the Gilbert mine have already purchased a 10-stamp mill, which will be erected and put in operation at once.——Preparations are being made for the immediate equipment and operation of the Gold Hill mine, recently purchased by T. H. and Norval Douglas of Sacramento.——Good reports continue of the pay-shoot at the Fowler claim near Fort Hill. It is quartz ore and reported to be rich in gold.——Howard Misner has leased the Podoni mine in the Garden Valley district and will develop the property.——Green Bros. are erecting a complete 10-stamp mill on their property near Greenwood, where they have a body of good ore.

NEVADA COUNTY.

(Special Correspondence).—The Jenny Lind Co. has secured 30 additional acres of adjoining land by location and purchase. The new raise is expected to strike the channel in a few days.——The Golden Gate mine has been unwatered and driving east and west on the vein at the 400 level has started. The mill is running on ore from the upper workings. W. P. Martin is superintendent.——Development work will soon commence on the LeDuc claims on the eastern slope of Prescott hill. An adit will be driven and several men put to work. B. A. Penhall is superintendent. Some good ore has been struck in the Bear River Tunnel Con. mine. The vein is wide and of fair grade. Development work is going on steadily at the Spring Hill mine. A small force is working. The shaft at the Normandie is going down steadily. It is expected that ore will soon be encountered. High-grade ore is being extracted from several points in the Empire. About 300 men are employed.——The Brunswick mill is running steadily on good ore from the upper levels. A winze has disclosed good ore below the 300-ft. point.——The working force at the Union Hill mine has been increased. Two good veins are being developed.——The final payment has been made on the Mountain View mine in the Washington district and the property is now owned by the Miller M. Co. The Mountain View is producing steadily with good results. The new owners will work it on a more extensive scale.——The perpendicular double-compartment shaft at the Union Hill mine will be sunk to a depth of 1000 ft. early in June.——Sinking is progressing steadily at the Murchie mine. No further trouble has been experienced with the miners.——A large force is working at the Mountaineer and developing good ore. The main vein continues to show well.——Good ore has been developed in the Delhi. The working force will be increased soon.———Several Eastern mining men have been investigating mining properties in the Nevada City district during the past week.

Grass Valley, April 27.

The Champion and Delhi mines have been bonded to an English syndicate. The details of the transaction are not yet published, but it is believed that extensive improvements will be undertaken at both properties.——Development work is being resumed on the recent discovery of low-grade gold-lead ore near the Mason ranch, 14 miles from Grass Valley.——The ore-shoot has been reached in the Keller mine, a northern extension of the National and Culbertson at Graniteville.——It is reported that ore assaying about $15 per ton has been discovered on W. J. Mitchell's ranch, seven miles southwest of Grass Valley on the McCourtney road, near the junction of the Indian Springs road.

PLUMAS COUNTY.

The directors of the Newton Mining Co. have decided to continue mining operations on their property on Coquette

Slate Quarry, Placerville, California.

creek, near Buck's ranch. The work will be done by steam scrapers, and is only preparatory to operations on a large scale which the company expects to undertake next year.——The Oro Cobra Co. is driving an adit at the mine at Red Mtn., near Cisco.——The management of the Bellevue mine is sinking the shaft and blocking out ore preparatory to stoping.

SHASTA COUNTY.

Experimental work is being carried on continuously at Heroult under Professor Lyon of Stanford University. A large furnace will soon be ready for operation. This is built on the same general design as the small furnace which has given excellent results recently. The latter is being used for further experiments in the manufacture of ferro-alloys.——Construction work has been started on the by-product retort plant, and large quantities of wood are being delivered under contract by the Northern California Lumber Co. This plant will manufacture charcoal for the furnaces, and save tar, turpentine, acetate of lime, and other by-products resulting from the distillation of the wood. A. N. Johnson is in charge of the construction of this plant.——Shipments are being made from the Golinsky mine to the Mammoth smelter.——At Coram an increasing number of mechanics and laborers is being put to work on the side-

tracks, and other preparations are being made to start smelting operations shortly.

TUOLUMNE COUNTY.

The Tarantula, Omega, and Western Extension group, near the Eagle-Shawmut mine, has been bonded to C. A. Man and Joseph Russell. It is reported that the properties will soon be worked.——Spencer McCready has leased the property on the county road from Sonora to Shaws Flat. The property has an adit 900 ft. long. Development will be started at once.——The Gilt Edge placer mine, east of Sugar Pine, started work last week.——The Longfellow mine also resumed operations with a small force.

A large pocket has been found in the O'Hara mine. The value of it has not been determined, but fine specimens of gold have been taken out.

TRINITY COUNTY.

Thirty men are working at the Golden Jubilee mine on Coffee creek, and a quantity of ore has been extracted. The new mill is nearly completed and a cyanide plant is under construction. The old mill, consisting of two Huntingtons, is quite inadequate to treat the output of the mine.——At the Bonanza King from 30 to 40 men are employed. Ten stamps are working.——A gravity tram is being built at the Strode mine to transport ore to the mill.——A few men are working at the Yellow Rose of Texas mine near Carrville.

YUBA COUNTY.

J. C. Campbell has secured an injunction in the Superior Court to restrain the locators of the bonanza recently discovered in Brown's valley from removing ore. It is claimed that the discovery was made within the boundaries of the Campbell ranch.——The attorneys of the Anti-Debris Association have commenced suit against several people mining by the hydraulic process, and injunctions will be served against the defendants.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—An important discovery has just been made on the Colorado Central, Leavenworth Mtn. In carrying a stope from the Ocean Wave level, a streak of ruby silver and polybasite has been uncovered that measures from 12 to 15 in. wide.——Work has been resumed on the McKinley M. & M. Co., Lincoln Mtn. A streak of ore is being followed that measures from 12 to 18 in. wide. The average value of the product is $30 per ton in gold, silver, and lead. The adit is now in 390 ft.——Stoping is in progress upon the Clyde vein, cut 910 ft. from the portal of the Cully adit, a body of silver-lead ore being followed that is from 18 in. to 2 ft. in width. J. J. Culley is manager.——The men are within 15 ft. of breaking through to the Seven-Thirty shaft from the west Phillips drift, and great care is being exercised. In the old workings there are 10 miles of levels, drifts, and stopes, all of which are filled with water.——The machinery for the Linn Con. M. & M. Co. mill was all delivered on the ground this week. Frank Graham is now installing the equipment and hopes to have the plant running within two weeks. The towers for the aerial tramway have been put up and the cable, 3000 ft. long, will be strung next week. Ore is to be treated from the Mineral Chief mine.——The Georgetown adit, the portal of which is on Columbia Mtn., is being discussed. The adit should be 18,000 ft. long. The first 6000 ft. will pierce Columbia Mtn., and then turn toward Democrat Mtn. S. McKarahan is superintendent.——The Crescent M. & L. Co. has secured a lease upon the 15-ton mill below the Moline adit on Democrat Mtn. The machinery is being overhauled, while new equipment, consisting of jigs, tables, and re-grinding machinery, will be installed. The plant is to treat ores from the New Boston mine. A good force of men is being employed in blocking out the reserves. It is reported that this company has secured a lease upon the aerial tramway running from the Moline adit to the base of Democrat Mtn. G. D. Parks is manager.——G. W. Teagarden has been appointed manager of the Ramsdell G. M. & M. Co. Driving is in progress to the west on the Ramsdell vein and a streak of lead ore being followed that is from 18 In. to 2 ft. wide.——B. J. O'Connell, leasing on the Frostberg below the Victoria adit level, is sending out from 100 to 150 tons of ore monthly. The zinc product is being stored until the price of that metal makes an advance.——The Mendota mill is running three 8-hr. shifts, custom ore being treated exclusively.——Lawson & Co., leasing on the Millington, Columbian Mtn., are sending out regular shipments of high-grade silver-lead ore. Stoping is in progress upon a streak that measures from 12 to 16 in. wide that is rich in silver.——A deal is pending whereby the Eclipse adit on Saxon Mtn. is to be taken over by a syndicate of Chicago capitalists. This bore was advanced for 900 ft. a number of years ago, but owing to the death of the owner the property has since remained in idleness. A valuable group of claims is controlled, namely, the Magnet, Choctaw, Bellevue-Hudson, and Jo Reynolds. Steady shipments are being maintained from the Magnet vein, being developed through the Doric adit. A streak of ore is being followed in the stope that is from 1 to 4 ft. across, the average value of which is said to be $193 per ton in gold, silver, lead, and copper.

Georgetown, April 27.

GILPIN COUNTY.

The large electric pump for the Cook mine has arrived.——The Smuggler mill, near Rollinsville, will start soon.

OURAY COUNTY.

The Atlas intends to add 10 stamps to its mill.——The Treasury tunnel will be actively operated soon.——The Joker tunnel has successfully drained the Red Mountain group, and work will start as soon as the road is opened.

SAN JUAN COUNTY.

A 10-stamp mill is under construction on the Little Nations property on King Solomon Mtn.——The Hercules mill will start soon. During the last few months the capacity has been increased 50%, and when started will be worked with three eight-hour shifts. Further development will be undertaken the coming season on the Great Ohio property in Burrows Park district.——The Hamlet Co. plans to double the capacity of its mill in the near future.

SUMMIT COUNTY.

The Wire Patch mill at Breckenridge will open soon with electric power supplied by the Central Colorado Power Co.——The Emmet property on Yankee hill is being put in shape to run.——A new smelter is to be built by the International Mining Co., near Robinson.

TELLER COUNTY.

Three leasing companies are at work on the Mountain Monarch property on Raven hill.——Porter and Co. made a two-car shipment last week from the 400-ft. level of the Anchoria-Leland.——The Kaffirs Leasing Co. has leased the May Brewin, White & Blue, and New Turn claims, a continuous group of 10 acres.——Four cars a week are being shipped by Ramsey & Co., who have a lease on the Dead Pine dump.——Two cars of low-grade ore from the 400-ft. level of the Orphan Belle were shipped last week.——A company of Colorado Springs men has been formed to work some of the dumps near Gillette. They have leased the old Gillette cyanide mill and expect to begin operations next month.——R. S. Wallace has purchased the Anaconda mill.——The Julia V. on Beacon hill will begin shipments at once.

IDAHO.

BONNER COUNTY.

The Panhandle smelter at Ponderay has been leased for five years by the Montana Mineowners' Association, who will increase the capacity.

IDAHO COUNTY.

Placer mining has started in earnest and all properties report an abundance of water.——News comes of a big strike near Oro Grande, where it is reported a vein 14 ft. wide at a depth of 50 ft. shows free gold.——A new slime-plant at Buster was started recently.——A carload of ma-

chinery for the South Fork mine arrived at Stites last week.——The Coeur d'Alene group on Santa Ana creek has been bonded to a Spokane company, and work will be started as soon as the machinery can be transported to the property.——Construction of a 25-ton mill for the Meadow Creek mine is under way.

SHOSHONE COUNTY.

The Surprise Co. has remodeled its mill and resumed work. W. J. McLean is the new manager.——The Imperial, situated above Burke and west of the Copper King, will discontinue work on their upper adit and begin the driving of a 3000-ft. adit at a lower level.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—The development of new lands in the Galena and Badger camps has been especially noted during the past fortnight, and the activity throughout the district has been marked by extensive preparations for prospecting new ground. A discovery of lead ore in the city limits by Lynch & Williams on a lease on the corner of Wall and Sixth streets has created excitement owing to its excellent grade. The ore occurs in a boulder formation in lumps that are so large that one man can hardly handle many of the pieces until broken up.——Another find of importance was made upon the Ohio lease, where upon four lots a company of prospectors has developed a run of ore that mills 12% concentrate which assays 61% zinc. The ore was opened up on a lower level than had been previously worked.——The opening of the Wyandotte land west of the city to lessees has resulted in a number of new producers being developed. This land has just been drained by the erection of a large pumping plant and the assistance of a flume to carry off the waters of a small surface stream which previously discharged its waters into the underground workings through an old cave-in. The ground has been very productive in the 60-ft. levels, but the present work will be carried out at the 100-ft. level.——The Old Dominion Mining Co. has secured the plant known as the Newton, at Playter, and will at once begin the operation of this mine and mill. The recent high waters flooded the workings, and the drainage of the ground has been begun. The mill has been shut down for some time, during which the company carried on prospecting.——The Prudential Mining Co. has re-opened its mines and has started one of the mills. The ore for the present will be concentrated at one plant during the time necessary to open a deposit of sheet-ore recently discovered below the present level.——J. B. Rauch and associates have opened a new run of ore upon the Ohio land near the Central School building. The ore is zinc-blende and mills 10% concentrate.——At the Peacock camp, Dwier & Co. have opened a new body of free ore at 180 ft. The orebody is 20 ft. in thickness and driving has shown an extensive deposit. Two shafts are now down to ore, and when the underground development is carried far enough to supply the necessary ore a concentrating plant will be erected.——Prospecting has been in progress upon the land of the S. H. & S. Co. which has demonstrated an immense orebody, sufficient to run the plant for seven years. In addition to this development between the present mill and the river, the company is drilling some new ground northeast of the mill property.——The Federated Mining Co. has installed a new compressor plant to supply both its properties, and also finished the construction of a new milling plant. The ore will be supplied from a new shaft sunk southeast of the old mill, where at a depth of 180 ft. a rich deposit of zinc-blende was found. During the process of sinking the shaft a layer of water-bearing gravel was encountered which resulted in much damage to the shaft. The difficulty was overcome by puddling the shaft with portland cement.——The Cincinnati Mining Co. has just completed the development work necessary to begin active production. The new mill was but recently erected, and the company will begin its regular operation next month.

Galena, April 22.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The rapid development of the sheet-ground deposits west of Joplin has been responsible for the increased production of that camp during the past month. An area approximately 2½ miles long and 1½ miles wide has been thoroughly drilled and prospected, and in a few instances the orebodies developed to the producing stage. The principal work has been done upon the Luke, Glover, Schifferdecker, Hancock, Henderson, and Connor lands. Of these tracts the deposits upon the Luke and Glover lands appear to be most typically 'sheet ground.' The other tracts have deposits of sheet ground and also occasional soft-ground orebodies. To the soft-ground deposits belong the rich orebodies now being mined on the Schifferdecker and Henderson tracts.——The continuity of the sheet ground is shown by the drill records upon 240 acres of the Luke land, where 67 drill-holes were put down without a single blank. The deposits vary in thickness from 12 to 17 ft. Upon the Glover tract, 11 drill-holes penetrated orebodies 7 to 17 ft. thick. In a few of the holes two levels were discovered bearing good milling ore.——The Old Times Lead & Zinc Co. has drilled 52 acres adjoining this land, and the results demonstrate the entire

Slime Plant at Homestake Mill. Designed by C. W. Merrill.

tract to be underlaid with this class of ore. On a sub-lease to the Black Cat Co., two drill-holes showed deposits 22 ft. and 31 ft. thick. The development of this tract has been quickly accomplished and a concentrating plant will now be erected.——On a sub-lease of the Luke land the Cambria Mining Co. has developed an orebody at the 170-ft. level which shows a face 20 ft. thick. The ore runs 5% concentrate, 1½% being galena and the remainder zinc-blende. A concentrating plant has been erected and the property is now actively producing, though there is but 300 ft. of driving yet opened.——The Hero Mining Co. was the first company to begin active work in the new field. Upon its lease 30 drill-holes were put down without a single blank, and one hole showing a deposit 40 ft. thick. This discovery set in motion the prospecting that has made that portion of the district the most active of any camp in the field. Three shafts have been completed into the orebody and the ore is being concentrated upon a 200-ton plant. The ore from the 170-ft. level runs 5% zinc-blende.——On the north edge of Chitwood, two runs of sheet ore have been developed at 171 ft. and 199 ft. by the Pittsburg Mining Co. A concentrating plant has been completed and the plant will begin production at once. A tract of 16 acres has been prospected and thoroughly proved.——Developments of a similar character have added 60 acres to the producing territory of the new camp. This tract adjoins the Luke land just noted. The C. M. Sheldon Mining Co. has prospected the tract and sunk two shafts to the 140-ft. level, where the driving has since been done. Later drilling demonstrated a run of ore at the 170-ft. level, and two other shafts have been sunk to develop the last dis-

covery. The deposit varies from 6 to 15 ft. thick. The lease is now equipped with a 150-ton concentrating plant and is in operation.——A number of other companies and individuals are operating in this new territory, among the largest leases so far developed being that of Jarvis & Co. Upon this lease on the Reisling land 13 drill-holes have already penetrated ore.——A short distance north of Joplin, on the Hancock and Connor lands, Dewing and Allen have developed a body of ore 15 to 18 ft. thick and averaging from 16 to 18% concentrate. The ore was concentrated upon hand-jigs for some weeks, but a concentrating plant is now in course of erection.——The Henderson land, southwest of Joplin, has been one of the best developed soft-ground tracts. The Morning Hour, Big Three, and a number of smaller plants have become bonanza producers.

Joplin, April 28.

MONTANA.

BEAVERHEAD COUNTY.

The Dillon-Argenta Co. put in a new steam-pump and has drained the workings and will at once sink the shaft deeper. It is possible the company will erect a cyanide plant in the near future.

FLATHEAD COUNTY.

It is reported that both the Silver Crown and Porcupine will install new machinery on their properties at Granite Creek.——The old Bear Creek placer, near Libby, has been purchased by Spokane people and will probably be worked.

NEVADA.

ESMERALDA COUNTY.

It is reported that a custom mill will shortly be built at Reservation.——Knierim & Sons report encouraging prospects at their gold claims near Reservation. Two shafts are being sunk and both are in fair quality ore.——The Yerington B. C. Co. has purchased a group of eight copper claims from Gilmore & Frederick, and will start development at once.——The total shipments from Goldfield mines last week were 1940 tons, valued at $128,575, or an average of about $66 per ton.

HUMBOLDT COUNTY.

A rich strike is reported on the 165-ft. level of the Mazuma Hills, at Seven Troughs. The vein is said to be 7 ft. wide, and the best of it shows free gold. A number of new leases in the same neighborhood are reported.

CHURCHILL COUNTY.

J. F. Hicks has taken a lease on the Dromedary Hump at Fairview and will start at once with two shifts to sink the shaft to the 250-ft. level.

WHITE PINE COUNTY.

A test run of 100 tons of ore was made last week at the concentrator of the Steptoe Smelting Co., with entire satisfaction to the management.——The White Cloud Co. reports satisfactory progress on the development of its property near the Utah line.

SOUTH DAKOTA.

LAWRENCE COUNTY.

Increased activity is reported at the Homestake. Electricity is being installed in the Pocahontas mill, and the re-grinding plant and a new foundry are under construction.——An 8-ft. vein of rich gold ore was struck in the 300-ft. level of the shaft in the old Cooper ground in Ruby gulch on the property of the Hercules Mining Co.

UTAH.

JUAB COUNTY.

The Raymond-Illinois is replacing the engine which was wrecked last week.——The Yankee is shipping.——The Tetro is working two shifts.——The two large compressors for the Colorado have arrived.——Rich silver has been struck between the 1700 and 1900-ft. levels of the Gemini.——The Knight smelter will be started as soon as the power line is completed.

SALT LAKE COUNTY.

The Utah-Apex Co. has let the contract for driving the Parvenue adit, for the purpose of developing their property as well as providing an outlet for the ore from the Apex mine.——Two shifts are at work on the Butler-Liberal property, opening up new country.——Two new veins have been struck on the Central-Standard Co., one of copper and the other a lead-silver vein.——The Ute copper properties are being developed, two shifts being at work driving the Copper Hill adit.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—J. F. Eisom and M. F. Doherty, of Louisville, Ky., have been visiting the Pearl Con. property, in Republic camp, looking into an investment in the Syndicated Deep Mines, Inc. J. L. Harper reports that satisfactory arrangements have been made for financing his project, and that Judge Utz of Indiana, C. C. McChord, and several southern people have become interested and will visit the mines with him in a few days.——The La Fleur Smelting Co. has been incorporated with 1,500,000 shares at a par value of $1 each. Danville, Wash., is the principal place of business. Two-thirds of the stock has been placed in the treasury. Assessments may be levied up to 5c. per share. Two groups of claims are owned by the company, the first being the Telluride, Jim, and Anaconda, and the other the Cuba, Last Chance, Cumberland, and Mountain Lion Fraction, all situated on the northeastern slope of La Fleur Mtn. Negotiations are afoot for the purchase of six more claims. On the Cuba group are two shafts, 60 and 90 ft. deep, respectively. From the bottom of the latter a cross-cut has been driven eastward and another westward which intersects a cross-vein about 15 ft. wide at 40 ft. from the shaft. The ore of both veins is of the same character and assays 2½% copper, $4 to $5 in gold, and 2 to 3 oz. silver per ton.——The Humboldt Mining Co. of Keller district is applying for U. S. patents for the Humboldt group of claims.——There is considerable ore blocked out in the mines of the South Half group of the Colville Mining & Smelting Co. at Park City. The machinery and equipment for the smelter plant are on the ground and will be installed as soon as the snow goes off.

Republic, April 25.

OKANOGAN COUNTY.

The Ruby Mining Co., on Mt. Chopaca, is shipping two carloads of ore per day. The Mountain Sheep, an adjoining mine, has begun shipping; also the Nighthawk company on the opposite side of the Similkameen river.——In the lower adit of the Q. S. mine the vein has been crossed about 300 ft. of ore assaying 4% copper. A power plant on Salmon creek has been completed.——The Palmer Mountain Tunnel & Power Co. is employing 40 men and will put on about as many more by May 1. The mill is being erected and all machinery is on the ground. The water will be supplied by a pipe-line, now under construction, from Touts Coule creek. The adit has been driven 4600 ft. and lighted throughout with incandescent lights. Of the large number of veins intersected no one knows the assay-value of the ore but the company and trusted employees. There are some big iron sulphide veins on the mountain ahead of the adit, and it is believed a consolidation will be the final outcome.——The last report from the Butcher Boy mine, at Chesaw, says that a 30-in. vein of rich ore, some of the best yet encountered, has been developed on the 100-ft. level. No assays have been reported.——The Grant Con. Mining Co., at Chesaw, has driven the No. 2 adit on the Grant mine nearly 850 ft. and cross-cut 80 ft. of the second vein. A body of ore 30 ft. wide assays from $21 to $37 per ton, mainly copper and a little gold. From surface workings on this vein, 35 ft. deep, 180 tons of ore shipped to the Granby smelter gave returns of $19 net per ton, of which the gold contents were $4 per ton and copper $15. The first vein intersected in the No. 2 adit is reported by one of the leading stockholders to be 45 ft. wide and to have an average assay value of $15 per ton.——The operation of the Molson company's mill is retarded on account

of scarcity of water, but it is expected the supply will soon be increased by the melting snow and enable it to run to its full capacity.——Lumber for new buildings and flumes has been ordered for the Bethel group of placer claims on Mary Ann creek, six miles northeast of Chesaw. Preparation is being made for extensive washing of gravel the coming summer.——The shaft on the Copper Matte mine, near Loomis, is being sunk, under contract, to the 200-ft. level.——At the Lucky Knock mine, on Whitestone Mtn., the adit is in 116 ft., with about 125 ft. farther to run for the vein, which at the surface shows 5-ft. width of stibnite. ——The Apache mine, near the Nespelim Indian Agency, is getting ready to ship 50 tons of rich sulphantimoniate ore to the Tacoma smelter. This property may make regular shipments if obstructions in the Columbia river are removed, so as to admit of steamboat navigation from the Apache landing.——In an adit driven since last November by the Antimony Queen Mining Co. on Gold creek, Twisp district, a 43-in. vein of stibnite has been encountered at a vertical depth of about 150 ft. A small smelter plant is being established on the Dixie Queen group, on which the strike was made.

SPOKANE COUNTY.

(Special Correspondence).—A deal between the Montana Mineowners' Association and the Idaho Smelting & Refining Co. has been made here, by which the former association takes over the old Panhandle smelter at Ponderay, Idaho. This has been pending for several months, during which time several conferences have been held in New York, Helena, Spokane, and the Coeur d'Alene between J. Herbert Anderson, controlling owner of the plant, and representatives of the Montana mine owners. By the closing of this deal W. A. Clark, W. G. Conrad of Great Falls, Montana, Marcus L. Hewitt, E. A. Spriggs, Thomas L. Greenough, owner of the Snowstorm, and others, acquire immediate possession of the smelter on a five-year lease and option. The plant has been closed since the flurry last fall, although it has been undergoing extensive repairs during the last few months in expectation of being operated this spring. It was begun six years ago, but was not completed till J. Herbert Anderson and associates bought the control in the Panhandle Smelting Co., which owned the plant a year ago, and completed it, at a cost of $40,000. A trial run of six months was made on Montana and Coeur d'Alene ores, and was stopped only with the general depression and scarcity of money last fall. In January the old company capitalized at $5,000,000 was reorganized under the name of the Idaho Smelting & Refining Co., and the capital decreased to $2,000,000. At that time, it was expected to blow in one of the furnaces by the middle of February, but with the organization of the Montana Mineowners, following the visit of J. H. Callbreath, the secretary of the American Mining Congress, an effort was made to join the Montana men who had subscribed $100,000 for an independent smelter, and the matter was taken up with the gentlemen named above. On April 16 the deal was closed, and the new directorate chosen, which consists of J. Herbert Anderson, president; Marcus L. Hewitt, Basin, Mont., vice-president; S. B. Phillips, Spokane, secretary and treasurer; A. E. Spriggs, Helena, Mont.; W. G. Conrad, Great Falls, Mont.; T. L. Greenough, Missoula, Mont., and Albert Wunderlich, St. Paul, Minn. C. C. Titus, formerly in charge of the East Helena plant of the American Smelting & Refining Co., will take immediate charge of the smelter at Ponderay and begin operations. The name of the new company will be the Montana & Idaho Smelting Company.

The Ponderay plant is most favorably situated for the economical assembling of ores and fluxes. Through the townsite on which the smelter is built run the Northern Pacific main line, the Great Northern main line, and the main line of the Spokane International. By means of these roads the coke from Fernie, B. C., the copper and other ores from Montana, and the silver-lead ores from the Coeur d'Alene can be brought by direct haul to the company's bins. It also owns a steamer and barges on Lake Pend d'Oreille for the transportation of iron and lime from its own deposits down the lake. In addition to these features in its own favor, it will be the means of giving a market for many small mines of the Coeur d'Alene which have heretofore been handicapped by the high charges of the trust smelters. Many small mines along the lake which are hardly past the prospect stage will also be afforded the chance of development, and several of these now have ore sacked ready for the furnaces of the smelter. The plant is at present of 250 tons daily capacity. This will be at once raised to 500 tons, and to 1000 before the close of the summer. Facilities for the smelting of copper will also be added later.

Spokane, April 25.

CANADA.

ONTARIO.

The long idleness of Anaconda and many other copper mines in the West, which turn out a large amount of silver as a by-product, has caused active competition among smelters for the Cobalt silver ores. More smelters are now bidding for ore from the Cobalt mines, and in consequence the producers are enabled to obtain more satisfactory prices. Since Jan. 1 the following smelters or smelters' agents have been regular buyers of ore from the Cobalt camp: The Canadian Copper Co., Copper Cliff, Ontario; Del Oro Mining & Reduction Co., Del Oro, Ontario; Consolidated Mining & Smelting Co., Trail, B. C.; American Smelting & Refining Co., Perth Amboy, New Jersey; U. S. Metal & Refining Co., Chrome, New Jersey; Pennsylvania Smelting & Refining Co., Carnegie, Pennsylvania; Anglo-French Nickel Co., Swansea, Wales; R. C. Farrell & Co., Glasgow, Scotland; and the Beer-Sandheimer Co., Hamburg, Germany. According to the weekly report of the Canadian Bureau of Mines, the principal shippers to these smelters since Jan. 1, with the amount of their shipments, have been as follows: Buffalo, 517,520 lb.; Conlagas, 380,910; City of Cobalt, 228,080; Foster, 168,600; Kerr Lake, 330,710; Temiskaming & Hudson Bay, 539,000; Temiskaming, 237,250; Tretheway, 487,116; O'Brien, 1,448,190; La Rose, 1,437,252; McKinley-Darragh, 1,002,400; Nipissing, 943,430 lb. of ore, and Cobalt Central, 136,310 lb. concentrates, equivalent to 1,090,480 lb. ore.

BRITISH COLUMBIA.

Following is the tonnage of ore shipped from and crushed at the mines of Rossland for the week ending April 18, and for the year to the same date:

Mine.	Week.	Year.
Centre Star	3,100	53,018
Le Roi	1,365	26,534
Le Roi No. 2	550	9,565
Evening Star	....	428
Blue Bird	....	30
California-Giant	....	60
Totals	5,015	89,673

At the smelter of the Consolidated Co. there was received during the past week 5839 tons of ore. Besides the ore from Rossland, shipments from other mines were received as follows: St. Eugene, 445 tons; Snowstorm, 919; North Star, 36; First Thought, 292; Standard, 45; Rambler-Cariboo, 22; Vancouver, 20; Arlington, Slocan, 18; Ruth, 39; Whitewater, 21; Hewitt, 22; Silver Cup, 33; City of Cobalt, 62; Nancy Helen, 41; Maggie, 3 tons.——At the Granby smelter at Grand Forks there was received during the week 22,239 tons of ore from the Granby mines at Phoenix. The receipts at the Le Roi smelter at Northport during the past week consisted of 1365 tons from the Le Roi mine. The total smelter receipts at the three plants at Northport, Grand Forks, and Trail were 28,942 tons. The district shipments were divided as follows: Boundary, 22,329; Slocan-Kootenay, 1588; Rossland, 5015 tons.——A well defined ore-body has recently been uncovered on the Gallagher property, near Ainsworth. The vein is 3 ft. thick and is soft iron carbonate carrying silver and gold. It is believed that this body is the source of the high-grade ore shipped from this mine in 1899.

Special Correspondence.

LONDON.

Sons of Gwalia.—Mount Boppy.—Spanish Operations of John Taylor & Sons.—Hand-sorting and Concentration.—Conditions in Western Australia.

The Sons of Gwalia mine in Western Australia continues to make a good profit on the comparatively low-grade ore now found in the mine. During the year 1907, 156,034 short tons were milled, yielding 33,072 fine ounces of gold. The cyanide plant produced 22,982 oz., making the total yield 56,054 oz., which is at the rate of 30s. 6d. per ton. The total income was £238,350, and the working expenditure £130,073, the latter corresponding to 20s. 1d. per ton. In addition, £38,244 was spent on mine development, construction, and equipment. After paying London expenses, income tax, etc., a net profit of £61,967 was made, and dividends to the amount of £65,000 distributed, being at the rate of 20% on the capital. The ore reserves represent about two years' supply, and development work continues to open up the mine in a satisfactory manner. Owing to the recent developments in the south end of the workings, and the southerly strike of all the known ore-shoots, it has been considered advisable to take up further ground to the south in order to protect the pitch of ore-shoots in that direction.

The itemized costs of working are given very fully in the report of the company, as is the case with all companies managed by Bewick, Moreing & Co. It is not my intention to refer to these in detail, but I wish to enlarge on a subject raised while discussing the report with an American mining man now visiting this country. This is the use of the words 'mill' and 'milling,' a point in nomenclature where we might introduce uniformity. In America the word 'mill' includes the whole of the crushing, concentrating, and extraction plant; while elsewhere the tendency is to confine the word to the stamp-mill. For instance, in this Sons of Gwalia report, the cost of treatment is subdivided into the following sub-heads: Rock-breaking, ore-transport, milling, concentrating, roasting, cyaniding, fine-grinding, filter-pressing, etc. The word 'milling' is restricted to crushing and recovery by amalgamation in a stamp-battery. In England we do not as a rule refer to a cyanide mill, or a concentrating mill, preferring to use the word plant. But there are many differences between English and American terms.

There is an idea in America that John Taylor & Sons are almost entirely connected with Indian mines. This is of course a huge mistake, both as to the past and the present. This firm has two mines in Australia, one the Mount Boppy in the Cobar district of New South Wales, and the Tasmanian in Tasmania. The Mount Boppy makes an excellent profit out of low-grade ore, and it is interesting to compare the results with those at the Sons of Gwalia. I would parenthetically remark that comparisons of this sort are misleading and dangerous. The ore treated during 1907 was 76,339 long tons. In the stamp-mill 10,329 oz. of fine gold was won. By cyaniding 46,134 tons of tailing 11,542 oz. was recovered, and in the slime plant 7583 oz. was obtained from 29,925 tons of slime. In addition, 2147 oz. was recovered from 302 tons of concentrate. The total production for the year was 31,601 fine ounces, which represents a return of 8¼ dwt. per ton of ore crushed. The total income was £133,121, and the expenses in Australia and London, £67,023. Out of this £57,475 has been distributed as dividend, which is at the rate of 47½% on the capital of £121,000. The expenditure on capital account during the year was £8313. In the case of the Sons of Gwalia no expenditure is charged to capital, but the whole is included in the current expense, so that the total profit for the year is not reckoned on quite the same basis. The mine continues to open up well, and on Dec. 31 the ore reserves amounted to 193,858 tons, which is nearly three years' supply. The report issued by the company is as complete as that of the Sons of Gwalia, if not more so. Since the formation of the company in 1899, progress has been uniform, and from 1903 onward the dividends have risen gradually from 35 to 47½%. The total production of gold to date has been 144,081 fine ounces, realizing £589,960, while the amount distributed as dividends has been £262,282. This is an example of economical administration in the treatment of low-grade ore that compares favorably with any similar mine in Australia.

Another of John Taylor & Sons mines is in Spain, ten miles from Cordoba. This is the Cerro Muriano, a low-grade copper property. It was acquired five years ago and has been opened up by Henry F. Collins. For some time Capt. Tamblyn, who is now manager of East Pool in Cornwall, was the director of underground operations. The company is further strengthened by having William Frecheville as chairman. It has by no means been an easy mine

Western Australia.

Conditions in Western Australia.

The Sons of Gwalia mine is in Western Australia, and I have had occasion to refer to the conditions there. Mr. Hamilton Smith, who has been in charge of the Sons of Gwalia mine for many years, has just returned to Australia, and I have had a talk with him. He says that the labor conditions are very bad, and that the men are not working more than half time. The cost of living is very high, and the men are not earning enough to live on. The mine is working at a loss, and the company is trying to reduce the cost of production. The mine is now working at a depth of 1,000 feet, and the ore is getting harder and harder to mine. The company is trying to open up new ore-shoots, but so far without success. The mine is now working at a loss of £1,000 a month, and the company is trying to reduce the cost of production. The mine is now working at a depth of 1,000 feet, and the ore is getting harder and harder to mine. The company is trying to open up new ore-shoots, but so far without success. The mine is now working at a loss of £1,000 a month, and the company is trying to reduce the cost of production.

to open up, and the financial resources needed increasing recently. Before settling upon the method of raising new capital the advice of another mining engineer, Alexander Hill, was taken. His examination has proved that there is ready for stoping 100,000 tons of ore carrying 2¾% copper. He estimates that the working cost in producing the copper will be 17s. per ton of ore, if 150 tons per day be dealt with. The monthly output of copper would be 103 tons, which at £55 a ton should realize £5665. The working profit would then be about £1400 a month. A 100-ton unit of the plant has been erected, and the smelter is now being constructed. The funds being raised will be devoted to the provision of further plant and the continued development of the mine. With this object preference shares are being issued in order to raise £56,250. The directors and their friends have already subscribed for nearly half the issue, and the remainder has been underwritten. The terms on which the issue is being made are onerous, and show how difficult it is nowadays to raise money for mining operations. The capital issued hitherto consisted of £225,000 in 225,000 shares of £1 each. In order to raise additional

capital 260,000 new preference shares of 6s. each have been created. These preference shares carry the right to all profit distributed as dividend up to the sum of £150,000 in the aggregate in any year, and to one-half the surplus so distributed in any year; also in the winding up they are entitled to £150,000 out of the assets before any payment is made on the ordinary shares. Mr. Hill makes some interesting remarks regarding the relative value of hand-labor and machinery. To an American it may seem strange that Mr. Hill should recommend that concentration should be effected as much as possible by hand-sorting, to be done by women and children, and that only the refuse from such selection should be sent to the concentrators. But this advice is given by a mining engineer who knows mining conditions in all parts of the world, and it is to he assumed that he speaks out of an experience of economies achieved in widely separated mining regions.

A late publication from the Western Australia Mines Department gives full details of mining operations in that State during 1907. The number of men working totaled 18,548, including 1523 diggers. Out of this number 5646 were working in the Kalgoorlie district, where the mines in 1907 treated 1,630,000 tons of gold ore, valued at $19,-

Kalgoorlie.

967,000, while the grand total to date is $199,672,000. The tonnage treated in all mines in the State amounts to 260,000 monthly. Other minerals produced in 1907 were: 1623 tons of black tin, worth $793,000; 18,978 tons of copper ore, worth $900,000; 142,372 tons of coal, worth $275,000. Apparently there was no production of tantalite from the Greenbushes field in the southwest, where it occurs with the tin. In 1906 the production of tantalite was 88 tons, worth $6[illegible]. During February there were no developments of much importance on the Golden Mile, except that better ore was struck at the 900-ft. level in the Perseverance; and the Horseshoe had an encouraging strike in the bottom level. The value of the ore at the 2200-ft. level in the Great Boulder keeps high. The February output from all mines in the State was valued at $3,180,000. January dividends were $1,025,000; February, $38,500; March, $680,-000. Many attempts have been made to test at greater depths in the north end of the field, that is, three miles from the big group. This part is rather different to the other belt, as the lodes are mostly quartz in diorite. Several companies have failed to make profits, although a number of tributors are doing fairly well. Several public meetings have been held, and the Minister for Mines was asked to grant a subsidy and erect a sulphide reduction-plant in that district, but he was not impressed with either scheme. It appears now that something will be done with local capital. Rich spots are constantly being struck there, but it does not seem as if permanency is assured.

The water consumed in February by the Kalgoorlie mines amounted to 28,325,000 gal. The Mines Water Trust pays the Government $1.20 per 1000 gal. for ordinary purposes, and for pumping the residue away from the mills the price is only 36c. per 1000 gal. The day of conveyor belts for making high and dusty dumps with mill tailing is nearly ended.

DENVER, COLORADO.

Progress in San Juan District.—Conditions at Leadville.—Trial at Durango.—Cripple Creek.—Damages Awarded United States Reduction Company.—Tunnel Scheme at Granite.

Weather conditions are such that practically all the properties in the San Juan district that are to be worked this season are active. The tramways wrecked by the snow-slides of the early spring are being repaired, and the numerous mills start as fast as water becomes available. The properties along the line of the new railroad from Silverton to Red Mountain are stocking ore while awaiting the completion of that important spur line. A new mill has been contracted for by the San Juan Smelting & Refining Co. for its Henrietta mine. The Colorado Iron Works Co. is to do the work. The Green Mountain Mining Co. of Silverton has paid most of its debts and resumed operations with a small force.

The Leadville miners are still working with very small forces. In the downtown section all the shafts are idle. The low price of lead and zinc keeps this camp from producing its usual tonnage. From the surrounding district, however, much ore is being hauled in as the roads become passable. Work on the Dinero tunnel is progressing rapidly. Lessees are advancing the old Garibaldi tunnel at the head of California gulch, and a small vein has been cut. Present conditions indicate a dull season. There can be no improvement unless the metal market advances.

The trial of Joseph Vanderweide and William Mason for the murder of Joseph Walker, United States secret service agent, is in progress at Durango. The plea is self-defense and justification. The case is being fought bitterly on both sides.

Several new and important finds have been made by lessees in the Cripple Creek district during April. A prospecting permit has been granted by the Buffalo & Cripple Creek Gold Mining Co. to a party of local miners who contemplate work on the Newell tunnel in Grouse Mtn. The property, which is very low in grade, has been idle for several years. The Franklin Leasing Co., which secured a lease on the entire holdings of the Gold Sovereign Co. from the former management, and then had to defend its rights in court against the new managemnt, has its affairs settled and is shipping ore. The Elkton Con. M. & M. Co. has paid its regular 1c. bi-monthly dividend and an extra ½c. divi-

dend. The total dividends of the company to date amount to $2,079,640. A new organization, known as the Colorado Milling Co., has been incorporated, with a capital of $20,000. Leases have been secured on the Kimble dump and the dump of the old Gillett cyanide mill. The Gillett plant will be used for treating the rock from the dumps named.

The United States Reduction & Refining Co. has been awarded $60,000 in its suit against the Denver & Rio Grande Railroad Co. The suit, claiming $250,000 damages, was instituted as a result of the burning of the reduction company's National mill at Florence two years ago, the mill being set on fire by sparks from a passing engine.

Much work is going on in the vicinity of Idaho Springs. The Black Eagle mill on Chicago creek has been remodeled and started at full capacity. Repair work is in progress on the Salisbury mill, belonging to the Stanley Mines Co. A test run is to be made on the ore from the mine. The Lone Tree property at Freeland has been taken over under bond and lease by E. M. Moscript and associates, and they have started work in the Teller tunnel. Work has also been resumed on the Rockford tunnel. A raise is being made from the tunnel to the old workings of the Donaldson mine.

A statement issued by the board of directors of Stratton's Independence, Ltd., under date of April 11, summarizes the report of Philip Argall, consulting engineer to the company, announcing the completion of the new mill, and its satisfactory operation. The mill has a capacity of about 300 tons per day, and cost approximately $230,000. The ore on the dump, aggregating 600,000 tons, will be treated, in addition to the regular output of the mine. Regarding the proposed introduction of the caving system of mining, Mr. Argall says, "it will be necessary to take one level at a time and begin work at the farthest point from the main shaft, that is, the northern part of the property, starting the first 'cave' near the property line, preferably on the first level. When this cave is exhausted of profitable ore, another cave can be started nearer the shaft, and two or more can be operated simultaneously on separate veins. The object in each case will be similar, namely, to begin caving at the farthest point from the main shaft and gradually work back to the limits of pay-ore, extracting all the ore possible by drawing the 'caves' and leaving the ground and level behind completely caved and exhausted of pay-ore. When No. 1 level is so worked, caved, and abandoned, No. 2 can be taken up and treated in a similar way, and so with the deeper levels. If the main 'cave' on No. 5 level were first drawn, the 'cave' would soon pass into the hanging wall of the veins, and bring down barren country, as well as destroy completely the superincumbent levels. Furthermore, by caving the upper levels first, the lower levels as opened can be worked under lease, while the caving system is in full swing. The lessees can mine all the high-grade streak on the lower levels, but they must properly timber and secure the ground opened."

SALT LAKE, UTAH.

Sevier to be Sold at Auction.—Utah Apex Contract.—Ohio Copper.—Bingham Central Railway Bond Issue.—Incorporation of Bingham Mines Company.

The Sevier Consolidated properties in Piute county have been ordered sold at a receiver's sale to satisfy obligations approximating $187,500. The company was promoted by an Eastern syndicate headed by Seymour W. Tulloch of Washington, D. C., and expended nearly $900,000 in the purchase of mineral lands, mine, mill, and power equipment; but made the very serious mistake of not employing the services of competent mining engineers. The Sevier mine is regarded as being one of the best gold propositions in Utah, but has been handicapped by the lack of experienced talent.

The Utah Apex Mining Co. has let a contract to extend the Parvenue adit in Bingham, which will open the ore-bodies from 800 to 1000 ft. below the present workings. The present length of the adit is 2600 ft. and is to be continued as far again.

Development work in the Ohio Copper mine in Bingham has continued as usual, and the Mascotte adit, which is to become the avenue through which ores will be brought to the surface in the future, has been completed almost to the point where a raise is to be made to connect with the main shaft. The adit has been widened in places and double-tracked to permit the passage to and fro of ore trains which are to be propelled by electric power. Ohio Copper is one of the big mines of Bingham, but it has been held back on account of the financial entanglements of F. Augustus Heinze. It is believed, however, that Mr. Heinze is emerging from his difficulty, and that his plan to finance the Ohio, and build a railroad and smelter will be carried out. Evidence of this is furnished by the filing of a mortgage in the Recorder's office of Salt Lake county on the 25th in favor of the Metropolitan Trust Co. of New York for $3,000,000 from the Bingham Central Railway Co., organized prior to the financial upheaval in the latter part of last year. The railroad company gives as security for the above amount 6% 40-year gold bonds, as a first mortgage on its property in Salt Lake county redeemable in 1912, at the option of the company, at 105%. The purpose of the issue is for

Utah.

the construction, acquisition, and equipment of its line from Salt Lake City to Bingham, together with its branches and extensions, and for the payment of debts contracted and to be contracted in such construction, and in acquisition of other properties. For constructing that portion of the road in the Bingham district, and for tunneling through and under the properties of the Bingham Consolidated Mining & Smelting, the Ohio Copper, and the Fortuna Mining companies, the road is bonded for $1,000,000, or $250,000 per mile. For regular track-laying and other construction outside the Bingham district, $900,000 is set aside. The sum of $250,000 is to be used for additional equipment, and $500,000 may be used for securing additional trackage and extensions. Mr. Heinze's scheme has been to connect Salt Lake City with Bingham by an electrically operated road, with branches to the site of the proposed smelter west of Garfield, on the south end of the Great Salt Lake. The railroad is to enter the heart of the Bingham camp through the Mascotte adit.

Advices from the East indicate that the proposition to reorganize the Bingham Consolidated Mining & Smelting Co., under the name of the Bingham Mines Co., will be carried out as planned. Holders of more than 70,000 shares of stock have deposited their certificates with the Federal

Trust Co. of Boston, and the remaining shareholders have until April 30 to deposit their stock.

Ore shipments from the Park City district last week amounted to 691 tons, the contributing mines and amounts being: Daly Judge, 339; Silver King Coalition, 352 tons; while the shipments from Tintic amounted to 51 carloads, as follows: Bullion Beck, 2; Centennial Eureka, 44; Eureka Hill, 1; May Day, 2; Yankee Con., 2. The May Day resumed operations during the week, having been out of commission since about Jan. 1. The Grand Central and a number of other mines of the district will resume within two weeks, and will ship to the new Tintic smelter, which will go into commission in June. The ore-purchasing department, however, opens for business May 15. Announcement has been made that the United States Smelting, Refining, & Mining Co. will begin ore purchases about June 15.

BUTTE, MONTANA.

April Production of Copper.—Independent Smelter for Montana Ores.—Plant Acquired at Ponderay, Idaho.—Rich Ore-Find at Buxton.—Barnes-King.

The mines of the Butte district produced in April about 21,530,250 lb. copper, an increase over the March production of 3,403,000 lb. It is probable that May will witness an output of 27,000,000 lb. or more. The various companies contributed to the April total as follows:

Companies.	Ore. Tons.	Copper. Lb.
Boston & Montana	93,000	6,510,000
Anaconda	84,000	5,712,000
Butte & Boston	9,750	633,750
Washoe	9,900	693,000
Parrot	4,500	337,500
Trenton	6,000	366,000
North Butte	37,500	3,750,000
Butte Coalition	24,000	1,968,000
Original	12,000	1,080,000
Miscellaneous	6,000	480,000
Totals	286,650	21,530,250

The following figures show the daily ore tonnage, yield of copper per ton, and the daily average copper output:

Companies.	Tons.	Per ton. Lb.	Production. Lb.
Boston & Montana	3,100	70	217,000
Anaconda	2,800	68	190,400
Butte & Boston	325	65	21,125
Washoe	330	70	23,100
Parrot	150	75	11,250
Trenton	200	61	12,200
North Butte	1,250	100	125,000
Butte Coalition	800	82	65,600
Original	400	90	36,000
Miscellaneous	200	80	16,000
Totals	9,555		286,650

The Montana Mine Owners' Association, which was organized several months ago to furnish smelting facilities for its members independent of the American Smelting & Refining Co., has secured control of the smelter of the Idaho Smelting & Refining Co., situated at Ponderay, Idaho, on Lake Pend d'Oreille, and will increase the capacity of the plant from 250 tons to 1000 tons per day, giving employment to about 300 men. It is proposed to spend $100,000 on the improvements, and the plant will be equipped for treating copper, a refinery being added. The name of the operating company is to be changed to the Montana & Idaho Smelting Co. The smelter was built six years ago, but because of the opposition of the smelter trust, it is alleged, it has been prevented from achieving success. The Montana association has a five-year option on the plant, the price increasing as payment is deferred. If the option is taken up the first year it will cost $1,050,000, but in the fifth year it will have increased to $2,100,000. Immediate voting control of 55% of the stock is secured by the association, and the plant is to be operated on a basis of 15% net profit to the stockholders on all the ore treated. The smelter has connections with three railroads, and its location is said to be ideal.

An important discovery is reported from a new district 10 miles south of Butte in the Summit mountains, about two miles from the station of Buxton, on the Oregon Short Line railway. A rancher named Erick Rehen has been doing assessment work on some claims for 18 years, but never knew the value of the ground. Three months ago Peter Lackner, a young miner from the Lake Superior country, worked for the old man a week and then bought him out. There are 14 different leads in the ground. On one of them Rehen has been running a drift, which is 700 ft. long. The lead is from 60 to 100 ft. wide and the drift is on an orebody 3 to 4 ft. wide which assays from 3 to 4% copper, 20 to 25% lead, 20 to 30 oz. silver per ton, and 50c. to $4 in gold.

The March clean-up of the Barnes-King mine was $26,000. That for February was $19,000, and it is expected that the clean-up for April will be as good as that for March. The mine is now just about paying expenses.

While the Boston & Montana Co. was shipping its ore to the Washoe smelter at Anaconda that plant was run to its extreme limit and for a week or so has been turning out copper at the rate of about 20,000,000 lb. per month. It is reported that before it became necessary to treat Boston & Montana ore at the Washoe, on account of the wash-out on the Great Northern railroad between Butte and the Great Falls smelter, the Washoe smelter was turning out copper at the rate of 16,000,000 lb. per month, which was within 2,000,000 lb. of its highest record before the big slump in prices.

The Rarus mine of the Butte Coalition Co. is daily developing into a greater producer. On the 1700-ft. level a body of copper glance 2 to 4 ft. wide has been opened a distance of 600 ft. The glance assays 60% copper and there are 200,000 tons blocked out, giving 240,000,000 lb. of copper.

JOHANNESBURG, TRANSVAAL.

Lode Penetrated by City Deep Shaft.—Good Assay-Values at 3000 Feet.—Consolidation of Companies.—White Laborers to Work in Rand Mines.

The event of the week on the Rand was the striking of the reef in the City Deep shaft. For many days past, all eyes have been directed to this shaft, as it was known that the lode was not far away. Many people predicted that the assay-value of the lode when found in this deep-level mine would be poor, on account of the depth of nearly 3000 ft. On the evening of March 24 an 8-in. vein was found, assaying 155 dwt., while another sample taken from the opposite side of the shaft gave 89 dwt. across a width of 6 in. The average assay-value proves to be 11¼ dwt. across a 42-in. working-face. This result is highly satisfactory, and has put new hope into everyone. It is generally believed that this is the 'Main Reef' leader, the lower of the two lodes known to exist in this part of the country. Some weeks ago the shaft passed through the top or 'South Reef,' but the assays showed only a few pennyweights per ton, so that everyone was in fear that the lower vein would be equally poor. The satisfactory assays obtained has put a little life into the stock market, and more business has been transacted since the 'strike' than for weeks previous. On the strength of the good assay-values, the shares of the surrounding deep-level ground have stiffened considerably. Too much reliance should not be put on these two assay results, however, for a mine is not proved by two samples, but considering the fair permanency of conditions in the Rand there can be no doubt that the results are encouraging.

A huge amalgamation scheme was carried at the City Deep annual meeting. Five mines have now joined together to form one large company, the capital of the new company being £1,250,000, divided into shares of £1 each. This

enlarged company will have £450,000 available for the completion of the two shafts, the necessary development and equipment. The amount should suffice to enable the company to reach the producing stage with a minimum of 100 stamps and three tube-mills, capable of dealing with 22,000 tons per month. The plant is to be erected in such a manner as to permit additions when required. The Rand seems to have gone mad on the subject of amalgamation schemes. There can be no doubt that the formation of the deep-level claims into huge properties is sound from an economical point of view, but why many of the outcrop companies, which are on their last legs, should be amalgamated with their neighbors is not so obvious. It would seem a better policy on the whole to let these outcrop companies run their course. But amalgamation is in the air, and at nearly every annual meeting during the past few weeks, one expects to see some reference to consolidation.

After all the agitation on the question of the unemployed, the mines have offered to take on 800 white men from the first of April. Four hundred of these men are now doing 'unskilled' or rough labor in the streets of Johannesburg, so they will not go to the mines unaccustomed to hard work. One month after the first 400 get started, the mines will take on another 400 from the municipality. The main points in the terms of employment are that the white laborer is to do unskilled work above or below the surface, according to the instructions of the manager, his pay for work done being based on the present cost of such work at the mine in which he is employed. The white men are to be provided gratis with tents or other accommodations. The railways are also making every effort to aid the unemployed, and have decided to continue using white men as much as possible in place of Kaffirs. Mr. Wall, the chief engineer, states that from experience whites have proved better on earth-work and plate-laying, but not on maintenance of roads. This employment of whites in the Rand mines for rough labor is an important event. For the second time this experiment is to be tried. The first experiment, made just after the war, was a dismal failure. There were two reasons for the poor showing, namely, the wrong type of man was employed, and he was paid so much per day. In the present experiment these mistakes are to be rectified. The men who are going to the mines have been doing hard work for some time past, and their muscles are therefore in good condition. Then they are to be put on contract, and if a man does not work he will earn nothing.

CHICAGO.

Illinois Coal Mines Still Idle.—Agreement Between Miners and Operators Probable.—Dispute Over Law for Paying Shot-Firers.—Discrimination Against Non-Association Mines.

The coal operators and coal miners of Illinois have not yet succeeded in getting together and the mines are still idle. They are likely to continue to be until the middle of May at least and perhaps longer, but nobody cares much anyway, since there is plenty of coal in the market and prices have not gone up materially. There has been some stiffening of price, and many of the railways and large consumers will be scraping the bins before June, but at present they are optimistic. Meanwhile the negotiations, which began here last October drag on, and the situation changes from day to day. Just at present the difficulty seems to be within the labor organization, and a referendum has been ordered, which is to be taken at once. It looked this week as if the radicals were going to run away with things, which could only result in a bitterly contested strike. Now they seem to be losing their strength and the chances for an early agreement are better. The Toledo convention did not alter things so far as Illinois is concerned, as this State was not represented. Action at Toledo was not actually as conclusive as might be assumed, since it was merely permissive; work may be resumed in Pennsylvania, Ohio, and Indiana if the local differences are settled satisfactorily. In certain districts it is as yet by no means certain that they will be easily adjusted, though no one anticipates serious or general trouble. The Illinois operators stuck to their point that local differences must be settled before a general agreement might become possible.

For the first time in years the operators are better united than the miners. More than 90% of the State's production is now represented in the Association, and a defense fund has been provided. In the preliminary skirmishes the operators have won as much or more than they really expected, and probably a satisfactory agreement would have been concluded before this except that a majority of the miners' delegates came to the convention instructed by their locals to sign no agreement that did not include the payment of the shot-firers by the operators. This is the final bone of contention. On the one hand the miners point to the State law which says that the shot-firers "shall be employed by the company at its expense," and also to concessions by themselves on other points. On the other hand, the operators claim that aside from the payment of the shot-firers, their employment involves a heavy expense on the part of the company; that the law was enacted at the miners' request in the face of a specific contract that neither party would work for legislation materially affecting the terms of the existing contract; that the expense of the shot-firers, since they are required only in Illinois, is a differential against this State; and, finally, since the work was formerly done by the miners, they should either now pay for it or accept reduced pay. They hold that here the equities of the case warrant the practical nullification of the clause of the law regarding payment by assessing the cost back on the miners. The justice of this has been recognized heretofore by the miners, and by agreement they have furnished the money to pay the shot-firers. Unfortunately some operators, unfriendly to the law, have made the matter as burdensome as possible, or at least are charged with doing so, and the miners, to protect themselves, have given their delegates iron-clad instructions.

The second point of disagreement was with regard to the independent mines. Curiously enough the operators have been fighting for, and practically have won, a closed shop, though it is not polite to insist on that point. The status is this: Association mines employing union men are solemnly guaranteed the right to employ non-union men if they choose, but this is merely to protect against a charge of conspiracy, since the union men reserve the right not to work with non-union men. That is, an operator may employ non-union men if he wants to and can find them, but if he does so, no union man will work for him. Since all or nearly all the miners are in the union the result is that none but union men are employed in Association mines. However, there are a few mines which do not belong to the Association, and which have had separate contracts with the union. The power to start these mines up broke the last strike and defeated the operators, and the threat of making individual contracts has been the biggest club the union has held over the Association. Now the latter has turned and requires either that no union men work in a non-association mine, or else threatens to make no contract at all. By very adroit work they carried their point, and the miners have now shut down all the non-association mines which sell coal. A few, mining simply for the use of the owners (Illinois Zinc Co., etc.), are not affected. Of course too, Mr. Leiter's Zeigler mines, having been run for some years with non-union labor, are not affected.

The conservative element in the union, headed by District President J. H. Walker and National Secretary W. D. Ryan, seem disposed to make an agreement with the operators along satisfactory lines. The outcome of the referendum will be looked forward to with great interest. The fact that so bitter and long-continued a contest can arise where there is no dispute as to wages, hours, or recognition of the union, illustrates the complexity of modern organization, as does also the curious spectacle of the operators, apparently with substantial justification, working for what is practically a closed shop and an evasion of a cost assessed by State law. Evidently at the present time the simple rules of political economy must be greatly modified by the facts as they are.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Garnet is used for abrasive purposes, and is mined in the Adirondack region. The domestic production, which is increasing, amounts to 5500 tons, worth $33 per short ton.

Resuing is a method of mining small veins, in which the country rock adjoining the ore is first broken, and the clean ore broken down afterward. It is an economic method for many high-grade narrow veins.

Maltha is a fluid tar found near Carpinteria, on the shore of southern California. Here a bed of Quaternary beach sand, 20 to 30 ft. thick, is impregnated with liquid bitumen, which forms about 20% of the whole. A layer of richer bituminous shale underlies the sand and is the source of the tar.

A volcanic sill is a variety of lava dike which has been forced horizontally between beds of previous lava-flows, or between stratified rocks following the bedding-planes, or between the tuff and underlying rocks around a volcanic vent. Sills are a phenomenon most abundant in volcanic cones. When the amount of lava intruded in a horizontal position is great enough to float up the overlying rock and form a large mass with a more or less dome-shaped top, it is called a laccolith.

The earth temperature increases at an average rate of 1°F with every 50 to 60 ft. of depth below the zone of invariable temperature (the isogeotherm), which is found at depths, varying with the latitude, from 3 ft. at the equator to 60 ft. in arctic countries. But this rate of increase is not uniform. There are hot and cool spots in the upper rocks of the earth, the temperature in certain regions rising 1° with every 30 ft., and in others, as in the Michigan copper district, increasing at the slow rate of 1° for about each 212 ft. of additional depth. These differences have not been satisfactorily explained, but lower heat-conductivity is supposed to cause the cool spots.

Machine drills are widely used in Western Australia. For shaft-sinking and development work, the heavy ⅝-in. machine is in favor. For stoping, the smaller sizes, 3¼ in. and 2½ in., are used, and where the conditions for work and the hardness of the rock are favorable, the 2-in. machine is employed. The maintenance of a machine in constant work, for renewals of working parts and general repairs, is estimated to average about £6 per month during a life of about 18 months. Hand hammer drills are only used for cutting niches and breaking up large masses in the stopes.

Storage of lime for use in the cyanide process should be under conditions to prevent exposure to sources of excessive carbonic acid, which is apt to be plentiful in the vicinity of many mills, especially when steam-power is generated. Moreover, the amount of carbonic acid produced in the damp places under floors, where much organic matter usually accumulates, is often large. The lime is, of course, inert for the purpose of neutralizing acidity when it has become converted back into the form of the carbonate. Lime may be preserved without carbonatization in tanks after slaking better than in the form of 'quick lime' in lump.

Dynamite should be detonated with a strong cap, in order to develop higher efficiency in the explosive. There is a great increase in power obtained by using a 5-X instead of a 3-X cap. But great improvement in efficiency can be obtained by carefully placing the cap in the end of the primer so that the bottom of the cap shall be in contact with the powder, and not with an open space beneath it. The existence of such a minute air-space seems insigificant, but experiments have demonstrated that it does act as an air-cushion, materially lessening the force of the shock delivered by the explosion of the cap, and the force of the detonation of the powder always bears a direct relation to the initial impact.

Bauxite is a hydrous oxide of aluminum (formula $Al_2O(OH)_4$), occurring in masses accompanying clay or kaolin, and has been formed as an alteration product from other aluminous minerals. It is usually pale yellow or pale brown in color, of an oölitic or pisolitic structure, very soft, and of low specific gravity. The principal American deposits are in Georgia, Alabama, and Arkansas. It has been discovered on the upper Gila river near Silver City, N. M., and in a few localities in southern California. The basic patents under which aluminum is at present manufactured will expire in about a year, when the industry is expected to expand rapidly under the stimulus of open competition. Deposits of bauxite will consequently be in demand.

A make-shift concentrator that will yield good results is the old Gilpin county bumping-table. In its simplest form it consists of a plane surface inclined to about 4° from the horizontal, with flanged sides. The table is made of wood, covered with oilcloth, and is carried on four vertical spring-supports. A cam and tappet underneath impart a reciprocating motion, the amount of the throw being adjustable. The table is moved by the cam in the direction of the downward incline. When released by the cam the spring-supports throw the table against a heavy stop-block, jarring the concentrate upward toward the head-discharge. The pulp-feed is near the head of the incline, and a fresh-water feed is arranged across the width of the table between the pulp-feed and the upper discharge-lip. The old simple canvas-table is also useful with slime, but is of little avail in the concentration of moderately coarse sands. Hand-jigs are used extensively by the small operators in the zinc-lead district of Missouri, and would be valuable for preliminary work elsewhere when the heavy minerals in the ore occurred in relatively coarse particles.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Psychology of Mining Booms.

The Editor:

Sir—J. H. Curle's honest articles in your columns are always read by me with profit. He has something to say and says it briefly and clearly. The criticism of Mr. Claude Sachs reads like many a prospectus. He seems to voice the spirit of the boom-booster, while Mr. Curle is spokesman for the conservative miner. Mr. Sachs says "when results (proof of richness) from one or two mines in a new district are obtained, those to whom the opportunity is given would be perfect ninnies were they to fail to grasp the chance to acquire ownership in as much of the territory in the district as possible even though the cost might be out of all proportion to visible values." If he said "out of proportion to the extent of several times visible values" his remarks would be endorsed by many conservative engineers, perhaps even Mr. Curle. He also says that under similar conditions "excitement, speculation, and advances in prices far beyond visible or provable values is warranted. The district where one good mine is proved is the best place to find another." I think he will hardly be contradicted on that, either. The question between the two gentlemen seems to me to be in the character of the men who are in the booms and their ability to tell a mine, its prospects, and probable profits. As we all know the chief sufferers in booms are small 'investors,' far from the scenes of activity. "Mining can be a silly speculation or a sane gamble but never an investment." That covers the whole ground. Mr. Curle speculates himself, so do many miners, but he probably does it sanely. The public rarely can, especially in boom times. The evil deprecated by Mr. Curle is the discredit that falls on mining as an industry because of the inability and dishonesty of those who, during booms, advise the investor. As he says, it requires rare courage to hold back in such times.

CONSERVADOR.

San Francisco, April 4.

Variations in Mining Costs.

The Editor:

Sir—I have read with interest the article by J. R. Finlay in your issue of January 4, 1908, regarding 'Variations in Mining Costs.' This is supplemented in your leading columns by some illuminating remarks which are distinctly germane to the subject. Most engineers in the course of their careers have encountered some hard problems relative to cost, either in reporting upon or in the management of mines. Perhaps in the latter instance, where the subject is felt most keenly, is where a former superintendent may have whittled down costs by lavishly charging to 'development' all sorts and descriptions of general costs, the remainder being reported as the 'working costs.' The 'stumbling-block' and 'rock of offense' seem to be in the development account, as Mr. Finlay points out. What is development? Is it not equivalent to mine improvement? In other words, does it not increase the value of the mine through equipment or facilities of operation, and is it not distinctly an asset? Is not this what we invariably find in actual practice? I have in mind an instance where development was charged with an undue proportion of general costs, both above and below ground. Such charges included maintenance of buildings, traveling expenses, and plant maintenance, while underground mine-maintenance and pumping were included, the consequence being that the monthly charge for development was swollen beyond recognition, being actually doubled in cases, while stoping-costs had the appearance of having taken a course for obesity. At times the monthly cost for development was in excess of that for stoping, and this when stoping a wide lode under fairly normal conditions. The development costs were returned as so much per foot, while those for stoping were based on the ton unit. The consequence was that with a change of the management, when both development and stoping were put on the same tonnage basis and general charges were shown separately on the cost-sheet, the reported costs were so discordant with those formerly given as to seem detrimental to the new management. This is one extreme. There are instances in the Western States where no development account is carried at all. The managers, who in this case are also often the owners, argue that if the monthly receipts do not meet expenditures, the sooner they know this the better, and they will quit. Where costs are prepared by managers or consulting engineers for their directors, doubtless a development account will be esteemed necessary as tending to balance expenditure and to regulate operations, performing the function of a fly-wheel to a compressor.

In all examples given of work upon similar classes of deposits, and under like conditions, there should be a definite proportion between the expenditures for development and stoping. While it is true that the costs themselves may not be comparable between the cases in different places, the ratio of expenditure may nevertheless be constant. This being so, irregularity in these items is a fit subject for investigation. For wide deposits the proportion given varies from 9 to 15%—certainly not to exceed 20%; and yet we find costs returned under these conditions where the charge to development is even in excess of that for stoping under fairly normal conditions. Such stoping-costs are then established as a precedent, whereas, in fact, the working costs may be, without depreciation or other charges, from 50% to several times in excess of such quoted costs. Such a premise of working costs is sure to bring disillusion, if not dissolution, sooner or later. It would not be without gain were the profession to indulge in a little exchange of opinion upon the relation of the development account to the operating account in mine book-keeping.

The following questions are tentatively offered:

1. Is a development account a necessity in the practical working of metalliferous mines? If so, is

it essentially an operating charge or only partly so?

2. What is the best method for charging off such development account, and when?

3. What items constitute a fair charge to development, and in what proportion?

4. Are general charges, such as plant-maintenance, building-maintenance, hospital-account and fire-protection, chargeable in part to development, or wholly to mine-maintenance underground?

5. What general accounts are chargeable, and in what proportion?

6. Shall such mining charges as pumping be charged in part to development,

(a) When such development is in no way dependent on pumping?

(b) When pumping is neeessary, as in shaft-sinking, or developing a lower level?

7. Is hoisting chargeable to development for waste hoisted, unless such can be utilized as filling below? When ore is broken in development, if charged to hoisting, what credit should development receive? In either case, would it be advisable not to charge hoisting?

8. When drifts are driven in ore, and raises and winzes are made in blocking out ground, or when cuts are made in ores, are not these fair charges against stoping?

9. In the case of rock-drifts or work that will be serviceable for a number of years, is not such a fair charge against development?

10. In the case of sinking working shafts between levels, these are a fair charge to development account. When a new shaft, entailing considerable outlay, is undertaken, this may be a fair charge to capital account, and is not considered as a revenue account, unless operations are so comprehensive as not to become in any way disorganized thereby.

11. How is it proposed to deal with depreciation charges? Shall we assume a life of from 5 to 10 years and charge per ton of ore what is thus annually written off?

12. As to amortization charges, how is it possible to recognize this in the working costs at the mine? Is not such a matter one for the directors or for the shareholders?

13. Regarding the writing off of depreciation charges, being an important item, often running into a considerable figure, thus largely governing the real profit or loss, is it advisable that this should be controlled by the manager at the mine, rather than by directors at a distance?

It appears to me that under the heading of development should be charged off the underground expenses that cannot be directly or indirectly considered as an expense in the breaking and extracting of ore. Development referring to new work is essentially an asset in the equipment of the mine. An example may be more explicit. A rock-drift, intended to facilitate the working of orebodies for a period of years would be a correct charge against development. Development, finally, is as much a working expense as stoping. The feature, however, that it seems essential to keep before one is that no matter how accounts may be sub-divided, ultimately there is but one source of revenue to meet such expenditure, and that is the value of the ore extracted. All expense, sooner or later, is chargeable to the ore account. Income and expenditure must balance, otherwise the undertaking is being run at a loss, no matter what the balance-sheets may say. The total mining costs include every expenditure, no matter under what subdivision such may fall, whether mining, development, general costs, or amortization.

Such total expenditure divided by the total tonnage gives a cost per ton that is comparable the world over. Any item omitted or curtailed renders the reported cost unreliable and useless for purposes of comparison.

TRIBUTER.

Foothill Copper Belt of the Sierra Nevada.

The Editor:

Sir—In your issue of March 21, under the above heading, John A. Reid draws an erroneous conclusion in stating with reference to the entire foothill belt that "the ore consists essentially of original sulphides, little secondary material having been formed." This conclusion might be allowed to pass unchallenged were it not that its effect may be pernicious as tending to give undue confidence in the belt as a whole and to discredit the work of others who have examined particular mines and describe the commercial ores as due to secondary enrichment in the upper portion of the sulphide zone and hence probably rather limited in depth. Mr. Reid gives detailed descriptions of two properties, the Copperopolis and Pocahontas, and I have no fault to find with his conclusion that their orebodies are chiefly original sulphides; but he is in error in the sweeping intimation that similar ores are the rule throughout the belt. The foothill copper belt is over 250 miles long, and contains hundreds of old mines and prospects. There is such great variety in the character of the ore deposits that no general rule can be applied. Every deposit must be considered separately and will be found to present some new feature.

In the spring of 1906 I followed the belt from Tulare to Amador county, visiting many of the principal properties, and although, through my notes having been destroyed in the San Francisco fire of that year, I cannot be specific, I remember that I gained the impression that in the portion of the belt southeast from Copperopolis the majority of the orebodies of commercial grade (leaving out of consideration the generally exhausted carbonate and oxide ores in the zone of oxidation) are typical examples of secondary enrichment in the upper portion of the sulphide zone. Bornite and chalcocite are important constituents. Many of the mines have not been carried deep enough to expose the primary sulphides, but in some important cases I believe this has been done. For instance, it is my impression that at the Green Mountain mine in Mariposa county and at the mine on the Daulton ranch in Madera county, the rich sulphides give place at a depth not exceeding 200 ft. to large bodies of low-grade cupriferous pyrrhotite, the primary ore. The Buchanan mine in Ma-

dera county was an important producer at one time, but the base of the enriched sulphide ore has not been reached.

I have made a more thorough study of three old mines on the belt southeast of Copperopolis. At the Victoria mine in Mariposa county there are, below the zone of oxidation (which is from 30 to 70 ft. deep), small lenses of sulphides which in places are nearly pure pyrite, and in others pyrite plus chalcopyrite and chalcocite. I regard this as the primary sulphide ore to which some copper has been added by the secondary enrichment process. The unaltered sulphide zone is not exposed. At the Cavan mine in Mariposa county, the zone of oxidation seems to extend to a depth of about 100 ft. The sulphide ore exposed down to a depth of 172 ft. from the surface has bornite as the chief copper mineral, although chalcopyrite appears in the lower part of a shaft 155 ft. deep. I believe the primary sulphide to have been chalcopyrite very sparingly distributed (along with a little pyrite) in narrow zones of schist and in little quartz masses in the schist. The decomposition of this schist hundreds of feet in depth caused the copper salts to travel downward, gradually concentrating into seams and kidneys of crushed rock which in course of time became quite rich. I never saw a more evident case of secondary enrichment than at the San José workings of this property, as the minerals are those typical of such ores and have been deposited by descending water following lines of weakness in the schist and brecciated quartz. At a mine in Tuolumne county which I recently visited, the zone of oxidation is about 90 ft. deep. Thence to the 350-ft. level, the deepest in the mine, the copper mineral is almost entirely chalcocite. A little chalcopyrite (the presumed primary sulphide) appears with the chalcocite in the deeper mine openings, but it is evident that the bottom of the zone of secondary enrichment has not been reached, unless, indeed, one entertains the revolutionary idea that some of the chalcocite is an original sulphide. Unusual porosity of the ore favored deep penetration by the enriching solutions.

These examples will show that while one man's experience may lead him to think that the workable orebodies of the foothill belt are prevailingly of primary sulphides, another man may gain the impression that the process of secondary enrichment has been necessary at most places on the belt to produce commercial ore. I anticipate that the final review of studies on the entire belt will show that southeast of Copperopolis there will be found comparatively little primary ore of commercial grade; that from Copperopolis northwest, the original sulphides will take a much more important part in the production (although there will in that region also be much secondary sulphide ore), and that the Copperopolis deposit is unlike any other on the belt. In the meantime I must protest against writers forming conclusions for the entire belt based upon a study of only one of the many types of deposit represented throughout this extremely interesting region.

Berkeley, April 3.

Drill Contest on the Rand.

The Editor:

Sir—In your issue of March 28 there appeared a letter on this subject writen by one who signs himself 'Mine Manager.' The gentleman appears to have overlooked the fact that 40% of the holes drilled in the South African stope-drill contest were upcast holes. He says: "The entire contest was based on drilling inclined holes in a perpendicular face." This is not true, for out of the whole four days which each drill had to run, not over an hour was spent by any competitor in drilling inclined holes in a vertical face. This is certainly a very small part of the four days, and furthermore the inclined holes in question were upcast and not downcast holes.

The conditions of the contest were fixed by a joint committee (of which the writer had the honor of being a member) consisting of mine managers, engineers, and drill-manufacturers. Every effort was made to make the conditions equally fair for every type of drill and at the same time to prove the relative drilling power of each type under the different mining conditions found in the numerous mines of the Rand. The entries included six drills of the percussive type, three of the hammer type with air feed, one hammer drill with a screw feed, and two of the Gordon type.

It was on just such upcast holes as 'Mine Manager' considers ideal that the winning drill, the Gordon, did more than double the work of any other competitor. Numerous rules were made in order that no question might arise as to the justice of the results, but the main points were as follows: All holes must be over 36 in. deep; all holes must bottom or finish large enough to take the standard sticks of explosive; all holes were to be drilled approximately as indicated by the judges before the work started.

Each day's work on the surface consisted in drilling for one hour in each of the test blocks, three hours being spent on downcast holes and one hour on flat and upcast holes. Underground one day was spent on drilling downcast holes in an overhand stope and one day in drilling upcast holes in an underhand stope.

Cornish Pumps of New Design.

The Editor:

Sir—In your issue of January 18, 1908, there is a short description of a pumping plant installed for the Loddon Valley Gold Fields, Ltd., Australia, by E. P. Jones, the designer of this plant. It would be interesting if Mr. Jones would furnish a few additional particulars. The information wanted pertains chiefly to the air-receiver, and to the efficiency of the plant. As the pump is operated by an engine, presumably of the crank and fly-wheel type, the use of an air-receiver and alleviator becomes more necessary than with a direct-operated pump, as in the case of a beam-engine, by which the larger sizes of Cornish pumps are usually operated. The reason for this is evident on account of the velocity of discharge varying throughout the stroke, being 1.57 times the mean

velocity at mid-stroke. This objectionable feature causes shock, which would be detrimental to the pit-work and especially so to the large discharge-valve of a type such as the compound-clack. As the tendency of water under pressure is to absorb air, for which an air-charging apparatus has apparently been provided, what is the idea of the connection to the rising-main with the air-receiver? Is it to control the air-supply, provided too much should be supplied by the automatic air-supplier? What would be the effect without such a by-pass?

I have had experience with a 26-in. plunger pump, operated by a beam-engine and raising water about 250 ft. vertically, where such compound clack-valves were used. Working at about 8 strokes per minute, the water-hammer was so great as to fracture the door, and crack the valve-piece, both in this instance being made of gun-metal. An air-chamber was provided at a branch at the top of the shallow shaft. Unfortunately, when erecting, this piece met with an accident, and a bend was substituted. A remedy in this instance was effected by discarding the clacks and substituting four-beat valves, which, in the writer's opinion, are preferable where exceedingly large valves are required. Water-works engines invariably have large air-receivers, to facilitate the forcing of a great volume of water through long mains with absence of shock. These engines, moreover, represent the highest mechanical efficiency and 'duty' of which the Cornish type is capable, though it is not comparable with the vertical triple-expansion, condensing, three-crank, differential-plunger engine that attains a duty of 160 million foot-pounds of work per 1000 pounds of steam used by the engine, possibly representing the highest economy of the present day.

The next point is in respect of the efficiency of the plant. Mr. Jones remarks, "A Cornish pump-plant of large capacity should give a total combined efficiency of about 80%: this being taken from the throttle valve of the engine to the water delivery." Now, what does Mr. Jones mean precisely by this statement? At first, as the throttle-valve was mentioned, it suggested to me that the steam consumption was taken as the basis of efficiency with regard to the water lifted; or, in other words, the 'duty' of the plant. What is probably meant by giving 80% is the 'mechanical efficiency,' which is the actual or net horse-power of the machine divided by its indicated horse-power, and the quotient multiplied by 100. On this basis we find that small direct-acting steam pumps have an efficiency of about 50%, increasing with the size of the pump to about 80%. Large vertical municipal pumping engines are quoted as having shown an efficiency as high as 96%, and horizontal medium-size crank and fly-wheel pumps an efficiency as high as 90%. The 'duty' of such pumps, on the other hand, based on a consumption of 1000 lb. steam used, is about fifteen million foot-pounds for small direct-acting pumps. Compound direct-acting pumps of five million gallons capacity per 24 hr. should give a duty of about fifty million foot-pounds. Large municipal pumping engines of twenty million gallons per 24 hr. have given a duty of one hundred and sixty million foot-pounds. Such records are only attainable under the best conditions. Perhaps Mr. Jones will be able to give the 'duty' of the plant designed by him, based on the standard steam consumption, or better still, in British thermal units.

Although the action of beam-engines is more constant in velocity, and therefore more favorable for pit-work, would Mr. Jones suggest the advisability of equipping all 'lifts' with suitable air-receivers? And, as the economy of the crank and fly-wheel type is manifestly more economical than the beam, as it admits of more expansions, which in the beam-engine is governed entirely by a consideration for the pump-rods, would Mr. Jones suggest the advisability of adopting the crank-engine in the larger sizes of pit-work, for which the beam-engine is invariably adopted, at least, in deep mining?

The efficiency allowed the electrically driven turbine pump-plant, comprising steam-generating apparatus, is given at 45% for the total combined efficiency. Are we here dealing with 'mechanical efficiency,' or the ratio of work from steam and water ends, otherwise the 'duty'? While up to 65% may be allowed for large rotary pumps, I have no reliable data as to the mechanical efficiency of the modern multi-stage turbine. Possibly someone with the requisite data will be good enough to state what may be expected in the way of 'mechanical efficiency' and 'duty' for a steam-electric turbine pump-plant. Electrically operated turbine pump plants are becoming common nowadays, and in some instances are well spoken of. Doubtless, with regard to economy it is largely a matter of local conditions, and is favored by hydro-electric generation in places where a horse-power may cost $50 per year or less.

Were five million gallons per 24 hr. to be raised 1500 ft. vertically at sea-level, where electric or steam power can be generated at $100 per horse-power year, it is inconceivable that the Cornish pump can successfully compete with more modern steam or electric pumping plants.

In this connection I recall the instance at the Difficultad shaft of the Real del Monte company, Pachuca, Mexico, where a large compound-cylinder beam-engine, of German design, with a rated capacity of five million gallons per 24 hr., pumping through a wrought iron column 3 ft. in diameter, has been successfully supplanted by a four-stage turbine pump, driven by a 750-hp. alternator at 900 rev. per min., pumping through a 16-in. column 2400 gal. per min., against a head of 730 ft. The district, however, favors the use of electrical power.

I am aware that Mr. Jones is not posing as the champion of the Cornish pump. In fact, from his concluding remarks, I imagine that he considers it a somewhat cumbersome and expensive equipment, but capable of good work and fair efficiency, under favorable circumstances, though easily surpassed in both by more modern plants.

OLD TIMER.

Redruth, March 4, 1908.

[We invite further comment from professional men on this interesting subject. EDITOR.]

CYANIDATION OF SILVER ORE IN MEXICO.—II

By W. A. Caldecott.

*The reactions involved in the dissolving of silver from its ores admittedly still require much study before they are clearly understood. The following discussion is rendered imperfect on account of the non-arrival of a parcel of Mexican silver ore, upon which it was intended to carry out tests to develop and confirm the tentative conclusions arrived at from an examination of the properties of artificially prepared silver sulphide. The study is instructive, as apart from its direct interest, it has a bearing upon the treatment of gold ores containing sulphides which dissolve in cyanide solution. It is probable that since the mineral silver sulphide is coarser and more compact than the artificially prepared compound its dissolving in cyanide solution is slower, thus allowing more time for secondary reactions to proceed.

The primary reaction in the dissolving of silver sulphide from its ores may be taken as:

$$Ag_2S + 4NaCy = 2NaAgCy_2 + Na_2S \qquad (1)$$

Another suggested equation is:

$$Ag_2S + 6KCy + H_2O = 2K_2AgCy_3 + KOH + KSH$$

When, however, a certain amount of silver has been dissolved by the above reaction an equilibrium is established and solution ceases. How far the reaction has proceeded before this equilibrium is attained, depends on the amount of soluble sulphide in solution, whether derived from silver sulphide or other sources, and the amount of free cyanide present. Heat also increases the solubility of Ag_2S in cyanide solution. The following table shows the results obtained from a series of argentiferous sodium cyanide solutions of the strengths stated, 100 c.c. of each of which was titrated with 0.1% sodium sulphide solution until a brownish coloration was just produced. A reduction of 0.05 c.c. was made from the reading, so as to give the amount of sodium sulphide that could be added without reacting with the silver present.

Table A.

Free cyanide (as KCy) %	Silver present mg. per litre.	Na_2S required mg. per litre.	Equiv. sol. Ag present as Ag_2S mg. per litre.
0.50	490	5.3	14.7
0.40	392	4.4	12.2
0.30	294	3.1	8.6
0.20	196	2.0	5.5
0.10	98	1.0	2.8
0.05	49	0.7	1.9

An inspection of the foregoing table, in which milligrams per litre may be read as grams per metric ton, shows that the amount of silver sulphide capable of being dissolved as the soluble double alkaline cyanide is approximately proportionate to the amount of free cyanide present, but even with 0.5% solution the quantity of dissolved silver is less than 0.5 oz. per 2000-lb. ton. Further, it is obvious that the introduction, through the presence of a free alkali, of soluble sulphides into an argentiferous cyanide solution from any mineral or other source will result in the precipitation of silver already dissolved. The fact that dissolved silver and other than very small amounts of sodium sulphide cannot exist simultaneously in the same solution serves to explain why working solutions do not show more than traces of the latter when sulphide ores are being treated. With solutions low in silver it is difficult to filter off the very finely divided suspension or colored colloidal precipitate formed on addition of sodium sulphide solution to sodium-argento cyanide solution.

The explanation of how in practice many ounces per ton of silver existing as sulphide in the ore can be dissolved can be explained by the occurrence of secondary reactions, and to these attention may now be directed. They show the conversion of soluble alkaline sulphide first formed into other compounds which do not preclude the further solution of silver, and thus the primary reaction appears to be merely a transition state in the sequence of reactions. No doubt, various of these secondary reactions proceed simultaneously, and the formation of the resultant products indicated has been experimentally proved by their detection in the solution.

The following are the secondary reactions referred to:

$$(a)\quad \begin{cases} 2Na_2S + 2O_2 = Na_2S_2O_3 + Na_2O & (2) \\ Na_2S_2O_3 + Na_2O + 2O_2 = 2Na_2SO_4 & (3)\dagger \end{cases}$$

$$(b)\quad Na_2S + NaCy + O = NaCyS + Na_2O \qquad (4)$$

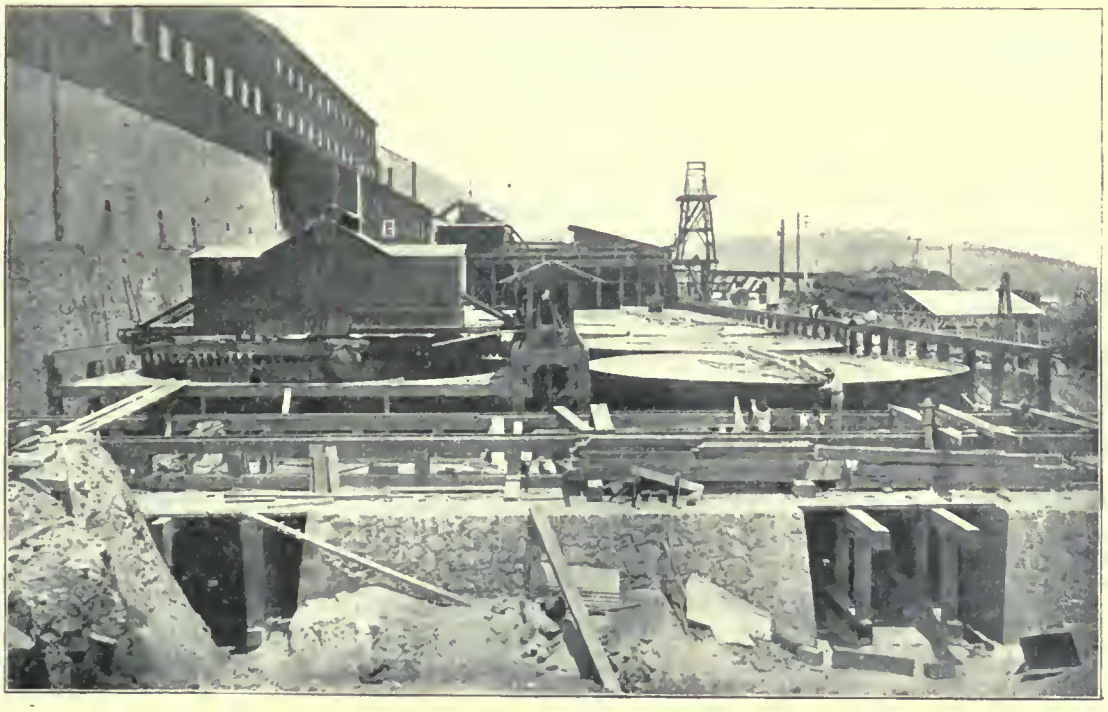
$$(c)\quad \begin{cases} Na_2S + PbO = PbS + Na_2O & (5) \\ PbS + NaCy + O = NaCyS + PbO & (6) \end{cases}$$

The foregoing reactions, when carried to completeness, all involve absorption of oxygen, whereby the utility of aeration may be accounted for, apart from its accelerating the solution of any metallic silver or gold present in an ore under treatment. Reaction (*a*) apparently proceeds a good deal more rapidly than (*b*), and since it does not involve destruction of cyanide, and indeed is not required to proceed further than the first stage, resulting in the production of sodium thiosulphate (itself a silver solvent), this may be considered the most desirable result of aeration. Reaction (*c*) with lead present as suspended hydrate or soluble alkaline plumbite has the advantage of instantly converting the soluble into insoluble sulphide, and also the reaction being cyclical, given sufficient oxygen, a limited quantity of lead salt serves to remove an indefinite amount of soluble sulphide, but this last result is only attained at the expense of free cyanide being converted into useless sulphocyanide. If bad peroxide could be employed as soluble alkaline plumbate, a double quantity of soluble sulphide should be removed as sulphocyanide and insoluble sulphide.

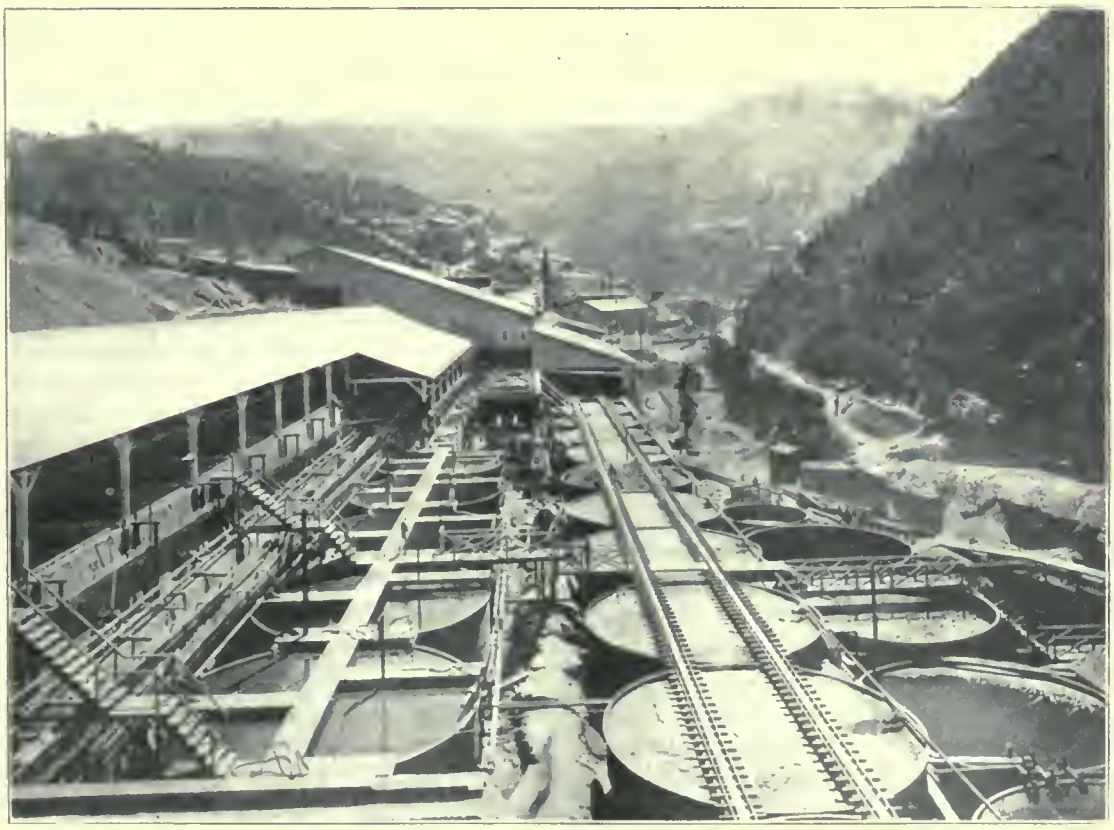
To ascertain whether, in addition to the foregoing reactions, involving absorption of dissolved oxygen, sodium sulphide could be oxidized at the expense of oxygen combined in water, an aqueous 2.97% solution of sodium sulphide was allowed to stand for five days in a filled and closed vessel. At the end of this time no loss of strength could be detected, nor were thiosulphates, nor sulphates present, whereas a parallel test in a closed flask only one-eleventh filled showed on opening reduction of internal pressure, a reduction of strength to 2.85%, and the presence of sulphate in solution.

*Abstracted from *The Journal* of the Chemical, Metallurgical & Mining Society of South Africa, January, 1908.

†See Watts' Dictionary of Chemistry, New Edition, p. 483, Vol. IV.



Cyanide Plant of the El Oro Mining & Railway Co. at El Oro. Blaisdell Excavator in the Left Foreground.



New Cyanide Mill of the Dos Estrellas Mining Co. at El Oro.

Since in Mexican practice little lead seems to be deposited from solutions entering the zinc-boxes it does not appear as if the cycle (*c*) were usually completed, but from a scientific standpoint its possibility is of interest. Apart from any re-formation of PbO, nearly as much lead as there had been silver present as sulphide is required to carry equation (5) to completion.

While the relatively weak solutions included in Table A dissolve silver sulphide in proportion to the total amount of cyanide present, yet with concentrated solutions this does not hold, as cited by Comey. A strong cyanide solution saturated with silver sulphide will yield a deposit of this salt on dilution with water, and such a precipitate can be successively formed and dissolved by alternate additions of water and concentrated cyanide solution.

A study of the molecular weights involved in equation (1) shows that the silver requires nearly its own weight of sodium cyanide to dissolve it, so that the consumption from this cause alone with 500 gm. silver ore would be nearly a pound of sodium cyanide a ton. This feature, as one of the sources of high cyanide consumption experienced with silver ore, renders the field for cyanide regeneration processes a good deal more promising than with banket gold ore, where the total cyanide consumption need not necessarily exceed a very few ounces per ton. Apart from reactions taking place in the presence of lead salts, the absorption of oxygen in reactions (*a*) and (*b*) is considerable; in fact, even in the stage of (2) it amounts to one-seventh of the weight of the silver dissolved. Hence, under these conditions, although oxygen does not play the direct part in dissolving the silver that it does in gold ore treatment, yet its importance in permitting solution to proceed, and the present necessity for the tedious process of repeated agitation and aeration, appear evident. On like grounds experiments by agitating silver sulphide and cyanide solution with the oxidizer barium dioxide, or with air under 100-lb. pressure showed considerable more silver dissolved in a given time than in the absence of either. To illustrate the fact that introduction of sodium sulphide does not cause precipitation of silver when sufficient dissolved lead is present, the following table is of interest, since from this it follows that the presence of dissolved lead allows solution of silver sulphide to proceed, as in equations (1), (5), and (6).

A solution of lead plumbite containing 1.95% PbO was prepared by dissolving precipitated lead hydrate in caustic soda solution. Six argentiferous sodium cyanide solutions, of the strengths stated were also prepared, and to each was added the stated amount of lead as plumbite. Then to each was added sufficient sodium sulphide in solution to combine with all the dissolved silver present. The flasks containing the solutions were then closed and agitated for an hour, after which the solutions were filtered and the precipitate assayed for silver. The results are as shown at the head of the next column.

The trivial amounts of silver in the precipitate show how effectual the presence of lead is in preventing precipitation of silver, and consequently in

TABLE B.

Free cyanide (as KCy) %	Silver present mg. per litre.	PbO added as plumbite mg. per litre.	Na_2S added mg. per litre.	Mg. silver precipitated per litre.
0.50	490	2,600	177	3.37
0.40	392	2,080	141	1.73
0.30	294	1,560	106	2.00
0.20	196	1,040	71	2.30
0.10	98	520	35	0.90
0.05	49	260	18	0.37

permitting the dissolving of silver sulphide to proceed in spite of the concurrent formation of soluble sulphide. To confirm this latter deduction, the first and last experiments of Table B were carried out again on similar lines, but in this instance the sulphide was added before the plumbite. Only trifling amounts of silver were found in the precipitate.

Mercury salts probably act in a similar way to lead salts in forming an insoluble sulphide, though they are but little used on account of their higher cost. Possibly also direct replacement of mercury in the double alkaline cyanide by silver takes place, as claimed by Keith and Hood. It is claimed that only mercury in the mercurous state assists in the dissolution of the silver, so that use of calomel should be preferable to that of mercuric chloride. To account for the dissolving of metallic silver and silver chloride, the following simple equations may serve:

$$Ag_2 + 4NaCy + O = 2NaAgCy_2 + Na_2O \quad (7)$$
$$AgCl + 2NaCy = NaAgCy_2 + NaCl \quad (8)$$

In order to determine how far results in practice are affected by chemical reactions, and how far by the mechanical factor of fineness of crushing of the silicious matrix, it may be of interest to recall a method of examining cyanide residues for encased values. In examining residues of silver ore, boiling in strong nitric acid might be employed, followed, after washing, by agitation with strong cyanide solution and barium dioxide. Boiling in aqua regia in the first instance might tend to produce insoluble silver chloride, whereas nitric acid would form soluble silver nitrate, and after its removal any exposed gold would be dissolved by cyanide as above, or aqua regia might then be used for the second stage.

In conclusion, I trust that this brief and imperfect account of some metallurgical conditions and problems in the largest silver producing country in the world will be considered as a timely variant from our ever present problems of gold ore treatment. If the publication of this paper should serve to elicit further information from those engaged in treating silver ores, or from those interested in the subject from its scientific aspect, the writer's object will have been attained.

I desire to express my indebtedness to A. McA. Johnston and F. W. Watson for carrying out at the Consolidated Goldfields laboratory the experimental work quoted in the paper.

Cryolite is only known to occur in commercial quantities at Ivigtut, in South Greenland. It is used for the manufacture of sodium salts, of special kinds of porcelain and glass, and as a solvent in the electrolytic aluminum process. Calcium fluoride is a by-product in the process of making sodium salts, and this is used as a flux in open-hearth steel furnaces.

STOCK COMPANIES AND COMPANY PROMOTION.

By Henry A. Butters.

*Webster gives the definition of stock company as: "An incorporated company the capital of which is represented by marketable shares having a certain equal par value." Accordingly, the shares relate to the capital of a company and are what is commonly called the stock. The capital of a company may be divided into common and preferred stock, the latter being of several varieties, bonds and debentures. These are all comprised under the generic term, securities, and bear no fixed relation to the actual cash capital. There may be stock without bonds or debentures, but there can be none of the latter without the former.

When a company is described as having one million dollars in capital stock, it means that it has a certain number of shares each having an equal, arbitrary, nominated, par value, the total of which is one million dollars; the par value of each share may be anything from one dollar up. In railway and industrial shares, par is usually one hundred dollars. Such a company may not have one dollar in cash, in fact, would not, until some of its securities had been converted into cash. Then it would have only as much cash as had been realized by such conversion, the amount bearing no fixed relation to the par value of the securities. One half, or five hundred thousand dollars, of the total million in stock, might have been sold for twenty-five thousand dollars, in which event, while the nominal capital of the company would be one million, its actual available cash would be twenty-five thousand dollars. The amount of the capital stock may be purely arbitrary, but should be proportional to the value of the undertaking or business to which it relates. Although companies are formed with the capital stock divided into a given number of shares, each having a nominated par value, in point of fact the organization would be just as effectual if a company should be formed having a given number of shares without any expressed value. If one owns ten shares in a company having one thousand shares, then one owns an integral part of the concern amounting to ten one-thousandths, or one per cent; and that is the essence of the relation of shares to capital. The fact that stock is usually expressed in terms of monetary value is because in theory there is supposed to be a fixed relation between the value of the stock and the undertaking it stands for; there is, however, often a departure from that theory in general practice.

Incorporation furnishes the best known method for enabling a number of individual units of capital to combine to form a large aggregate, the total of which would be more than individuals could command, or might wish to put into a single enterprise. It gives each individual interested a share or ownership which is definitely expressed, and on which he can deal with third parties independently of the other owners or stockholders, and enables the majority to manage the undertaking. Most of the objectionable features of the co-partnership are eliminated in a corporation. Its affairs are governed by a board of directors; and the death, or embarrassment of any individual member does not hamper its operation. To illustrate, suppose that a number of persons wished to contribute a certain sum for the purpose of establishing a fund for engaging in mining or any other business. They form a co-partnership, and so long as all live, and maintain integrity, everything may go satisfactorily. But suppose one of the co-partners should die; then his executor steps in, and the interests of the deceased come under the direction of the court. The situation thus created is fraught with unpleasant potentialities. The court may order the liquidation of the deceased partner's interest; he may appoint some disagreeable person to represent the interest; he may decide that a particular policy is not for the welfare of the heirs. The surviving members of the firm are thus likely to be subjected to serious annoyance, if not to actual losses. Then, too, if one of the partners speculates or gambles, or for any other reason becomes demoralized, it is in his power to incur obligations in the firm's name and use the proceeds for his own ends to such an extent as to involve the concern and often to cause its ruin. In the same case, if each contributes money and all form a corporation, then the individual interest is represented in shares of the capital stock, and the undesirable features of the co-partnership are entirely eliminated. The affairs of the company would be conducted by a board of directors, chosen by the majority of shares, each share having one vote; and in case of the death of any individual, neither executor nor court would have jurisdiction further than to control the voting power of the shares of the deceased member; and the corporation would continue its enterprise unhampered. If the deceased member had been a director or an official, the surviving members of the board would select his successor to serve until the next regular annual election.

The capital stock of a company always serves as a means of apportioning interest, but not always as a measure of value. For example, suppose a mine in which, let us say, there is a net value of ore reserves of $500,000. The mine is purchased on a basis of $^3/_4$ its net reserve, that ore reserve being arrived at in the following manner: We will suppose a million gross in sight. A working plant is required, to cost $250,000, and the cost of mining and reducing the ore would be $250,000. This would leave a net product of a half million, plus the plant, which, unless the ore continued in sufficient quantity to make its operation profitable, would become a negligible quantity and should not be taken into account. In order to go to the public for money, the basis of capitalization would be about as follows:

Price of mine - - - - -	$350,000
Plant - - - - - - - -	250,000
Working capital, cash - -	50,000
Total - - - - - -	$650,000

A fair capitalization of such a proposition would be one million two hundred thousand shares, out of

* A synopsis of two lectures delivered to the Seniors of the School of Mines, University of California. By courtesy of the author.

which there would be sold to the public one million shares at 65% of par, to produce $650,000. The promoter would take a commission of one hundred thousand dollars worth of stock for his own profit, and leave in the treasury the remaining one hundred thousand as a reserve, to be drawn upon for future needs. In such a case the promoter's one hundred thousand in stock would represent accurately the apportionment of his interest, but the term one hundred thousand dollars would not express accurately the value of his interest, because at the moment its value would be only its proportion of six hundred and fifty thousand dollars, the total amount of cash involved. If future operations, however, should disclose another extensive body of ore it might be worth much more than its par value of $100,000. And now just a little explanation as to why the capital has been estimated at a million, the selling price of stock at 65%, and the commission at $100,000. In dealing with commercial, industrial, railway, and kindred enterprises, there are usually tangible bases for computing not only legitimate earnings for, but also amortization of, all securities. In mining, the situation is generally the reverse, and this is the case in the illustration under discussion. There is an element of risk to be reckoned with, and the investor must have a larger margin for possible profit to compensate therefor. Accordingly, the shares are sold at 65 instead of at par; the inference being that if the ore should continue as expected beyond the visible supply, and other probable orebodies be encountered, the value of the stock would increase to par. Manifestly, as the stock is to be sold at 65, there must be a sufficient amount to realize the requirements at 65, and also to provide the two amounts of one hundred thousand each for the promoter and the surplus. All of which can be accomplished only by making the amount $1,200,000. The amount of commission, namely, one hundred thousand to the promoter, would be only a fair profit on such a transaction. He would be entitled to as much more as he could get. The surplus in treasury stock is safe because the mine being dealt with is on a paying basis with large orebodies exposed.

In the search for a good mine, many prospects will be brought to your attention. They may be acquired by original location, or offered by others in the field before you. While it is an axiom that "gold is where you find it," for the novice it is much the safer course to apply himself to geological formations exhibiting the known characteristics which denote the existence of orebodies. It may be taken for granted, therefore, that he will not waste time on any other prospect. Having acquired the prospect in a zone possessing the proper earmarks of mineralization, let us discuss the method of procedure to enlist capital. Always bear in mind that capital is greedy. It is likewise generally timid. Dealing with a capitalist is much like doing business with a lawyer. Your own lawyer draws up a contract as favorable to you as possible, and the other lawyer tries to make it unfavorable to you and favorable to his client's interests. The capitalist working out your proposition will only consider his own advantage in the matter, giving no thought to you. Therefore your own cut-and-dried proposition is likely to be better for *you*. His mind is thereby fixed upon your picture instead of leaving him to make one of his own. Again, a clear, well-defined, written proposition, properly presented, will often engage his attention when a verbal, general haphazard talk will not make the least impression. The capitalist is usually a man of affairs; and such men are usually busy, and have neither the time nor the inclination to do your thinking for you. Many men with good propositions fail of success because they do not make a good presentation. The initial presentation, then, is of prime importance. It should include a general description, giving geographical position, geological conditions, description of workings if any, and what they contain and reveal, all brief and concise. Also reasons for presuming that paying ore may be found, such as contiguity of profitable mines, reasons for analogy, and above all, actual value already proved, as well as physical advantages for practical mining and reduction, such as timber, water-power, and transportation. Following this would come a statement of the amount of money required, which should include a surplus beyond visible needs; then the basis of capitalization; in other words, the amount of capital stock proposed for the company; what portion of it is to be offered for the cash required, and how that cash is to be supplied, and on what dates.

In estimating the amount of capital required, remember that in planning underground work one is dealing with an unknown quantity to a certain extent. Water may be encountered; broken ground, slips, quicksands, etc., all of which may cause abnormal expense; and provision for these is what is meant by a surplus beyond visible needs. There is nothing more irritating to a capitalist than a deficiency in an estimate. It is always embarrassing to the engineer and tends to undermine the confidence of his associates. It is not usually difficult to have estimates accepted at the beginning to cover all reasonable contingencies; so make the fight then, fairly and consistently, for if you do not, but permit your estimates to be cut to such an extent that the company eventually runs short of money, the capitalist will not infrequently require a concession from the original terms. This involves a sacrifice on the part of the promoter, and may put him in such a pinch as to enable the capitalist to dictate his own terms for future contributions. Hence the necessity for liberal estimates of cost, which is the first item in considering capitalization. The second item is the interest of the capitalist. The third relates to the interest which the promoter is to retain for himself. If the promoter does not own the prospect, there would be a fourth item, namely, the consideration which the owner is to receive. The estimates of cost and the price of the property will be fixed sums. The interests of the capitalist and the promoter will be first adjusted on the basis of percentage. For illustration we will assume the price of the prospect

to be $5000; the engineer's estimate for carrying the development up to an agreed stage, $10,000; estimate for unforeseen contingencies, $5000; the interest of the capitalist twice as much as that of the promoter and sufficient for him to remain in control.

When trying to interest capital, do not think to hold control of the enterprise. When a capitalist puts money into a venture, he expects and demands the controlling authority in matters of policy, the composition of directorates, etc. If you insist on managing the whole affair yourself, you will be unable to enlist assistance from capital. What you ought to do is to work into a partnership with your capitalist, with the certainty that if you make good in working for your joint interests, your abilities are bound to be recognized; while if you are unable to handle the enterprise in a satisfactory manner, the capitalist will and ought to insist that a competent man be put in charge to avoid wrecking the entire enterprise.

To begin with, you want in cash, on this basis, $20,000. Here is a basis for the company:

Capital stock - - - - - - -		$100,000
Stock to capitalist for contribution of $20,000 - - -	$50,000	
Promoter's share, half of this	25,000	
Treasury stock - - - -	25,000	

This remaining $25,000 of treasury stock will be found useful in case expenditures exceed original estimates; and if operations be successful it can be sold at a greatly enhanced price for further development. And here arises the question, what is the value of any interest, for example, the promoter's? Although it is evidenced in $25,000 of the capital stock, intrinsically it cannot be expressed at all. Its money value must remain to be created by the results, but its value in proportion to the capital stock of the company and the other interests, is at once and for all time determined.

The capital of a stock company, as has been stated, may be sub-divided into common stock, preferred stock, bonds, and debentures. All these are commonly termed securities. Another security often issued by a corporation, is called a collateral note, which is not, however, an integral part of the so-called capital, but supplementary thereto.

Preferred stock may be stock having preference as to the assets of the company, or preference as to dividends, or both. The preference as to dividends may be ordinary, fixed, cumulative, or non-cumulative. If preferred stock has preference as to dividends and preference as to assets, then the dividend on the preferred stock must be paid before there can be any distribution for the account of the common stock, and in case of liquidation, which means winding up the affairs of the company, the preferred stock would be liquidated before the common stock. Liquidating the stock means reimbursing the owner thereof, in so far as there may remain any assets after settlement of the company's obligations. Sometimes it happens that preferred stock is issued under the condition that it shall be liquidated at a small premium of five or ten per cent, in which event the preferred stock must receive that before the common stock is considered. The participation of preferred stock in the profits of an undertaking may be limited to a fixed percentage, in which event all further profits would be enjoyed by the owners of the common stock. This would be designated as fixed or non-participating preferred. Or, it may be preferred to a certain percentage, after which, the common stock having received a like amount, both classes of stock would divide any remaining surplus equally. This would be 'participating preferred.' For instance, a company having $100,000 in common stock and $100,000 in preferred 5% stock earns for distribution 4% of the entire amount, which equals $8000. In that case a dividend of 5% would first be paid on the preferred stock, requiring $5000, leaving the remaining $3000 for distribution on the common stock, equal to a dividend of 3%. Now, suppose that instead of producing a profit of $8000, it produces a profit of $18,000. This would allow a dividend of 5% on the preferred stock, requiring $5000, leaving a balance of $13,000. This would allow a dividend of 5% on the common stock, leaving the balance, $8,000 to be divided equally between the common and the preferred stock. This would amount to $4000, or 4% additional, on common and preferred stock. In this case, both common and preferred stock would receive a dividend of $9000, or 9%. Finally, if the profit were only $5000 or less, the whole of it would go to the preferred stock. When preferred stock is described as cumulative it means that if the requisite preferred dividend is not paid in any given year, the unpaid dividend stands as an accrued charge against the earnings. It must be paid in some future year, together with all subsequent accruing dividends, before the common stock can receive anything. A case in hand would be that of a company with 5% preferred stock having had two lean years yielding no profits for distribution, followed by a fruitful year with large earnings. The preferred stock would then be entitled to dividends on the two lean years, and also on the fruitful one, before the common stock would receive anything; which explains the term cumulative. Preferred stock may have conditions permitting exchange for common stock within a fixed time. It often happens that the dividends on the fixed preferred stock may absorb the entire earnings of the company for a few years, and afterward the earnings may increase sufficiently so that the dividends on the common stock may be more than those on the fixed preferred, in which event the common stock would be the most desirable; and holders of the fixed preferred would then relinquish it in exchange for common stock.

Obviously the only reason why a company should issue preferred stock would be to give the holders thereof a prior claim upon the earnings of assets of the company as an inducement for investment. This frequently conceals what is known as a 'joker.' Sometimes a shrewd promoter knows that while the earnings of his company may be small in the begin-

ning, they will increase enormously in the future. He issues preferred stock at a liberal fixed rate, say six or seven per cent, with the avowed purpose of giving the investors preference, knowing that ultimately the earnings will be sufficient to pay more than that rate to the common stock, which he holds himself. In that event, while the investor is preferred in theory, in practice he is not.

In taking up an enterprise, the capitalist or syndicate will frequently insist that the money contributed shall receive a fixed rate of dividend before the promoter receives anything. Such a case is met by the issuance of preferred stock. It often happens in large companies that the amount of preferred stock is so great as to make it perfectly apparent that it will absorb all earnings that may be expected for years, and yet the same company may have out a large amount of common stock. A layman could neither see the use or value of that common stock; however, as every share carries a vote and the preferred stock carries no more, the common stock gives to the party or clique controlling it the power to govern the affairs of the company. In such a case it would have been created for that purpose. Preferred stock is sometimes created with a provision for a sinking fund, which means that a certain fixed sum shall be set aside from earnings at stated intervals, to be ultimately used for the redemption of the stock to which it relates. When that stock is redeemed it bears no further relation either to the dividends or assets of the company, and is cancelled.

Stock subject to no preferential conditions is called common stock, in contradistinction to the preferred; and the stock of all companies is common unless otherwise designated.

A corporation bond is an instrument which is the evidence of a debt secured by a mortgage on all, or a portion of the assets or income of the corporation. Bonds secured by a first mortgage are called first mortgage bonds; if secured by any subsequent mortgage they would rank in succession as second or third mortgage bonds, etc. If secured by income they would be designated income bonds. The bonds of a company are created for a specific indebtedness. Each bond stands for such integral part of that indebtedness as is nominated on its face, and the amount so expressed is the par value of the bond. Their particular function is to divide that indebtedness into small units. Corporation bonds are generally created to provide for indebtedness which is to exist for a long term of years. They are designated according to the term for which they are issued and the rate they bear. A bond bearing 5% interest, due in 40 years, would be termed a 5% 40-year bond. They may be registered, in which event, neither principal nor interest could be collected by other than the registered owner. They are not usually registered, and unregistered bonds are negotiable by any holder, the passing of possession conveying the title.

As bonds are usually created in large issues, in order to facilitate collection, payment, and identification of interest, there are usually coupons attached to the bond representing the amount of each installment of interest and maturing on the date when the interest is due. These coupons are cut off on their due dates and forwarded to the proper place for collection. They are evidence as to whom the interest may be due, and when paid and passed into the hands of the payer, form a receipt for the payment thereof. Being secured by a mortgage on the assets of a company, bonds are a preferential security. There is a large class of persons investing in bonds that would not for a moment consider an investment in stock, as the latter must depend upon the success of an undertaking. Business might fail and stock be worth nothing, and yet the bonds be safe, provided the basis on which they were issued was sound; in other words, provided the assets on which they have preference were of sufficient value. Bonds do not share in the profits of a company, consequently the bondholders do not reap any gain beyond the rate of interest paid, with the exception of a small premium to which a bond may advance if it may be fancied by the public. Bonds are not usually issued by mining companies, because in order that they may sell readily, they must be secured by good, convertible, visible assets sufficient to pay principal and interest, and leave a good margin for contingencies.

A debenture is an instrument like a bond, promising to pay a certain principal sum, together with interest, on stated dates. They have all the physical characteristics of bonds but are not always secured by mortgage. They are a favorite form of security in Europe, but are not much used in the United States.

Collateral notes are promissory notes issued by a corporation, usually in sums falling due at different intervals, and secured by the company's bonds and stock. They generally serve a temporary purpose and sometimes provide for emergencies. At this time, when we are discussing the subject, interest rates are unusually high, and people having money to invest are not tempted by the 5% bonds that are usually issued. A company depending for its money upon the sale of its 5% bonds must resort to some means to pay the investor a higher rate and still give him security, but merely, however, as a temporary measure. The 5% bonds can be sold for 70% of par, which would net the investor about 7% per annum as interest, but in the end the company would be requested to redeem the bonds at par and would thereby lose thirty points; the difference between 70 and par. To meet this case, a company requiring a million in cash would deposit a million and a half of its 5% 40-year bonds with a trustee as security, and issue against that security one million in 7% collateral notes, maturing in two or three years. The public would then have a security paying 7%; the company has provided an expedient to meet the prevailing abnormal rate of interest; and still has not parted with its bonds, which can be sold at par, in normal times, and the collateral notes be paid from the proceeds. While the collateral notes are properly called securities, they are not a portion of the issued capital, and do not in reality increase the company's liability, because they are paid out

as a substitute for such part of the authorized capital as is meantime held in trust against them.

Companies are often created and business launched without the co-operation of outside capitalists. A case in hand applicable to his discussion would be one where four or five persons might wish to join for the purpose of opening up a prospect owned by one of the number. We will suppose that A owns the prospect; B is willing to contribute $1000; C, $500; D, $300; and E, $200. In a case like this, all that is necessary in forming the company is to decide what relation the prospect is to bear to the total capitalization, and to fix an arbitrary sum as the capital stock. We will assume an agreement that this prospect is to rank for one-quarter interest in the issued stock of the undertaking. A basis would then be the following:

Total capital stock - - -	$25,000
Reserved in treasury - -	5,000
Total available - - -	$20,000

A, the owner of the prospect, will have one-quarter of the available stock, leaving $15,000 in stock to be distributed pro rata among B, C, D, and E. The total amount of cash involved is $2000. B pays $1000 or 50% of the amount, C pays $500 or 25%, D pays $300 or 15%, E pays $200 or 10%. For convenience we will assume that the stock is divided into shares of $1 each. Then,

B's portion would be 50% -	7,500 shares
C's portion would be 25% -	3,750 "
D's portion would be 15% -	2,250 "
E's portion would be 10% -	1,500 "
Total - - - - - - -	15,000 "

Here again we have an example showing that the stock of the company is an apportionment of interest but not a measure of value, for while the former is accurately expressed, in this illustration the actual cash value still remains an unknown quantity.

The legal methods for the formation and operation of an incorporated company are clearly prescribed in the statutes of the different States. They are properly within the functions of the attorneys who should be retained for the proper safe-guarding thereof, and barring necessary compliance with the law, are of secondary importance. A company may be formed under the aegis of the most distinguished legal counsel in the world, but without the non-technical requirements for success, it will avail nothing.

In order to make the securities of a company attractive there must not only be intrinsic value as its basis, but also an earning power commensurate with the expressed value of the stock for dividend distribution. Leaving the legal steps under proper supervision, the promoter will be chiefly concerned with the amount and classification of the securities, the provision of proper channels through which they may be subscribed, the selection of directors and the formation of the directing board, and the necessary provision for his own compensation or profit. The selection of directors and the formation of the board is most important because into their hands the promotor must entrust his enterprise. It requires a rare kind of a man to become an ideal director, and he should be able to qualify as to five requirements, namely, he should be familiar with corporate affairs; he should be a man in whom the public has confidence; he should himself have sufficient confidence in the undertaking to invest his own money in it and induce others to do the same; he should be liberal-minded enough to treat the promoter fairly, regardless of the latter's necessities; and he should be a man of staunch integrity, resourceful, and conscientious in performing his corporate duties. In selecting these directors many things have to be taken into consideration, and usually this is undertaken in conjunction and simultaneously with negotiations for supplying either a portion or all the capital needed.

In company promotion an underwriter is one who insures the furnishing of money. When the statement is made that a certain company or amount of securities has been underwritten, it signifies that either persons, firms, or syndicates have guaranteed to purchase the securities at a stated price. Most large issues reach the investing public through the medium of underwriters, who make a legitimate commission. The commission is legitimate, because they provide immediately for the necessities of the company, enabling its operations to be inaugurated and to proceed unhampered while the underwriters are finding a market for the securities. Usually the directors, or most of them, are found through the underwriters, or the underwriters through the directors, as the two generally bear intimate relations. The promoter, however, should, so far as he can without detriment to the company, endeavor to have men of his own selection for directors.

There are leading spirits in every organization; it is not unusual to see a board practically run by a small minority of its members, whose technical skill, or money power, or aggressiveness, or some other influence, keeps them in the lead. Such men should be sought out by the promoter, after he has clearly planned his own program, and they should be enlisted in the preliminary stages of his negotiations. All details should be arranged by and through them, so that when the full board is finally formed those members who join later may do so on a settled plan, which is accepted without further discussion.

Incorporation furnishes the best known method of enabling units of capital to combine into a large aggregate without the undesirable features of the co-partnership. Although there is a community of interests between the stockholders of a company as there is between the members of a firm, and all share in the business in proportion to their holdings, yet we have seen the advantages the former has over the latter, even when many persons are interested. Capital stock serves as a means of apportioning interests, but not as a measure of value; the par value of each share may be anything to suit convenience. A company may have preferred and common stock, and also bonds, which have preference over both classes of stock. The legal steps in company forma-

tion are defined by statute in each State. The basis of capitalization and personnel of the directorate should be planned by the promoter. He should arrange all preliminaries with a small committee whenever practicable. Capitalists will often invest in a corporation when they would not do so in a copartnership.

In approaching a capitalist, remember that he is generally greedy, timid, and usually busy; therefore make your presentation in such a way as to cover all those points. The promoter's position should be surrounded with all possible safe-guards and his proposition should be concise, convincing, methodical, and definite. Don't leave the capitalist to think out your basis for you. Your own thinking apparatus is better for you than his. Always estimate on a liberal basis for cost and a conservative basis for earnings. In seeking large amounts of capital try to arrange in the beginning either with one or more individuals or firms to underwrite all that may be needed.

We have discussed within very narrow limits the subject of company promotion and suggested certain bases. In practice the methods of proceedure will not differ materially, but the basis for each transaction must be adapted to the case in hand. When you leave these college halls and go out into the world you have a clear field. There are as yet no professional mistakes to explain, no financial failings to condone. At that moment the public is your patron, the wide, wide world your field; and while every success increases your influence in that field, each failure diminishes your clientele and circumscribes the limits of your horizon. The greater the intelligence possessed on all subjects relating to your business, the greater will be your earning power; hence this address. One may be a successful company promoter without any conception of mining engineering or other technical subjects, but the most successful mining engineers have been those who have had a broad conception of corporation affairs in their bearing upon the acquisition of property for company flotation, and its relation as a basic item to the capital stock of the company, having in mind the cost of acquisition, the cost of development, and the probable return; because those men not only made technical reports, but have been able to recommend to their clients practical bases for presentation to the public. So, while you can win a diploma here upon your technical showing, which will give you ample warrant to advise your clients what to put money into, and what not, you will not have reached the zenith of your earning power until you can likewise show your client how to get his money out again at a profit. And the quickest way is always to form a company, on such lines that the public will buy the stock at a profit.

Electrical air filtration is suggested by an English experimenter, who has discovered that a body positively electrified to 100 volts or over will, if placed in a sooty atmosphere, become covered with soot in a day, while a negatively charged body remains comparatively clean.

THE CARAT WEIGHT.

By E. J. VALLENTINE.

*The use of the carat weight by dealers in gold and precious stones extends over a considerable period of the world's history. According to Dr. Ure, carat was the name of a red bean which grew in the district of Shangallas, in Africa, at one time a famous mart for gold dust. As these beans were remarkably uniform, both in size and in weight, they were adopted by the traders as a standard; they were transported to the East and used in the weighing of precious stones. Morion, however, states that it is derived from the Arabic, *kirat*, signifying weight, and thinks this may again be derived from the Greek *keration*, a small weight. According to Anania de Schiraz, a Syrian authority of the sixth century, the carat or diamond weight was originally taken as the $^1/_{144}$th part of an ounce (*uncia*), twelve of such ounce constituting a mina. The mina, which was derived from the lessor or silver Alexandrian talent, was adopted by the Romans during their occupation of Egypt. As it weighed 5460 gr., the weight of the original diamond carat was, therefore, 3.15972 gr., or only 0.0086 gr. less than that of the present British diamond carat.

A carat gold weight was used in England until recently. It was a unit in a now obsolete system of weights known as 'refiner's weight.' This system, which was used in reporting gold assays, was as follows:

12 oz. = 24 carats.	1 gr. = 4 quarters.
1 carat = 4 gr.	½ gr. = 15 gr. troy.

Until 1882 these weights were used at the Royal Mint in reporting gold assays, 1 carat-lb. being taken as equal to 24 carats of 5760 gr. troy. The amount of pure gold contained in a carat-pound of bullion was expressed in carats; for instance, 22 carat gold (the 'standard' gold from which our gold currency is coined) contains 22 parts of pure gold to two parts of alloy. Although the carat weight is now obsolete, this system is still used by goldsmiths in stating the fineness of the gold of which their wares are made. It has, however, been discarded by assayers and metallurgists in favor of the millesimal system, in which pure gold is taken as having a fineness of 1000. On this latter system, 22 carat, or 'standard,' gold is therefore $^{22}/_{24}$ of 1000 = 916.6 fine.

The carat used in weighing precious stones is a much smaller weight than the obsolete gold carat. It is generally known as the diamond carat.

The diamond carat of 3.1683 gr. is equal to 205.3022 mg. The following sub-divisions are used by diamond merchants: ½, ¼, ⅛, $^1/_{16}$, $^1/_{32}$, $^1/_{64}$, the sixty-fourth part of a diamond carat being known as a 'part.'

Diamonds are usually found in placer deposits, except in the case of the eclogite pipes in South Africa. In Central India and Brazil they occur in conglomerate and gravel, and are associated with a peculiar flexible sandstone, but the matrix of the diamond has not been discovered in either of these deposits.

*Abstracted from Bull. 45, Institution of Mining and Metallurgy.

MINING AND METALLURGICAL SOCIETY.

Constitution and By-Laws adopted at meeting held in New York on April 20, 1908.

Constitution.

1. The name of the association shall be Mining and Metallurgical Society of America.

2. The association shall have for its objects the conservation of mineral resources, the advancement of mining and metallurgical industries, the better protection of mine investors and mine workers, the increase of scientific knowledge, and the encouragement of high professional ideals.

3. The society shall comprise Honorary Members and Members who must be qualified by knowledge, experience, and honorable standing to advance the objects of the association, and shall be proposed for and elected to membership as provided in the by-laws of the society.

4. All interests in the property of the society of persons resigning, or otherwise ceasing to be members, shall vest in the society. No member or officer shall receive salary, compensation, or emolument unless authorized by the by-laws, or by concurring vote of two-thirds of the executive council. Members residing for a year or more beyond the limits of the United States, Canada, and Mexico, shall not be entitled to vote nor hold office during the period of such residence.

5. The affairs of the association subject to the provisions of the constitution and by-laws shall be managed by an executive council of not less than fifteen managers, who shall hold office for the prescribed term or terms, and who shall elect from their own number, a President, not less than four Vice-Presidents, a Secretary, and a Treasurer, who shall hold office for one year, or until the close of the meeting at which their successors in office are elected, and who shall be eligible for re-election. Additional officers may be elected by the executive council from time to time if necessary for the purposes of the association.

6. The annual meeting of the association shall be held on the second Tuesday in January of each year. One-third of the members, present in person or by proxy, shall constitute a quorum for the transaction of business.

7. The association may adopt by-laws, rules, and regulations for the conduct of its business provided that these are in harmony with this constitution, and may provide different methods for amending or repealing such by-laws, rules, and regulations.

8. Amendments to the constitution may be presented at a regular or business meeting of the association; and if endorsed by the council or in writing signed by at least twenty members, a copy of such proposed amendment shall be sent to all entitled to vote, accompanied by comment by the council if it so elects, at least thirty days in advance of a second meeting called for its consideration; at which meeting the amendment may be amended as to wording but not as to intent, and then shall be submitted to a final vote by sealed letter ballot sent to all members; the polls shall be open for sixty days, and for the adoption of the amendment a majority of those entitled to vote shall be required to have been recorded in the affirmative; provided, however, that a negative vote comprising a majority of the votes cast shall defeat the amendment. If the necessary vote for adoption or for rejection is not secured on the first ballot, the council shall order the sending of a second ballot by registered mail to members who have not recorded their vote; and in such case, so many of these second ballots as have been received by members, if not voted within a further period of sixty days, shall be counted as votes cast in the affirmative. The ballots shall be voted, canvassed, and announced as provided in the by-laws.

By-Laws.

1. A candidate for membership shall submit in such form and in such detail as may be prescribed in the rules and regulations of the council a statement of his professional experience. The candidate must have had eight years practical or professional experience, including not less than five years in positions of responsibility, in mining or allied lines of work. Graduates of approved engineering schools shall be credited with one-half the time prescribed for graduation. The candidate must be endorsed by three or more members who shall further certify as to his qualifications for membership in writing. These statements must be based on long or intimate personal knowledge, and shall be submitted in such manner as the council may direct. The candidates must be approved by the council, and elected by sealed letter ballot, sent to all members of the association entitled to vote. Adverse votes, received within sixty days, amounting to five per cent of the votes cast, shall be required to defeat the candidate. A candidate may renew his application a year or more after his rejection.

2. Honorary Members, not to exceed ten in number, must be proposed in writing, setting forth at length the qualifications of the candidate, and signed by at least twenty members of the association. The candidate must be elected by vote of the council, which shall be by sealed letter ballot. One dissenting vote shall defeat such election. Honorary Members are not entitled to vote nor to hold office and shall not be required to pay initiation fees nor annual dues.

3. All elected candidates shall be duly notified and shall subscribe to the constitution and by-laws in such form as the council may direct. This latter provision shall not apply to Honorary Members.

4. There shall be an initiation fee of twenty-five dollars for each new member after the total membership reaches two hundred and fifty.

5. The annual dues shall be ten dollars, payable in advance in January of each year. The council may in its discretion permit any member not in arrears to become a life member on payment of an adequate sum for the purpose based on his expectation of life according to reliable tables of mortality.

6. The membership of any person in the association may be suspended or terminated for reasons of weight by a four-fifths vote of the executive council. Notice of such intended action shall be sent to such

member by registered mail and action shall not be taken for at least thirty days after the receipt of this notice by such member. A member suspended or expelled may demand a sealed letter ballot sustaining the action of the council. This ballot shall be sent to all members entitled to vote and may be accompanied by a statement signed by the council or a committee thereof, and by a statement on behalf of the accused of not more than one thousand words, or not exceeding in length that prepared by or for the council. A majority of the votes received within thirty days shall be required to reverse the action of the council.

7. The executive council shall from time to time divide the territory occupied by the membership into fifteen geographical districts to be designated by numbers. Each of the districts shall be, as nearly as practicable, contiguous territory; each shall contain as nearly as practicable an equal number of members. The council shall announce such division to the association three months before the annual meeting. There shall be at any one time not more than fifteen managers, one from each district, whose term of office shall be so arranged that five of them shall retire each year.

8. Three months before the annual meeting the secretary shall send a nomination ballot to each member of the association in the districts for which new managers must be elected, with the request that he shall nominate three members, in such manner as the council may direct, as candidates for manager to represent his district. Nominations shall be received for twenty days when the polls shall be closed. Sixty days before the annual meeting the secretary shall prepare a ballot, containing in and for each of these districts not less than three names, which shall be in each case those receiving the largest number of nominating votes before the closing of the polls. This ballot shall be mailed to each member entitled to vote, who may vote for one manager in each district, having the right to substitute names not on the list, and to cast not over three votes for a single candidate, provided that the total number of votes cast by such member shall not exceed the total number of vacancies to be filled. The ballot shall be signed, sealed, and voted as prescribed in by-law 15.

9. At noon of the first day of the annual meeting the polls shall be closed and the ballots counted by tellers appointed by the President. Managers shall not be eligible for such appointment. The candidate in each district receiving the largest number of votes shall be elected. In case of a tie the President shall cast the deciding vote.

10. The term of office of a manager shall begin immediately upon election. Vacancies occurring at any time in the council may be filled until the next annual election by a majority vote of the remaining members. At the next annual election new managers shall be elected to fill such vacancies for the unexpired term of office only.

11. The officers of the association, as provided in the constitution, shall be elected at the annual meeting, or whenever a vacancy occurs, by a majority vote of the council. Their term of office shall begin at the close of the meeting at which they are elected. For reasons of weight any office, except that of manager, may be declared vacant by a two-thirds vote of the council. The duties of the several officers shall be such as usually attach to the office or such as may be determined by the council. The council may delegate its powers to persons or committees, and may make such rules and regulations as may be necessary for the proper conduct of the business of the association, provided that these are in harmony with the constitution and by-laws.

12. Meetings of the council for the transaction of business may be called at any time by the President, and shall be called at the request in writing of three managers. Unless for reasons of weight at least ten days' notice of meetings shall be given. Five managers shall constitute a quorum. A letter ballot of the council shall be taken on any question of importance if so ordered by the presiding officer at any meeting, or at the request in writing of three managers.

13. The council shall provide for regular stated meetings of the society for the transaction of business or for the reading or discussion of papers to be held at such times and places as may best serve the interests of the association. Special meetings of the society or of any section thereof, for a definite purpose, may be called by the President, or shall be called, on a request in writing signed by twenty members. It shall not be in order at a special meeting to discuss other business than that stated in the call for the meeting. Except for reasons of weight, at least thirty days' notice shall be given of all meetings. Except at annual meetings ten members present in person or by proxy shall constitute a quorum. Resolutions endorsing or condemning matters of public or professional interest shall take the course prescribed for amendments to the constitution. Other matters of importance, by vote of members present at any meeting, or by direction of the presiding officer, or by vote of the council, may take the same course.

14. Local sections or professional groups of members of the society may be organized for social, scientific, and professional purposes in harmony with the constitution and by-laws, and such sections shall have such powers, and shall act under such rules and regulations as the council may from time to time approve.

15. When sealed letter ballots are required by the constitution or by-laws, the envelope to contain the ballot shall be so designed that it may be signed on the outside by the voter for identification, and may afterward be opened by the tellers so as to preserve the secrecy of the ballot. The endorsement may take the form of a proxy, to be voted by the tellers appointed by the President, or by such other person, not a manager, as the member may designate. The ballots signed and sealed shall be mailed or delivered to the secretary, who shall be responsible for their safe-keeping, and who shall endorse thereon the date and time of receipt and make record of such receipt on a list of members kept for the purpose. Any member shall have the privilege at any time

before the closing of the polls, of substituting another ballot, in which case the original shall be returned to him unopened. After the closing of the polls the ballots, arranged in alphabetical order, with the check list of members above mentioned, shall be delivered by the secretary to tellers appointed by the President. The tellers shall verify the check list, and open and mix thoroughly the votes in such manner as to preserve the secrecy of the ballot. The ballots after being counted by the tellers shall be destroyed, and the report of the tellers shall be the official record of the vote. In case a supplementary ballot shall be ordered for members failing to vote on the first ballot, the members whose votes have been counted shall not be permitted to vote a second time nor to change their original vote. The result of the ballot shall be communicated to the members of the association at such time and in such manner as the council shall determine, and shall be announced by the presiding officer at the next business meeting of the association, and recorded on the minutes.

16. The council shall by a two-fifths vote of its members, and shall upon request in writing of twenty per cent of the members of the Society, make any important question submitted to the membership a vote of confidence. In case such question is decided against the council the members shall resign office, their resignations to take effect on the election of their successors, and a new election of the whole executive council shall be ordered to be conducted as provided in the by-laws. The new council shall by lot divide themselves into three classes to serve until the next annual meeting and for one and two years thereafter respectively.

17. Amendments to the by-laws shall take the course provided for amendments to the constitution, save that when the letter ballot is taken a majority of the votes received within thirty days shall pass or defeat such amendments.

Mount Lyell. The Mt. Lyell Mining & Railway Co. has just installed at its reduction works, Queenstown, Tasmania, two large turbo-blowing engines and these along with the smaller one, which has been in use for a year, will make the finest blowing plant in Australia. The smoke from the smelter has destroyed all vegetation within a radius of eight or ten miles, but since the district is not agricultural the company is not troubled with lawsuits on this account. No doubt the great amount of rain, while it keeps the district clean and healthy, has contributed to intensifying this injury. The climate while wet is equitable, there being no cold weather or snow, it being rare that there has been any ice forming more than 1/8 inch thick. The practice in pyritic smelting at the works is yet advancing, and indeed those responsible for its improvement maintain that its possibilities have not been nearly grasped.

Another record for flight on aeroplanes was recently established by Leon de la Grange, of Paris, who was aloft for 555 seconds. However, his wheels touched the ground at intervals, so that he was above touching distance of the earth for 390 seconds, in which he covered about 21½ miles.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

A mining claim located on the lands of the United States is still a part of the public domain, and although proceedings may have been begun by the owner of the claim for the acquisition of title to the land by patent, still the land itself is not subject to taxation by State authorities.

Elder *v.* Wood, 28 Sup. Ct. Rep. 263, Jan,, '08.

An oil and gas lease gave the lessee the exclusive right to drill for gas, oil, or coal for a specified term, and as much longer as any of these could be found in paying quantities. The consideration of the lease was one dollar and a royalty of eight cents a ton on coal mined, and fifty dollars per annum for the gas produced from each well, and sufficient gas to supply stoves in the lessor's farm-house; but no grounds of forfeiture were stated. In an action to cancel the lease the court decided that the law would construe such lease as if it contained a stipulation expressly written therein to the effect that the lease should be forfeited if the lessee failed within a reasonable time to carry out the purpose of the lease.

Mills *v.* Hart, (Kans.) 94 Pac. 142, Feb., 1908.

Where it appeared that the mine boss in charge of the mine had knowledge of the dangerous condition of the entry to the mine, this was held to constitute notice to the owners.

Smith *v.* Garrison, (Ky.) 108 Southwest. 293, March, '08.

Where the dangerous condition of the entry of a mine was known to the operators of the mine, it was held that a miner who was injured by a fall of rock from the side of an entry, without any notice or knowledge of its dangerous condition, was not required to examine or inspect the entry closely in order to ascertain its condition.

Smith *v.* Garrison, (Ky.) 108 Southwest. 293, March, '08.

A miner was employed to drive an entry in a mine. He was injured while engaged in assisting others to set a prop at a place where the entry had been completed, and where it was the duty of the owner of the mine to protect the roof of the entry; he had received no directions or instructions to set the props or to protect the roof of the entry. But the mine owner had failed to perform his duty in this respect although he had promised to do so. The miner was in the entry at his proper place and performing his work, when the necessity arose to try to protect himself and others against certain slate which was about to fall, and which did fall, between them and the mouth of the entry of the mine. The miners could not know in advance the extent to which the slate would fall, whether it would cut them off from leaving the mine or not, and in addition to this they could not perform their labor and run the cars into and out from the slate which was knocked down from the roof, if this slate was permitted to fall. Under such circumstances the miner was within the scope of his employment; the propping of the roof was a thing necessary to be done for the protection of the miners and of the property of their employer.

Ballon *v.* Potter, (Ky.) 106 Southwest. 1178, Jan., '08.

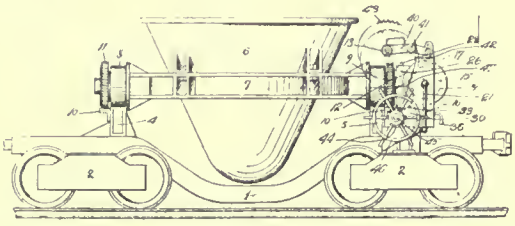
A tenant in common of a mining claim who incurred expenses in prospecting, without the consent of his cotenants, was held not entitled to recover contribution from them. But where one tenant had operated a mine and was sued by his co tenants for an accounting for the profits, the operating tenant was held to have the right to set off as against such non-operating tenants the cost of the necessary improvements, on proof that the improvements were necessary and increased the value of the common property.

Wolfe *v.* Childs, (Colo.) 94 Pac. 292, March, '08.

MINING AND METALLURGICAL PATENTS.

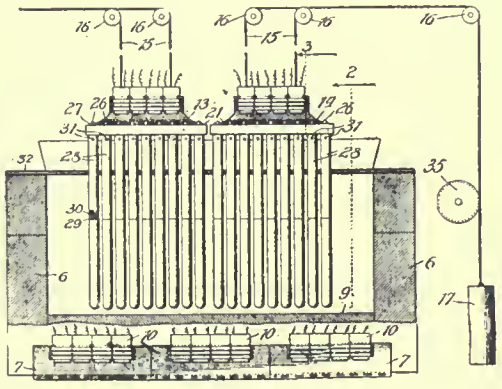
Specially Reported for the MINING AND SCIENTIFIC PRESS.

DUMPING-CAR.—No. 882,129. Munson H. Treadwell, New York, New York.



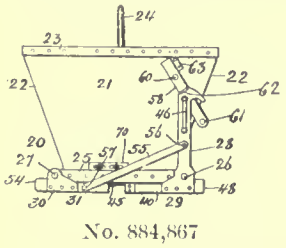
In a dumping-car, the combination with a movable car body, and manual means for moving it to discharging position, of means independent of the manual actuating mechanism for controlling the rate of movement of the car body, substantially as described.

ELECTRIC FURNACE.—No. 881,518. Charles E. Wilson, Ferris, West Virginia.

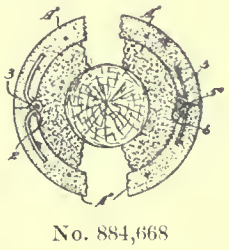


In an electric furnace, the combination of a melting chamber, an electrode in the base of the chamber forming a lower terminal of the electric-current supply, a plurality of suspended and independently adjustable heads above the said chamber independently connected with said supply, and a suspended electrode removably mounted in each of the said heads, the suspended electrodes forming together an upper terminal, in the chamber, of the electric-current supply, whereby the electrode at one head may be renewed while the current passes through the other suspended electrode, for the purpose set forth.

SELF-CLOSING DUMPING-BUCKET.—No. 884,687. Gustavus L. Stuebner, Flushing, New York.



No. 884,867



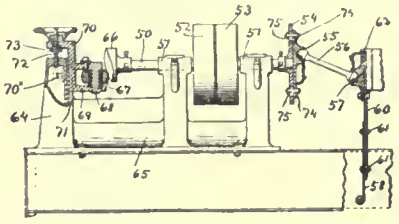
No. 884,668

In a bucket the combination of a body, a swinging bottom fulcrumed thereto, a counter weight on the bottom, a latch arm extending from said bottom, a latch lever fulcrumed to said body in the path of the latch arm, a stop in the path of the upper swinging end of the latch lever to control the amount of downward swing of the lower end thereof, the latch lever and latch arm engaging with each other when the bottom is closed against said body, and tightening against each other with any increase of load in said bucket.

CONCRETE PILE-COVERING.—No. 884,668. Frederick A. Koetitz, San Francisco, California.

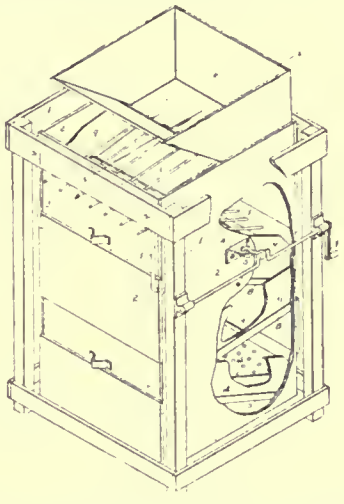
The combination with a pile, of a hollow concrete casing made in segments hinged together along one of their longitudinal edges, and means for detachably securing the opposite edges of said segments.

DRIVE MECHANISM FOR ORE-CONCENTRATORS.—No. 882,512. George E. Woodbury, San Francisco, California.



In a drive-mechanism for an ore-concentrator, the combination with the concentrating table, of a rotatable and longitudinally movable shaft, a head on one end of the shaft, a toggle-bar interposed between said head and the end of the concentrator-table; a cam-faced disk on the opposite end of the rotatable shaft having a gradually increasing elevation of surface from a line of lowest depression both radially and circumferentially to a line of greatest elevation, a roller rotatably mounted and in working-contact with the face of said disk, and a spring adapted to apply its power in opposition to the thrust of the toggle-bar.

APPARATUS FOR SEPARATING GOLD.—No. 883,861. John A. Creasy, Norborne, Missouri.



In an apparatus for separating gold, the combination with a suitable frame of a casing suspended from and within said frame and provided with pan openings at the front and back, means in said casing for supporting pans, and pans adapted to seat on said supports and for insertion into and removal from said casing through said openings, the bottom edges of each of the upper pans being projected partially within the pan next there below substantially as set forth.

ELECTROMETALLURGICAL PROCESS FOR EXTRACTING COPPER FROM ITS ORES.—No. 883,961. Lucien Jaman, Paris, France.

The herein described electrolytic process for obtaining pure copper from its ores, which consists in lixiviating the ores with an ammoniacal solution, precipitating the copper from said solution in the form of a precipitate containing cuprous sulphite, dissolving said cuprous sulphite in an ammoniacal solution, and in subjecting said last solution to electrolytic action in the presence of carbonate of ammonia.

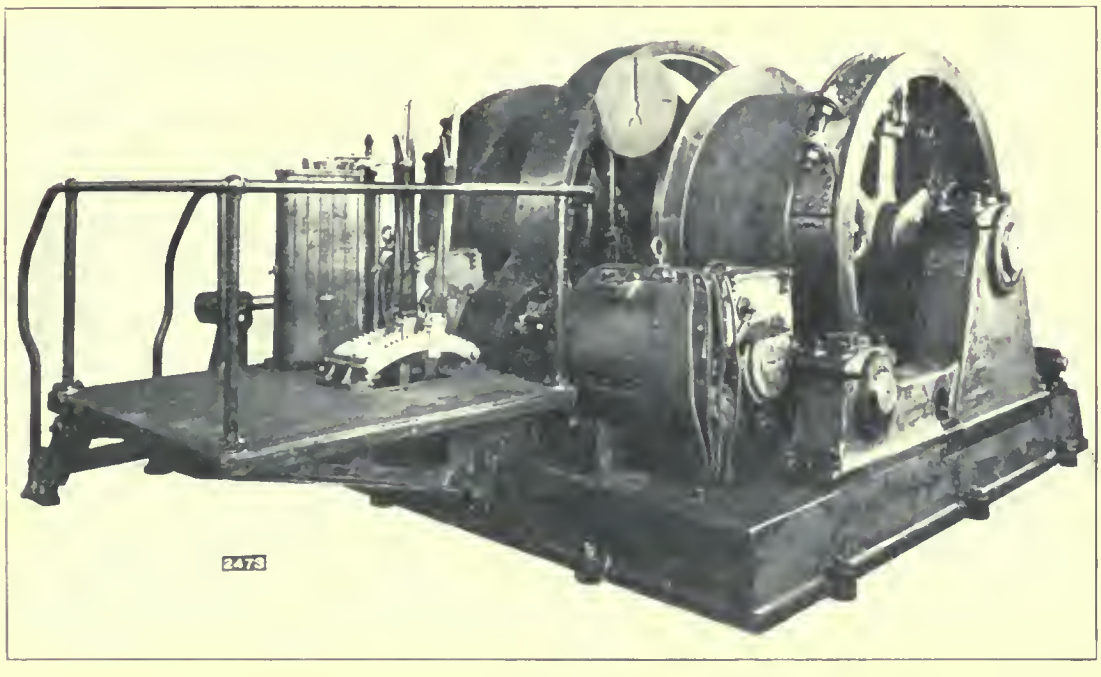
METHOD OF REDUCING LEAD ORES.—No. 882,193. Alfred Francis, St. Louis, Missouri.

The method of treating sulphide ores of lead or concentrates of such ores, which consists in melting ore having fluxes and fuel mixed therewith to produce an approximately pure lead matte, allowing said lead matte to flow onto a bath of molten lead, and blowing air into said bath of molten lead to oxidize the lead and convert the matte into metallic lead; substantially as described.

A NOVEL ELECTRIC HOIST.

The hoist shown in the accompanying illustration was built by the Vulcan Iron Works of Wilkes-Barre, Pennsylvania, for the Hallidie Machinery Co. of Seattle, Washington, for use in the mines of the Carbon Hill Coal Co. It is of the self-contained type, driven by two No. 83 Westinghouse railway-type motors, operating at 550 volts direct current, each motor having a capacity of 110 hp. half-hour rating. The motors are secured to the bed-plate by nose-spring suspension, thereby eliminating the shock occasioned by starting heavy loads. Both motors are mounted on a heavy steel shaft. Between the motors is the main driving pinion, the whole being supported on three babbitt-lined pedestals. The motors are controlled by a type R-6 controller, with separate reverse handle, eight points forward and eight reverse.

Each drum has a capacity for winding 1500 ft. of 1⅛ in. wire rope in three layers, the rope-pull being about 10,000 lb. at 600 ft. per min. At the end of each drum is secured an asbestos-lagged brake-ring, this type of brake being



A Novel Hoist.

able to withstand the heat of heavy braking, outlasting a number of sets of wood lagging. One drum is keyed fast and the other runs loose, on a heavy open-hearth steel shaft. Between the drums is mounted the main spur gear, which, as well as the drum, is split in halves, and planed and secured with turned steel bolts driven in reamed holes. The drum is carried on three babbitt-lined pedestals, which are cast solid with the bearings which support the motor shaft, thereby securing a perfect alignment of gears and shafts at all times. The loose drum is driven by means of a jaw-clutch, which is operated by a hand lever on the motor man's platform. On the platform are also mounted the independent hand-brakes of the band type, each brake being able to to hold the load on any point of a 30° slope. All gearing is made of open-hearth cast steel with machine-cut teeth, and all protected by metal guards as shown on the photographs. The bed-plate is of rectangular box-section, being made up of five pieces secured with turned steel bolts. The connections between pedestals and bed-plate are also made by turned steel bolts and dowel-pins. The hoist is sectionalized throughout so that it may be taken through a tunnel 6 ft. square. This hoist is to be placed in a damp chamber, 16 ft. wide and 18 ft. long, with a maximum head room of 8 ft. It is to be operated continuously, or 24 hr. per day, stopping only long enough to reverse between hoists. The position of the cars in the slope is clearly shown by a positive dial-indicator placed in front of the drums.

COMMERCIAL PARAGRAPHS.

FAIRBANKS, MORSE & Co. have moved into permanent offices in the new building at 162 Second Street, San Francisco.

THE HENDRYX CYANIDE MACHINERY Co., 1738 Broadway, Denver, Colorado, recently shipped a complete cyanide plant to the Old Mexico Mining Co., Oaxaca, Mexico.

MERRALLS MILL Co., manufacturing the mining machinery inventions of W. A. Merralls, with headquarters in Denver, Colo., have moved their general headquarters to San Francisco, where they have opened offices at 140 First Street.

CHALMERS & WILLIAMS, INC., have closed a contract for the erection of a complete stamp-mill and cyanide plant, with tube-mill, rapid cyanide filter, and power plant, for Cia. Minera El Conde y Anexas, Tepehuanes, Durango, Mexico.

THE WESTINGHOUSE ELECTRIC & MFG. Co.'s executive offices, now at 111 Broadway, New York, N. Y., and the New York sales offices and export offices of that company, now at 11 Pine Street, will be removed on Monday, April 20, 1908, to the new City Investing Bdg., 165 Broadway, New York.

W. H. KRITZER, superintendent of construction for the Tracy Engineering Co., is now in southern California, erecting a 20-stamp combination amalgamating and concentrating plant for the Orange Blossom Mining & Milling Company.

THE SMOOTH ON MFG. Co. has issued a leaflet describing Smooth-On gaskets. These are manufactured from a specially prepared mild tough steel, with concentric corrugations, and covered with Smooth-On coating, which expands and contracts like iron.

CARROLL HELMICK will have charge of the Salt Lake City office of The Denver Engineering Works Co., of Denver, at 205 Atlas Block. W. L. G. BIGNELL, who has represented them for some time, will open an office for the same company at El Paso, Texas.

THE HENDRIE & BOLTHOFF MFG. & SUPPLY Co. announces that it carries in stock for immediate delivery all standard makes of motors, transformers, generators, and appliances, in all sizes in ordinary use. Its stock of line materials and supplies is the largest west of Chicago, and it can fill any ordinary order without delay. It specializes in the application of electrical power to all forms of machinery, and can furnish from a stock all sizes of electric hoists, electric pumps, electric driven air-compressors and blowers, as well as small lighting plants.

MINE REPORTS.

OROVILLE DREDGING, LTD., OROVILLE, CALIFORNIA.

The Oroville Dredging, Ltd., made up of the Boston & California Dredging Co., Boston & Oroville Mining Co., Oroville Gold Dredging & Exploration Co., Bear River Mining Co., and the Boston Machine Shop Co., operating 12 dredges, in its report issued on April 8, covering the fiscal year ending July 31, 1907, shows total net receipts, after writing off administrative expenses in Boston and London, and paying 10% for the year in four quarterly dividends of 12½c. per share, leaving a surplus balance of $151,842. The total dredging disbursements have been $415,821, and to arrive at the proper cost of operation applicable to this period, there was added to that figure $9725, being the balance chargeable to dredge No. 1 of the Boston & California Co. for a proportion of a new bucket line installed July 1, 1906. This brings up the total to $425,546, being an average of 5.34c. per cubic yard. The gross bullion output was $895,025, or 11.23c. per cu. yd., and the net product from dredging year it dredged out 14.66 acres, to an average depth of 35½ ft. Its average daily duty was 17 hr. 52 min.; average daily yardage, 2943; and total cost per cubic yard, 3.53c. The gravel dredged averaged 6.36c., leaving a net product of 2.83c. per yard. The highest actual daily average duty was by a Bucyrus dredge, which dug 3148 cu. yd from a depth of 29.9 ft., with daily service of 18 hr. 36 min., and an average cost per cubic yard of 3.64 cents.

OROVILLE DREDGING RESULTS.

Property.	No. dredges.	Ground dredged, cu. yd.	Average depth, ft.	Area dredged, acres.	Returns refined, gold.	Averages. Cents per cubic yard.		
						Yield.	Working expenses.	Net Profit.
Boston and California	3	2,010,937	31.4	39.63	$309,397.22	15.38	6.29	8.09
Boston and Oroville	4	2,529,257	27.0	58.04	247,031.61	9.76	5.49	4.27
Oroville and Exploration	3	2,422,146	31.9	47.07	266,812.43	11.02	3.99	7.03
Bear River	2	1,011,338	36.6	18.54	71,783.66	7.10	6.28	0.82
Totals	12	7,973,678	30.3	163.28	$895,024.92	11.23	5.34	5.89

operations was $469,478, or 5.89c. per cu. yd. Other receipts brought up the total profit to $545,827.

Comparing these figures with the previous year, there appears a reduction in operating cost of 0.73c. per cu. yd., and an increase in yardage dredged of approximately 66.7%. The gross yield has fallen off 3.52c. per cu. yd., but this figure is reduced to 2.65c. per cu. yd. when applied against the greater quantity of material excavated and the decrease in the table submitted herewith.

in operating cost. The dredging operations are summarized

Analysis of the items entering into costs and dredge-duty shows the following average for all dredges employed: Daily dredging-time, 17 hr. 54 min.; average daily yardage, 1932; average depth of ground dredged, 30.3 ft.; material and labor, cost per cubic yard, 1.46c.; electricity, 0.71c.; water, 0.09c.; repairs, 2.44c.; general expense, 0.44c.; taxes and insurance, 0.2c.; total, 5.34c. per cu. yd. The total area dredged was 163.28 acres, with the following average results:

Cubic contents per acre	48,834 cu. yd.
Gross output per acre	$5,481.53
Total operating cost per acre	$2,546.67
Net revenue per acre	$2,934.86

Attention is directed to the relative cost per cubic yard of the old type compared with the more modern dredges, which has led the general manager, W. P. Hammon, to recommend retiring three of the old machines. The average cost per cubic yard of the 12 dredges in operating during the year 1906-07, worked out at 5.34c., whereas, if the employment of three of the old type had been discontinued, the total average cost of the other nine dredges would have been only 4.9c. per cu. yd. Mr. Hammon thinks that even the latter figure can be beaten, together with an increase of output, if two modern dredges be installed in place of the three old ones. The best result obtained was by dredge No. 3 of the Oroville Gold Dredging & Exploration Co., working in hard and difficult ground. This machine has buckets of 7-cu. ft. capacity, and is mounted on a hull 100 ft. long, 40 ft. 8 in. wide, and 8 ft. 2 in. deep. This dredge is one of the Boston Machine Shop Co.'s type, and it has been in service since October 20, 1906. The bucket lips are becoming worn, and will need replacing within a few months. During the

TENNESSEE COPPER, POLK COUNTY, TENNESSEE.

The production for the year ending December 31, 1907, from ore out of the company's mines amounted to 12,599,019 lb. fine copper. In addition to this, 205,133 lb. were produced from custom ore. During the first half of the year 2,230,136 lb. of the copper produced were electrolytically refined, and the remainder was marketed in the form of pig copper. There were recovered in addition 14,905 oz. silver and 85 oz. gold, part of which was derived from custom ore. The cost of electrolytic copper, after allowing for gold and silver, was 12.22c. per lb. The cost of producing and marketing per pound of fine copper in pig was as follows:

	Cents.
Cost at works	10.44
Freight, insurance, and other selling expenses	0.68
Taxes, legal and administration expenses	0.67
Total	11.79

The costs per ton of ore mined and treated, on a total output of 389,603 tons, were:

Ore production	$1.1460
Surface transportation	0.1320
Smelting	1.6210
Engineering and laboratory	0.0620
General expense	0.1700
Converting (13,456,519 lb.), per lb.	0.0074

The profits for the year, after deducting $70,000 for depreciation of plant, were $800,634. Dividends of $1.25 and $2 per share, aggregating $650,000, were paid January 28 and August 15, respectively. An additional dividend of $1.25 per share, amounting to $250,000, was paid out of the profits on February 15, 1908. The sulphuric acid plant was completed in December, 1907, and is now producing acid. No revenue was derived from this source during the year 1907.

MINAS PEDRAZZINI, SONORA, MEXICO.

The Minas Pedrazzini Gold & Silver Mining Co., operating in the Arizpe district, Sonora, Mexico, reports for the year ending January 31, 1908, gross earnings of $442,490, and disbursements amounting to $227,407, leaving a net profit of $215,083. Dividends aggregating $170,416 were paid, and undivided profits amounting to $11,534 were carried forward, besides leaving as a special reserve fund $23,667, in addition to the general reserve fund of $21,508. The total output of bullion was 4876 oz. gold and 656,882 oz. silver, from 927 tons shipping ore and 179 tons concentrate.

During the year the company expended in improvements and additions to the plant the sum of $44,222, and performed a total of 3433 ft. of development work, including 191 ft. of shaft sinking. The manager, E. L. Dufourcq, estimates ore reserves at the end of the year amounting to 8900 tons, valued at $859,000.

Editorial.

GOOD NEWS comes from Cananea. We learn that there is a prospect of a general resumption, possibly in June. The smelter is being reconstructed on the latest principles. Among the changes to be made is the substitution of bins at the furnaces instead of direct chutes from the conveyor; in other words, the introduction of a moderate storage of mixed charge at the furnace. The Cananea has had bad luck and poor financing; in its early development it was the victim of frontier metallurgy and Wall Street stock-jobbery, but in the capable hands of A. S. Dwight and later of L. D. Ricketts, this enterprise has been re-organized until it promises to be as economically operated as any copper plant in America.

THE PRESENCE of the great white squadron in San Francisco Bay reminds us that the end in view is pacific opportunity for productive labor, not the shout and din of war. These ships are Uncle Sam's policemen, to prevent some boisterous fellow now and then from disturbing the peace and the even flow of commerce. The glory of war is in the peace that follows victory, as the blessing of a mining camp is in the sane and quiet effort to produce for the world's good, after the swashbucklers have been cowed by the representatives of the law. It is the absence of the policeman that invites trouble, and law-breaking, and murder, and the rest. All honor to our patrolmen of the seas! More ships, gentlemen, for the greater certainty of peace and happy industry! We have the metal in our mines with which to build the ships, and the men in our country to man them worthily.

WE NOTE with pleasure that the prize for the best display of ability as a debater in the University of California was won by a student who took as his subject the evil influence of the bad portion of the American press. After referring to questionable advertising, so-called sporting news, and sensational journalism, he took as his chief theme the sale of news-space and editorial columns to persons or corporations willing to pay for the opportunity to influence public opinion. He referred specifically to the San Francisco *Chronicle*, which received $10,000 from the Home Telephone Company, the purpose of this payment being stated by Mr. Mark L. Gerstle, when testifying before the Grand Jury, to have been "to educate the people to the idea of a competitive telephone system. The *Chronicle* was expected, when the matter came up before the board of supervisors, to write it up favorably." This exposure of corrupt journalism hardly caused a flutter in a community so accustomed to bribery of every kind and inured to a daily press that is a daily insult to the intelli-

gence and refinement of this progressive community. We hope that the students of the University of California will not only debate these questions vigorously, but put their sentiment into action, by refusing either to support or to read newspapers that prostitute journalism.

IT GIVES us pleasure to publish the larger part of a lecture delivered by Mr. J. H. Collins. This lecture was addressed to mining students in London and commemorated Clement Le Neve Foster, formerly professor of mining in the Royal School of Mines. Mr. Collins himself has taken a large and useful part in the development of mining education and belongs to the progressive type of Cornishman of the old school. Although a veteran, Mr. Collins is one of those men who keep young in spirit by maintaining a keen interest in the world about them, being always willing to welcome technical improvement and to encourage the younger men responsible for such improvements. He has the proud satisfaction of knowing that his work will be continued by his own sons, for Henry F. Collins, George E. Collins, and Edgar A. Collins do honor to the stock from which they sprang, as did Arthur L. Collins, the eldest son, who died in the discharge of his duty.

White Lead.

BY WAY of celebrating the arrival of the American fleet in the Bay of San Francisco, we publish an article describing the series of technical processes by which the lead ore of the mine is converted into the white paint on the battleship. We take the reader to Idaho and show him the mine from which the lead ore was extracted, and then guide him mentally through the mill in which the ore is concentrated, to the smelter in which it is reduced, to the plant in which it is refined, and finally to the establishment in which the pure metal is converted into white lead ready for shipment to the Navy Yard. Thus the successive steps are described in detail, the effect being to emphasize the multiplicity of methods required to manufacture a single product and at the same time to link the miner and the sailor, demonstrating that the gleaming white paint comes from the dark places of the underworld and owes its existence to the skill of the men of the pick and gad, of the jig and vanner, of the furnace and refinery. No one who cares to contemplate the intricate series of processes involved in the fabrication of this one product will fail to be impressed by the ingenuity of mechanical device and the science of mining and metallurgical practice whereby the end is attained, suggesting the intricacy of the industrial foundation upon which modern civilization is based.

To the details given in the article itself, we may add that the hulls of naval vessels in commission are supposed to be re-painted at least every nine months, and those out of commission once a year. The approximate cost of painting a ship of the *Connecticut* class is $48,000 for labor and $27,000 for material, making $75,000 in all. It will interest our readers to know that a naval vessel of 16,000 tons displacement will carry 12,000 tons of mild, wrought, and cast steel, also 500 tons of cast and wrought iron, also 200 tons of brass and 100 tons of bronze, besides 80 tons of copper. The lead and bearing-metal will weigh 200 tons; the paint and cement, 150 tons; together with 500 tons of ammunition. And all of this is furnished by the miner and the smelter, so that it is not too much to say that the American navy is the product of the American mine.

The photograph of the first-class armored cruiser *California* illustrates home manufacture, for this vessel was built by the Union Iron Works of San Francisco, as was the famous *Oregon*, which made so spectacular a voyage in order to reach the battle-line. As the *California* rides the quiet waters of the Bay of San Francisco, spick and span in her coat of white paint, the men of this Coast can afford to be proud, for she is the product of native industry. Despite her warlike purpose, this graceful vessel is almost feminine in the beauty of her lines, and to this suggestion is added the decorative and preservative touch of paint, enabling her to glory in the sunshine without fear of blemish, unlike the young women of an ancient day, of whom Martial said:

"The chalked Fabulla fears the pouring rain;
Cerused Sabella dreads the blazing sun."

Fabulla's powder might not be storm-proof, nevertheless, the white lead on the fair Sabella's face was not blackened by sunlight, but by sulphur. The men of Martial's time were evidently no chemists, but they had an eye for the beautiful in nature, assisted by art.

Arrival of the Fleet.

NO ONE who watched the stately procession of battleships filing through the Golden Gate can have helped sharing the patriotic pride of the 800,000 people who waved a welcome from the many hills that look upon the haven of San Francisco. Yet there was a curious absence of noise; the bigness of the amphitheatre made the performers seem small and checked the applause of the onlookers. The size of the harbor of San Francisco was never more emphasized than when the American navy made its evolutions without being cramped for room and the whole countryside was lined with sightseers without being crowded. The immensity of the panorama checked applause, the thousands on the hillsides of the City knew that no shout of welcome could reach the sailors on the ships, so they stood silent, absorbed in the spectacle. The first signal was the faint boom of a gun off the Presidio. The smoke of it joined the low-lying fog that had threatened to mar the glory of the day. Soon the guns of Fort Baker on the Marin shore echoed the welcome, and the smoke almost hid the harbor entrance. Then in silent state the leading battleship glided through the Golden Gate, and at exactly equal intervals of four hundred yards the other gray men-of-war followed, each flanked by a dark torpedo-boat destroyer. The whole of the Atlantic fleet, comprising 18 battleships, advanced in single file, the westerly breeze blowing the smoke of their three-fold funnels ahead of them, so that it mingled with the salutes from

land and water, flinging a murk of battle over the peaceful parade. The clouds hung low across the Contra Costa hills and big shadows darkened the water. Suddenly, as the flagship, the *Connecticut*, approached Alcatraz island and swung southward toward the inner harbor, the light broke through the clouds, the sunshine changed the dull gray hull into a radiant white vessel athrob with insistent life and assertive strength. And as the battleships moved into the sunlit space each of them seemed quickened into life and beauty. While the Atlantic fleet was entering the Bay, the Pacific fleet of 9 cruisers had stood at attention off Angel island, and at the proper moment they took their place in the procession, making an evolution the perfection of which even a landsman could admire. They swung into their allotted order, and thus the whole fleet of 18 battleships and 9 cruisers, with the torpedo-boat destroyers, and auxiliary vessels, came round the point into the anchorage that lies off the water-front of the City. Thus was completed a voyage of 14,000 miles which began on December 16, 1907, and ended on May 6, 1908, after a circumnavigation of the two Americas.

As the American fleet lies at anchor its presence here marks an event of manifold significance. To the business man the $200,000,000 of money represented by those floating arsenals is impressive in a financial way, to the townsman the 25,000 men on board represent a faithful body of defenders, to the patriot the feeling of proud possession in men and vessels is overwhelming. But beyond these obvious suggestions, other thoughts will arise to quicken the imagination. The arrival of this fleet punctuates a historic period; the path of empire has come westward at last, and the commercial importance of the Pacific Coast is conceded. Like Balboa, America stands silent on a peak of prophecy and looks across the waves of the Pacific, ready to fulfill her destiny. History moves fast in these later days. It is barely a century and a quarter since the first ship entered the Golden Gate; that was the *San Carlos*, commanded by Juan de Ayala, who passed through the portal of California on August 5, 1775. Likely enough the Spaniards, in exuberance of spirit, fired the old swivel gun on board the *San Carlos* as a salute to the land of destiny. Thus the Mission of Dolores was founded on the sandy peninsula athwart the estuary of the Sacramento river. The mission of the *padres* belongs to an obliterated era, and yet only three lives separate their day from ours; some of the brave Argonauts who built their cabins near the old Spanish settlement and thus founded the modern San Francisco are even yet alive; so soon is history made; we count time not by the slow beat of the pendulum but by the quick throb of brave hearts. While the cities of the old world have scarcely changed and the highways of commerce across the Atlantic have been kept as of old, here within the space of a century and a half the Spanish dominion has been handed to a new people and from the sand hills washed by the Pacific there has risen a city, the expression of a commerce worthy the protection of a great navy. The San Francisco that rose to greet the squadrons of Admiral Evans was a city that has risen more than once. It is barely two years since disaster swept the seven hills of this City and abased a community of half a million people. No one who saw the crowds hurrying out of the lower town in order to get a spot of vantage from which to see the incoming fleet could fail to be reminded of that other exodus in April 1906. Two years ago today the many acres of broken brick and twisted iron lifted an ashen face to the blue of a pitifully perfect sky; today the same site is covered by splendid structures of steel and stone, traversed by orderly streets, and crowded with eager happy faces. So we of San Francisco give thanks for the arrival of this fleet and for much besides, accepting the event as a token of a happier day when San Francisco, guarded by the national navy, shall look as serenely across the interposing seas to the Orient as to the younger East of her Atlantic ancestry.

"The tumult and the shouting dies." Shall we forget? A people that built such a navy and a community that re-built such a city may well be proud of the outward and visible sign of national and civic life. But shall we not hush our plaudits as we remember the mean and corrupt things done in our midst in the name of business. As nearly a million people stood watching the naval parade, was their subdued demeanor without significance? Despite justifiable national pride and personal pleasure in the event, some of them must have been touched with a deeper feeling; perhaps it seemed that the pomp and circumstance of the splendid procession was but a hollow show unless behind it all stood waiting the purified spirit of a patriotism that is unselfish rather than proud, that is willing to sacrifice personal gain to the maintenance of justice, and prepared to surrender the privilege of the one to the welfare of the many. Can a people be great and strong while yet corrupt and greedy? What is the relation of municipal debauchery to national manhood? Can we industrialize our lives without commercializing our souls? Or is it all a mistake, shall we say business is business, patriotism is sentiment, we must keep the two apart; an individual citizen or a community like ours can be undermined by municipal corruption, filthy politics, and strident incivism, and yet be a part of a national aggregate that shall be white as the hulls of the battleships and strong as the armored walls that guard the aggressive guns? The high steel buildings of San Francisco look down proudly upon the white steel ships at anchorage near-by. May either the buildings or the ships be effective in peace or war regardless of whether the men within them are moved by nobility of purpose or mere lust of life? Is patriotism only pride and civism merely self-assertion? Pardon this bombardment of questions; they are pertinent. We are grown men, not children. The irresponsibility of youth no longer becomes a nation that controls the destiny of the Pacific Ocean, and the reckless fun of a boy no longer befits the City that holds the keys of a national commerce. Let us not forget; let us play our part like men.

Personal.

W. P. HAMMON is at New York.

H. R. WAGNER is here from Mexico.

WILBUR E. SANDERS is at Nevada City, California.

CHAS. O'BRIEN is with the Kodiak Mining Co., in Alaska.

C. A. GREEN, of Mill City, Nevada, is on his way to St. Louis.

FRANK J. BOOTH is at the Republica mines, in Chihuahua, Mexico.

ARTHUR FEUST is manager for the Standard Consolidated at Bodie.

EMMET D. BOYLE will be at Hawthorne, Nevada, for several days.

G. F. ZOFFMAN, recently at Palmarejo, Mexico, is in San Francisco.

R. GILMAN BROWN is expected in London, on his return from Chile.

W. C. PATERSON has returned to Denver from Scotland and London.

EDGAR A. COLLINS crossed from New York to Liverpool on the *Baltic*.

W. A. HEYWOOD sailed from Cape Town on April 8, on his return to London.

E. D. LIDSTONE is superintendent of the Big Four lease at Rawhide, Nevada.

CHARLES S. THOMAS, of Colorado, came to San Francisco from Goldfield, Nevada.

JOHN HAYS HAMMOND has returned to New York from Santa Barbara, California.

R. E. TILDEN has gone to Rawhide, Nevada, to establish permanent headquarters.

RICHARD RUSSELL SMITH is engaged in custom assaying work at Stockton, California.

ROBERT ROBERTSON has returned from South Africa and will reside in San Francisco.

R. S. RAINSFORD has resigned from the A. S. & R. Co. and is now at Jackson, California.

W. H. WEED has returned to New York from a lengthy professional journey in Mexico.

C. M. MACNEILL, D. C. JACKLING, and C. W. WHITLEY, of Salt Lake, are here to see the fleet.

LESTER STRAUSS, who resides at Lima, has been examining mines at Cerro de Pasco, in Peru.

WILLIAM H. FREELAND, manager of the Ducktown smelter, in Tennessee, is here for a brief holiday.

LOUIS JANIN, SR., is engaged in mine examinations at Grass Valley and Nevada City, California.

HORACE W. MUSSEN, of Colingwood, Ontario, is visiting the copper districts of Western America.

GEORGE STARR, manager of the Empire mine at Grass Valley, is spending the week in San Francisco.

L. F. S. HOLLAND has come successfully through an operation for appendicitis. He is at Telluride, Colorado.

HERMAN GARLICHS, for nine years in charge of the lead department of the Perth Amboy smelter, has resigned.

G. M. GOUYARD has returned to New York from Mexico, where he has been spending two months on professional work.

J. H. HARTLEY and his brother, Z. B. HARTLEY, have opened an office as mining engineers at San José, in Costa Rica.

BERNARD MACDONALD, of Guanajuato, has gone to New York for a short visit. His headquarters will be at 35 Wall Street.

W. E. THORNE, on his return from Nevada, has gone to examine some dredging ground in Shasta county, California.

EDMUND D. LACHMAN, formerly with Chas. Butters & Co., is now store manager for the Dolores Mines Co., in Chihuahua, Mexico.

S. E. BRETHERTON now has an office in San Francisco, as a consulting engineer. His son, W. B. BRETHERTON, is associated with him.

W. L. COBB has returned to San Francisco from Wyoming, where he has been examining placer properties in behalf of French capitalists.

PERCY A. BABB, general manager for the Mexican Mines Prospects Development Co., has moved the Mexico City offices to Edificio La Cia. Bancaria, Avenida 5 de Mayo.

FREDERICK HELLMANN, lately general manager of the East Rand Proprietary, is here on a visit to his old home. He will shortly open an office at New York, in partnership with THOS. H. LEGGETT.

General Mining News.

ARIZONA.

COCHISE COUNTY.

A vein rich in silver has been discovered at the Fink property on Silver creek near Paradise.——The Calumet & Arizona is remodeling its assay office, which is situated at the Oliver shaft.

GILA COUNTY.

The fifth furnace of the Old Dominion smelter was blown in yesterday, and the full battery of furnaces is now running day and night, for the first time since the slump in the copper market. When the slump came the old Dominion shut down two furnaces. Last October was the banner month in the history of the Old Dominion smelter. Four million pounds of copper were turned out, the highest record ever made in the Globe district.——Ore running $554 in gold and silver has been discovered in an abandoned mine 75 miles north of Globe, and has caused a rush of miners into that part of the country.——The Warren-Perneson-Moody Co. has struck an immense body of copper ore at its property on Upper Pinto creek. The company is now driving an adit to strike the vein at about 200 ft., from which point a shaft will be sunk.

MOHAVE COUNTY.

The Gold Bug, in the White hills, 30 miles north of Chloride, is being overhauled, after which the shaft will be sunk several hundred feet deeper.——A. L. Darbyshire has purchased the Abe Lincoln group of claims, five miles south of Kingman, and will at once sink a 200-ft. shaft. ——The new shaft on the Last Chance mine of the Goldroad Red Top Co. is now down 20 ft. and is showing good ore. Work on the property will be continued and the shaft sunk to a depth of 100 ft.——Many of the old stockholders of the Blue Ridge Mining Co. have combined and are to bring suit for the recovery of their interest in what is now known as the Tom Reed mines.

YAVAPAI COUNTY.

(Special Correspondence).—The Hull Copper Co. has about 14 ft. of good copper ore in its adit on the Cleopatra claim. It is a heavy sulphide and is identical with the sulphide ore found in the United Verde properties, which are situated just on the other side of a small mountain from the Hull Copper Co. holdings.——The adit which will drain the workings of the United Verde mine will be completed by Aug. 15. The water, now being pumped, is strongly impregnated with copper, which latter is saved by the usual system of precipitation on scrap-iron in tanks and troughs.——The Verde Grande shaft is now down 600 ft. It has entered a soft formation, making progress much easier, and indications are that an orebody will be encountered soon.——The Jerome Mines Development Co., owning the old Harryhansen property, has completed the installation of machinery and has resumed sinking in its three-compartment shaft.——The Sycamore company has suspended operations in its shaft, owing to an excessive flow of water. The ground will be thoroughly prospected, however, and another shaft will be started at once.

Prescott, May. 1.

CALIFORNIA.

HUMBOLDT COUNTY.

The antimony smelter at Bloody canyon, 14 miles from Mill City, was blown in last week for a trial run, and despite the damp weather and wet fuel was a complete success. The furnace is constructed to burn sagebrush.——The Imlay mine, formerly the Morrison, is shipping ore regularly, and reports some new pay-shoots.

INYO COUNTY.

A syndicate of Indiana men has purchased a two-thirds interest in the Red Rose group, near Bishop, and taken a lease and purchase bond on the Ivanhoe and the Gem group of claims. J. E. Wernecke will have charge of the development of these claims.——The hoisting plant for the Bishop Creek Gold Co. arrived last week and will soon be working. ——Rich specimens of ore were found on the Chicago property. A shaft is being sunk.

NEVADA COUNTY.

(Special Correspondence).—The Brunswick is driving an adit to strike the vein on the 600-ft. level.——The Union Hill vein has been struck in a raise from the 250-ft. level at the Union Hill mine. The vein is 18 in. wide and shows excellent ore. The Greek vein, recently struck, is being developed. Cliff Graham is superintendent.——Work has been resumed at the New York-Grass Valley mine by the Prudential G. M. Co., composed of San Francisco people. The company has raised $54,000 to pay off all indebtedness, with a balance in the treasury to carry on development. No money will be expended for surface improvements until sufficient ore has been developed to warrant such a step. The Prudential is issuing one share of its own stock for 20 of New York-Grass Valley. The property was badly mismanaged under the old board of directors and was soon in financial straits. A. P. Wilson has been appointed superintendent.——The 26-ft. raise from the end of the adit at the Jenny Lind has encountered the channel and disclosed large quantities of rich gravel. Drifts and cross-cuts will be driven to determine the extent and strike of the channel. The mill will be started in a few days.—— Work has commenced on the lead-gold ore vein on the Williams-Ryan-Whiting group of claims, near the Mason ranch. A small pump will be installed to handle the water.——A five-year bond on the Bullion mine has been secured by Samuel Mills of this city. The shaft will be unwatered and sunk 500 ft. deeper. The property has been developed to a depth of 1500 ft., with a fair-grade body of ore at the bottom of the shaft. A 2-ft. vein of ore assaying $14 per ton has been struck near the surface on the W. J. Michell ranch. It is probable that it will be worked by the owner.—— Sinking continues at the Central shaft. Excellent ore is being opened up below the 4000 level.——Good ore is being developed in the lower workings of the Pennsylvania. The mill is running steadily.——The Golden Gate M. Co. has purchased the Alpha mine, an adjoining property, which will be worked through the Golden shaft. W. P. Martin is superintendent.——Extensive development work is going on above the 400 level at the Mountaineer mine. A new hoist was recently installed in the adit 900 ft. from the portal. About 30 men are working.——Development work is going on at the Delhi, with considerable ore blocked out. The old board of directors has been re-elected.——Thomas Mulcahy has located the Mammoth claim in the Birchville district.——Work is being prosecuted with renewed vigor at the Champion mines. James Moore has been succeeded by John Stevens as foreman.——The Murchie shaft is going down steadily. Good ore is coming from the lower levels and developments are under way.——At the Yuba mine, in the Washington district, arrangements are being made to operate the property on an enlarged scale during the summer. A large force of men will be employed.——Work on several of the copper properties in the French Corral district is expected to be resumed at an early date.

Grass Valley, May 7.

PLACER COUNTY.

Nickey & Beers have started work on their Standard Unit property.——Twenty men are at work at the Hidden Treasure.——The Ray & Savage mine on Duncan ridge will start at once driving an adit.——The adit at the Clark mine on Devils canyon will be extended 500 ft. farther, with the hope of striking the Dardanelles channel.——The old Bishop mine, now called the Pacific, has been bonded to Oakland capitalists.——The owners of the Rueblin mine will enlarge their stamp mill this season.——Ed Cavanaugh has sold one-half of his interest in the Black Canyon, one mile and a half above Westville, and work on the adit will be resumed.——Vore and Young have stopped sluicing at the Annie Laurie because of lack of water, and are driving cross-cuts from the head of the adit.——The Long Valley Mines Co. has been incorporated with the purpose of acquiring and working the Hafner quartz mine, on Rush

creek.——The Bonnie placer on Poorman's creek will be worked.

SHASTA COUNTY.

The Colorado, two miles south of Shasta, has been bonded to N. W. Kleyn-Schoorell of Mill Valley, who will proceed at once with development.——The hull of the new suction gold dredge, built at Central Spur, has been launched and the machinery will be put in at once.——Furnace No. 2 at Kennett will be ready to blow in about May 10, after which furnace No. 1 will be given an overhauling.

SIERRA COUNTY.

A rich shoot of ore has been discovered in the Ophir mine at Alleghany.——The Sierra Buttes, one of the oldest quartz mines in California, is being reopened.——A free-gold quartz vein about 16 ft. wide was opened in the Young America at Forest City last week.——Forty men are working at the Bellevue mine, between Gibsonville and La Porte.

TUOLUMNE COUNTY.

A new pipe-line is being put in at the Little Bonanza mine at Sonora, and when it is completed the mine will start again.——The Wild Cat and Joe Hooker properties, at Soulsbyville, are being unwatered, preparatory to working. ——The Gilt Edge placer mine, near Confidence, is working. ——The Arbona, at Tuttletown, mine and mill are running full blast. New machinery has recently been put in.

TRINITY COUNTY.

The Lappin mine has started up again with a force of seven men.——At the Brown Bear mine six leases are being worked, employing 20 men. The mill is running steadily on ore from the different leases.——The Bullychoop is working 30 men, and the mill will start soon. A 1300-ft. gravity tram from adit No. 7 to the mill has been completed.——The Globe mine, near Dedrick, will soon be opened and equipped with new crushing machinery.—— The Nash mine, on Coffee creek, has been leased to Gordon Abrams of San Francisco, who put 30 men at work.——The Golden Jubilee mill will start soon.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Black Eagle mine on Chicago Mtn. is shipping a heavy tonnage of smelting ore. Recently the 15-ton mill, situated near the base of the mountain, was remodeled, the capacity being increased to 40 tons per day. Only ore carrying less than $12 per ton is being treated, the balance being shipped direct to the smelters in Denver. Operations are being centred on the 4th and 6th levels, where large reserves of mineral are in evidence. An aerial tramway has been constructed from the collar of the shaft to permit of handling the ore at less cost.——The Merry Monarch adit on Fall river is being driven steadily forward, having been advanced 100 ft. The heading is now penetrating the network of veins traversing that district.——A contract has been awarded by E. M. Moscript, owner of the Lone Tree mine in the Lamartine district, for driving the Teller adit to intersect the Lone Tree vein. According to surveys, the objective should be reached within 75 ft.——A. Thoman, leasing on the Gold Dirt, is carrying a stope upon an 18-in. streak of gold-bearing ore. Regular weekly shipments are being made, with average returns of 5.6 oz. gold per ton. Jacobs & Horstman, leasing on the 5th level of the same mine, are breaking 5-oz. gold ore, and in addition a big body of mill dirt is exposed.——Chas. Carlson, leasing on the Lucky Hesperus, Democrat Mtn., is running a drift on a 6-in. streak of 800-oz. silver ore. Stoping is to be started shortly. ——The Butts lease on the Astor is making an excellent showing. A body of quartz mixed with ore is showing in the stope, that is from 2 to 2½ ft. wide, and from recent shipments returns of 250 oz. silver per ton have been received.——The Capital mines are breaking all records, from a production standpoint, in the Georgetown district. During the past week 50 tons of concentrate were marketed that brought $300 per ton in gold, silver, and copper. This mill is now treating 135 tons of ore daily.——The Lorenza mine, on Saxon Mtn., is again undergoing development. The adit is now in 300 ft. and a big body of mineralized quartz is showing which is heavily seamed with stringers of high-grade ore. Green carbonates are showing and assay tests show values of 1000 oz. silver per ton. Albert Santo is the owner.——The Dunkirk, on Sherman Mtn., is being developed by a syndicate of Denver capitalists. A raise is being carried from the Ashby adit level and a body of lead-zinc ore 18 in. to 2 ft. wide is being followed. The product is to receive separation at the Mendota mill.—— The Horseman property, in the Daily district, is being developed. The adit is in 300 ft. From the shaft workings a fair production was made a number of years ago. ——A raise has been started on the Ramsdell, which is destined to connect with the old shaft workings, down to a depth of 70 ft. There is exposed a 4-in. streak of $60 gold and silver bearing ore. From the old workings a production of $25,000 was made a few years ago.——The strike made a few weeks ago on the Ocean Wave tunnel of the Colorado Central is growing richer. The vein measures a full 18 in. wide and the last mill-run brought over 1000 oz. silver per ton. This is the richest block of ground operated in the mine in over 10 years, and a record-breaking production is being made. F. A. Maxwell is the lessee.—— The Mineral Chief mill will be completed by June 1.—— The New Boston mine, on Democrat Mtn., has entered the list of shippers and from this time forward a steady output is promised.——The compressor plants at the Tobin and Wilcox adits were started May 1. As a result the lessees are again at work breaking ore, and shipments will be started next week over the Argentine Central.——Work is to be resumed on the Josephine, West Argentine district. Previous to the close-down for the winter a streak of ore had been encountered in the raise 900 ft. from the adit entrance, that measures from 8 to 12 in. wide, carrying $60 per ton in silver and lead. Shipments will be started at an early date.——The Montgomery-Ward adit, Republican Mtn., is being driven steadily forward. A number of stringers of ore have been encountered, and it is believed that the Pay Rock Extension vein has been reached. From ground in close proximity a production of $3,000,000 was made a number of years ago from the old Pay Rock mine. ——It is reported that work will soon be resumed on the P. T. mine, situated on Chicago Mtn. The water in the shaft workings has been drained by the Quito, and the reserves of medium and low-grade ore can now be handled. Denver capitalists are interested in the enterprise.——The Quito shaft is being sunk by day labor, an average of 4½ ft. per day being made.——An 8-in. streak of solid lead ore has been encountered in the raise being carried from the Teller adit to connect with the Freeland workings. This raise will be completed within a few days, at which time natural ventilation will be afforded.——The St. Louis shaft on the Crown Syndicate holdings, Lamartine district, is to be sunk 400 ft. farther, making the total depth 700 ft. Buildings are to be erected and necessary machinery installed at an early date.

Georgetown, May 5.

LAKE COUNTY.

Operations were started last week on the Louise property, in South Evans gulch. Otto Thurn, who has a lease, expects to sink the shaft 100 ft. deeper and then prospect. It is possible that the present steam plant may be replaced by electricity.——New machinery is being placed in the Canterbury mine, which will soon be worked in connection with the Catawaba and other mines in the Canterbury district.——Sixty tons per day of iron ore are being shipped from the upper levels of the Starr. The shaft is being retimbered and the lower levels will be worked later.——The Anona, on Long and Derry hill, opened last week, working 30 men in three shifts. Since the mine was closed in November electricity has been installed for both power and lighting. The shaft is down 90 ft., from which level the work will be done at present.

OURAY COUNTY.

A good strike was made lately on the Snow Flake, at

Red Mtn. The orebody is a large one, and is in two grades, one averaging $45 and the other $52.——M. T. Chestnut, Jr., has purchased an interest in the Killarney claim.——A vein carrying gold, silver, copper, and lead has been struck in the adit of the Precious Metals property near Chattanooga.

TELLER COUNTY.

The Isabella Co. shipped three cars of low-grade ore from their Bull Hill property last week.——The Calhoun Investment Co. has purchased the Cog Road, Last Shot, and Peak View claims.——James Hoar has leased the Alice property on Raven hill.

The Joe Dandy cyanide mill has been remodeled, and is running again, with double the former force. The shaft on the Joe Dandy is down 500 ft. and laterals have been extended on every level.——The bottom level of the Requa Savage has been connected with the shaft on the Home claim, and as a result the ventilation in the former is much improved.——H. J. Austie has leased the E. Porter Gold King property, on Gold hill, for a term of two years on graded royalties.——King Bros. have taken a sub-lease on the dump of the Abe Lincoln and expect to ship one car per day.——The Wabash Con. M. Co. has purchased the Colorado and the Bear Valley placer claims.

IDAHO.

IDAHO COUNTY.

(Special Correspondence).—Native gold has been struck in a newly opened property in the Clearwater valley, about 14 miles from this place. The gold was found at a depth of 50 ft. by John Howard and John Lackey, who have been working a claim since last fall. Many locations have already been made on top of the snow, and some conservative mining men believe it means an important stimulus to the gold production of this district.——The Sacajawea Exploitation Co. has put some new machinery on the claims formerly known as the Old Montana group, and is preparing for a summer's run. The equipment consists of two giants and a line of 22-in. pipe.

Orogrande, May 1.

(Special Correspondence).—The Buster mine is carrying on development at the 400-ft. level, and preparing to add 10 stamps to its present mill. The mill is running night and day.——The Espy property is being equipped with a five-stamp mill. Several carloads of the ore sent to the Tacoma smelter for treatment have given net returns of $225 per ton after being transported by pack-horse and freight-wagon a distance of 33 miles.——A 10-stamp mill is now running near Newsome, and a dredge has been installed to work the gravel of Newsome creek. As soon as the snow is gone several giants will be put to work washing gravel. ——The Hogan mine is now preparing for a season's run after being shut down two years. The 20-stamp mill is being overhauled and repaired and a crew of 35 men is at work.——The Twin Buttes property is ready for operation with a plant consisting of rolls and crushers instead of stamps.——The Umatilla is putting its 10-stamp mill in readiness for work. The company owning the property is also constructing a power plant on the Clearwater river which is expected to be finished this summer and will cost $100,000.——The Thunder Mountain people have just installed a new 60-hp. boiler, increasing their capacity to 90 hp. A 10-stamp mill is also being operated on the property day and night. Recently a 9-ft. vein was opened up in the lower workings, and tests have shown it to be of unusually high grade.

Elk City, May 4.

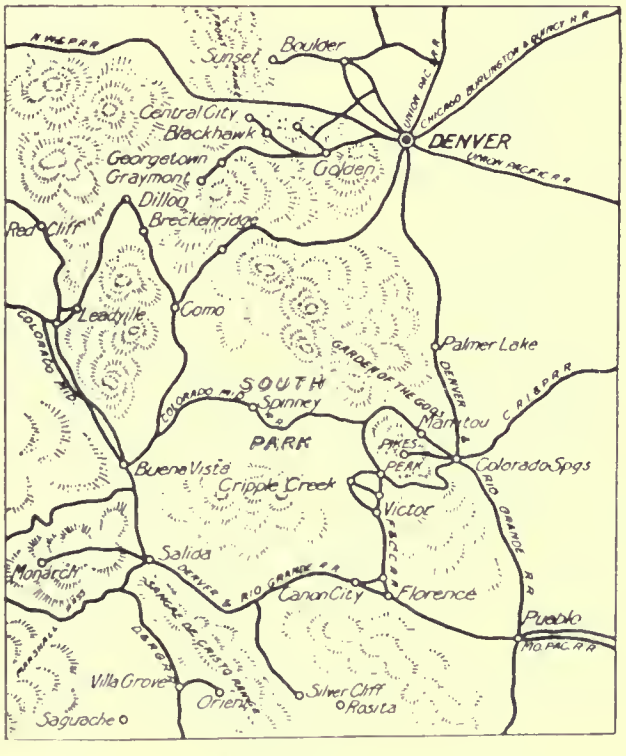
NEZ PERCE COUNTY.

(Special Correspondence).—The Idaho Co. is now operating its 3¼ Risdon dredge here, employing a crew of 12 men. It is the intention of the management to bring over a similar machine from Delta, which was bought and dismantled last year, and install it on the grounds now being worked. Some new land has been purchased during the winter, which, added to that already owned, gives a field that it is estimated will last a dozen years with the two dredges at work. The gravels of this district are very rich in gold, but the Idaho Co. does not disclose any returns.—— The Ozark Mining Co. recently made a valuable strike in a cross-cut in its main adit about 100 ft. from the portal. The ore is free-milling gold. Work, however, is to be pushed on the adit, and no serious attempt to explore the workings will be made until the lode is tapped, several hundred feet ahead of the present face. This adit was begun last winter, and engages two shifts. An 8-drill air-compressor has been installed and is now in use. The property is considered rich, and gives evidence of several small veins intervening between the portal and the main vein.——The Tacoma Business Men's Association has the largest pump ever brought into the Orofino creek workings, and additional machinery is being set up. The association owns extensive deposits of rich gold-bearing gravel.

Pierce, May 1.

OWYHEE COUNTY.

Work has been resumed on the new Potosi mill. The grading is nearly completed, the machinery is all purchased, and mill erection will start this week.——The



A Part of Colorado.

Village Blacksmith reports the discovery of a thin but very rich vein.——The mill at the Banner is nearly completed.

SHOSHONE COUNTY.

(Special Correspondence).—The Success mine has taken a bond on the Monitor mine, situated across the line in Montana, for $150,000. The Monitor has produced about $150,000 of ore during several years of operations. It is opened by a shaft 400 ft. deep and by numerous drifts and raises. According to the terms of the bond, the shaft must be sunk 300 ft. farther, and $60,000 expended in development.——The Rex mill is treating 100 tons of ore daily. Development is also being carried on, and some new machinery is being put into use in sinking to lower levels. ——The Charles Dickens mill, on Moon creek, will soon be running again, the last machinery having been delivered to the site. Last January fire destroyed the plant, and mining operations have been interrupted since to a great degree. The work of development, however, has been carried on, and a cross-cut is now being run in No. 3 tunnel, which is thought to be but a few feet from a large ore-shoot, which will be tapped at a depth of 575 ft. The new plant will have a capacity of 200 tons daily.

Wallace, May 1.

NEVADA.

ESMERALDA COUNTY.

The work of grading for the Rawhide Western, the new railroad from Modoc to Rawhide, was started last week.——The report of a number of rich strikes 18 miles south of Rawhide has caused a rush, and the new camp of Bovard is the result. The surface showings are reported rich in free gold.——A new strike on the Tuett lease, at Rawhide, is reported to be rich in gold and silver.——The Horseshoe, at Goldfield, will resume work at once.——The St. Ives, the Velvet, the Potlatch, and the Gold Horn properties, comprising 117 acres east of the Goldfield Consolidated, have been merged under the name of Goldfield Merger Mines Co., capitalized for $5,000,000. The new company will start at once the sinking of a three-compartment shaft 1000 ft. deep.——The new electric pump at the bottom of the 500-ft. incline shaft on the Kewanas, will be ready for work soon.——The total shipments from Goldfield for the week ending May 2 were 1682 tons, valued at $114,400. The shipments from the Tonopah mines for the week were as follows: Tonopah Mining Co., 2300 tons; Tonopah-Belmont, 580; Montana-Tonopah, 1100; Jim Butler, 240; Midway, 400; West End, 60; MacNamara, 153; Tonopah Extension, 230. Total, 5063 tons.

HUMBOLDT COUNTY.

The Buckhorn and Buckhorn Fraction claims have been sold to N. A. Brown of New York.——Incorporation papers of the Golconda Leasing & Mining Co. have been filed. This company will take over and operate the Butts & Oswald lease on Kraimer hill, two miles south of Golconda. A 25-hp. hoist has been shipped from Salt Lake City and will be installed at once. A shaft has been sunk on the vein to a depth of 75 ft. High-grade ore was sacked at the surface, and from cross-cuts at 30, 60, and 75 ft. Four feet of the vein at 75 ft. assayed $61 per ton, while 18 ft. of the adjacent quartzite assayed $9 per ton. Twenty-two feet of ore has been cross-cut and no walls reached. A 10-stamp mill will be placed on the property within a few months.——The Kindergarten mill, at Seven Troughs, is nearing completion and will begin operations in ten days.——The water has been pumped out of the 100-ft. winze from the lower tunnel of the Mazuma Hills mine and milling ore is being blocked out on three levels. In addition a road is being built to the mill along the hill north of Mazuma.——At the Kindergarten a track is being laid on the 150-ft. level to the Wihuja incline shaft in the Therein property. The Wihuja skip is to be used to elevate the Kindergarten ores to the surface until the Kindergarten working shaft is completed.——The hoisting plant for the Bard & Jess lease has been shipped from Denver. The shaft is now down 165 feet.

LINCOLN COUNTY.

A vein rich in silver has been struck in the Day mine at Jack Rabbit.——The Boston & Pioche has ordered a 100-hp. gasoline engine and compressor, both of which will be used at the Ynba East.——The Ohio-Kentucky will put in new compressors and drills on both the Susan Duster and Prince properties.——The main shaft on the Lucky Dutchman at Crescent is down 325 ft., 850 ft. of drifts are completed, and shipments will soon be resumed.——The Big Tiger will erect a small stamp-mill to handle the accumulation of low-grade ore.——At the Roderick group a shaft is being sunk and heavily timbered in anticipation of deep work.——The Red Star Co. expects to start sinking a shaft on its property at Crescent, and will also probably lease several large blocks of holdings.——The Chief of the Hills claim is now sending ore believed to be high grade, to the Quartette mill.——The Duplex has cut the New Year's Gift vein in the north cross-cut extending from the 500-ft. level of the Fraction claim.——The Goode Hope mine will soon be equipped with a 50-ton mill.

WASHINGTON.

STEVENS COUNTY.

(Special Correspondence).—The Morning-Mammoth Concentrator Co. has just let a contract to the Hallidie Machinery Co. for the erection of a 200-ton concentrator at Metaline, which is to be in operation by October. The plant will cost $50,000. The Morning and Mammoth mines, owned by the same people, are being developed and already have a sufficient quantity of ore in sight to keep the mill going.——The Oriole mine is extending its adit from the 300-ft. station to tap a second vein at 50 ft. distance. In a drift 80 ft. from the adit sulphides of silver were recently discovered.——The concentrator of the Spokane Lead Mines Co. at Metaline is being pushed to completion, and will be ready for ores in May.

Metaline, May 2.

CANADA.

BRITISH COLUMBIA.

The Silver Cup mine, near Revelstoke, made last month the largest shipment of ore in the history of the mine. The ore averages 150 oz. silver, ¾ oz. gold, and 40% lead.——A ton of ore, reported to be worth $18,000, was recently stolen from the Klaskino Mining Co.——Two shifts are now regularly employed at the Gold Drop.——A 10-stamp mill will be erected at the Little Bertha, 16 miles above Grand Forks.——The Granby Con. Co. shipped 264,581 tons of ore from its mines to its smelter during the first three months of 1908, producing 6,600,000 lb. blister copper. During the corresponding period last year 130,483 tons were shipped, producing 3,250,000 lb. blister copper. Last year the company earned $500,000 net during this period, but with the increased output this year the profit was only $150,000.

Following is the tonnage of ore shipments from and crushed at the mines of Rossland for the week ending April 25, and for the year to the same date:

Mine.	Week.	Year.
Centre Star	3,540	56,558
Le Roi	1,295	27,829
Le Roi No. 2	210	9,775
Red Eagle	20	20
Evening Star	....	428
Blue Bird	....	60
California-Giant	....	60
Totals	5,065	94,200

There was received during the past week at the smelter of the Consolidated Co. at Trail 4725 tons of ore. Besides that from the Rossland camp, shipments were received from other mines as follows: First Thought, 145 tons; Snowstorm, 528; Nancy Helen, 31; St. Eugene, 233; Standard, 86; Whitewater, 23; North Star, 139; Millie Mack, 102; Rambler-Cariboo, 102; Ruby, 43; True Fissue, 12 tons.

A switch has been put in at the Homestake for the accommodation of the Blue Bird, and shipments are to be made regularly.——Quayle, Goldsworthy & Jewell have leased the Curlew claim in the south belt for one year and will begin work at once. The Curlew lies immediately south of the Blue Bird.

MEXICO.

It is stated that the Mexican Mines-Prospects Development Co., Ltd., of Mexico City has obtained control of two groups of properties in Jalisco, the San Luis del Oro group of 82 pertenencias in the Hostotipaquillo district, and the Juanquiniquila group of 131 pertenencias situated 30 km. to the southwest of San Marcos. There are several well defined veins from 3 to 8 m. wide in each of the two groups. The San Luis del Oro properties are silver-gold, while the Juanquiniquila are copper-gold, and some shipping ore is now being extracted from this latter group. Both the groups, however, are still in the prospect stage and will be systematically developed.——The Casados mines, in the Hostotipaquillo district, have been unwatered and developed with satisfactory returns. This property is under the control of the Consolidated Mining Co.——The Granadena Mining Co. is constructing an aerial tram from the mill to the Mexican Central railroad station at Santa Barbara, a distance of about 5 km., or a little over three miles. This tram is to have a capacity of 10 tons per hour, and its erection will be pushed with the utmost speed. The mill will resume work in about 60 days, and everything is being put in first-class shape for a big production.

Special Correspondence.

LONDON.

Australian Companies' Reports.—Golden Horseshoe.—Ivanhoe.—Perseverance.—Dry-Crushing and Roasting Gold Ore.

The reports of three of the big Australian companies, the Golden Horseshoe, the Ivanhoe, and the Great Boulder Perseverance, have been issued this week. They afford several subjects for study and discussion, of which perhaps the most interesting is the method of paying for equipment out of revenue, but the information as to costs and management is also of importance. During 1907, the Golden Horseshoe sent 246,775 long tons of ore to the stamps, which caught 38,784 oz. of fine gold. In the sand-treatment plant, 24,716 tons were cyanided and yielded 6535 fine ounces Of slime 208,693 tons produced 56,967 oz., and 13,506 tons of concentrate produced 35,879 oz. In addition, 30,479 tons of old sand and slime, which was re-treated, produced 8528 oz. A parcel of 245 tons of ore was shipped to the smelters, producing 310 oz., as also was cyanide slag containing 775 oz. The total production of gold was 147,680 oz. The total cost per ton, including development, shaft-sinking, and re-treatment of tailing, amounted to £1 5s. 6d., as against £1 8s. 10d. during 1906. The extraction, not counting the re-treatment of tailing, was 86½%, and the average value recovered, £2 10s. 11d. The mine is continuing to open up in a most satisfactory way, and managers, directors, and shareholders have no worries or anxieties. The main shaft is now down to the 1650-ft. level. The ore reserves are figured at 1,062,332 tons, estimated to contain 650,608 fine ounces, sufficient to keep the mill at work for over four years.

The Golden Horseshoe Co. was originally formed in 1894 and commenced to make profits in 1898. The first dividend was paid on Jan. 14, 1899, amounting to £75,000, and the second, third, fourth, and fifth, of equal amounts, were distributed during the same year, bringing the first year's distribution to £375,000. Those were the days of rich ores and bonanzas. Subsequently the mine settled down to economic mining, and the yearly distribution has been between £250,000 and £300,000. For the year 1907 the amount was £255,000, and the total distribution to date £2,520,000. The nominal capital of the company is £1,500,000, having been increased from £300,000 in 1899, by altering the denomination of the shares from £1 to £5. This alteration was made so as to bring the nominal value near the real value, or at least nearer the market quotation. Different counsels ruled in those days of booms, and the policy of keeping down fixed charges was inaugurated later on, when mining was conducted as a more legitimate business. The policy has been not to capitalize equipment, but to make the mine pay for all expenditure. Altogether £440,000 has been spent on plant, and £267,679 on mine development. The whole of this expenditure has been met out of revenue, and the items of mine development and plant machinery and buildings do not appear in the balance sheet. The general manager of the mine is John W. Sutherland, and the company belongs to the 'Kaufman group.'

The second company mentioned, the Ivanhoe, may be called a 'Govett company.' The general manager is R. B. Nicholson, and Bewick, Moreing & Co. are the consulting engineers. The mine adjoins the Golden Horseshoe and the Great Boulder Proprietary, and was floated in 1897 by Whitaker Wright. The capital is £1,000,000 in £5 shares. As in the case of the Horseshoe, the expenditure on development and plant has been charged to revenue. Altogether £740,313 has been spent in this way, and all this has been written off except £54,295, which represents the original working capital in hand when the company was formed. During 1907, the stamps crushed 231,050 short tons, and produced gold valued at £151,143. Of sand 111,514 tons yielded gold worth £82,969, and 99,811 tons of slime produced gold worth £160,379. In addition, 19,725 tons of concentrate yielded £128,078. The total extraction of gold had a value of £522,571. The ore was estimated to be worth £2 12s. 0d. per ton. Of this £2 5s. 3d. was extracted, being at the rate of 87%. The working costs were £206,209, and mine development and plant £47,884. After paying London expenses, etc., a net profit of £261,378 was made, and £240,000 was distributed as dividends. The ore reserves are calculated at 926,737 tons, estimated to contain gold worth £2 12s. 0d. Since the commencement the company has taken out a total of 1,075,559 fine ounces of gold, valued at £4,584,045. The dividends up to the end of 1907 sum up £1,940,000.

The Great Boulder Perseverance reflects even more credit upon its managers than the two companies already referred to, for its position has been retrieved after sinking deep in the mire of mismanagement. Of course most of the West Australian companies were extravagantly managed in their early days, both as regards prodigality of expenditure and careless or willful exhaustion of the best ores. The Perseverance had a very bad fall, and the problem that the new controllers and engineers had to face was a difficult one. The largest share of the credit belongs to Edward Hooper, who took the position of consulting engineer at the darkest hour. The figures for 1907 give an excellent idea as to how the mine stands now. The method of treatment is by dry-crushing in Griffin mills, roasting, fine-grinding, and filter-pressing. During 1907 the amount treated in this way was 199,958 short tons, and the recovery of gold was 80,927 fine ounces, realizing £344,131. The average grade of ore treated was 8½ dwt., and the recovery just over 8 dwt. The amount treated was 30,764 tons more than in the previous year, an increase due to the provision of additional crushing plant. At the same time the average grade of the ore decreased from 10¼ dwt. to the figure above mentioned. After paying working expenses, the cost of development, and allowing for depreciation, a net profit was made of £96,843. Out of this, dividends absorbing £69,972 have been paid, which is 5% on the nominal capital of the company. The finances of the company are in good shape, for the plant, equipment, and development account stands at only £26,435 on the balance sheet. The high figure of the nominal capital, £1,399,459, is a relic of previous days, and it makes the rate of dividend look small. Another relic of the same sort is the appearance of a loan of £49,470 to Frank Gardner as an asset in the balance sheet. No doubt the directors hope to realize this some day, or they would have written it off. It will be remembered that Mr. Gardner used to be the controller, and this loan looks a little irregular. To be quite just to Mr. Gardner it should be mentioned that in the early days of the company he provided large sums of working capital, which were afterward repaid out of profits at a time when money was not easily obtained. As regards the present outlook, the ore reserves are figured at 461,598 tons containing 7½ dwt., as well as 161,597 tons of probable ore. During the last few years the amount of exploration and development work has been large, and the engineers now consider that the ground is so well known that the expenditure in this direction will be much less in future.

BISBEE, ARIZONA.

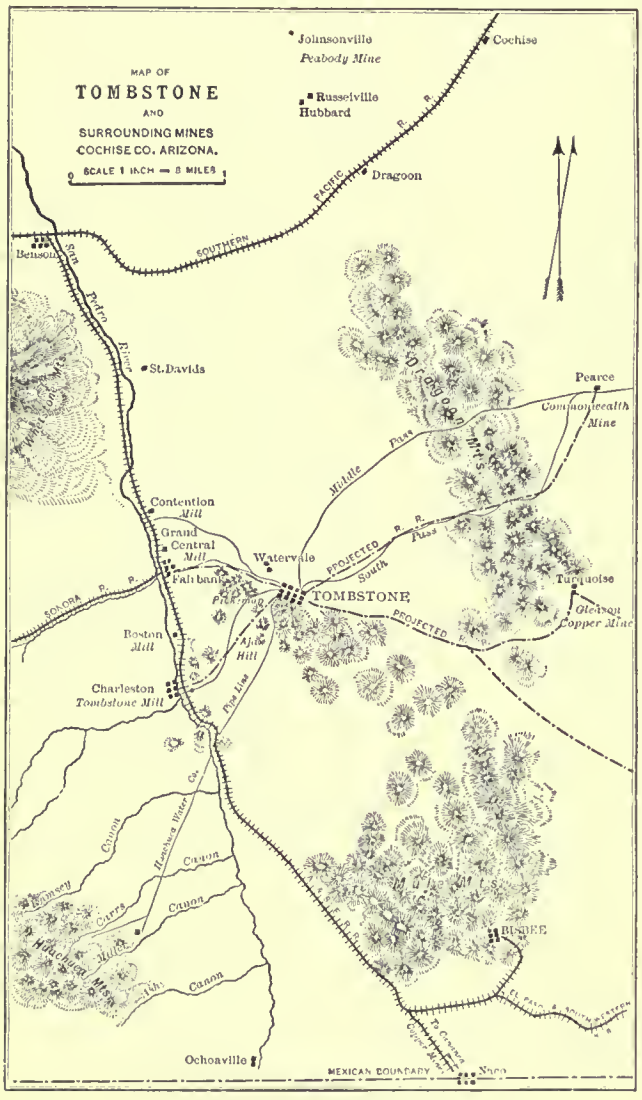
Copper Queen.—Electric Haulage.—Concentrating Traffic in Sacramento Shaft.—New Orebodies Found.—Calumet & Arizona.—Superior & Pittsburg.

Although the ore production in the Copper Queen is still slightly below what it was during the times of greatest activity, a normal number of men are employed, and a large amount of prospect and improvement work is being done. The most important piece of underground improvement being carried on is the preparation for the new electric haulage system. This will be in operation as soon as the necessary underground and surface work can be completed. Instead of hoisting the ore as at present through five different shafts, it will all be raised from one shaft, the Sacramento. The haulage drifts are on every other level, beginning at the 400-ft. From the Gardner to the Sacramento the drifts are on the 400, 600, 800, and 1000-ft

levels, and from the Lowell to the Sacramento on the 1000 and 1200-ft. levels. The drifts from the Gardner are completed; those leading to the Gardner from the older shafts are now being widened, and made higher where necessary; while the Lowell drifts are not completed as yet but are being driven ahead as rapidly as possible.

The Lowell shaft is now being sunk from the 1300 to the 1400-ft. level and has reached a depth of 1350 ft. From the 1400-ft. level drifts will probably be pushed at once toward the Hoatsou side-line so that ground on the Queen side of the dividing line can be prospected. This territory is already proved to a large extent by the excellent ore developments on the Hoatson 1200-ft. level, which is about 20 ft. below what will be the Lowell 1400-ft. level.

During the past few months the Copper Queen management has been devoting more than the usual amount of



Southeastern Arizona.

attention to the development of its unexplored property, paying particular attention to the country south of the Dividend fault, which cuts off the ore-bearing limestones from the barren Pinal schist in the northern part of the property. This prospect work has brought to light several new orebodies of promise, the most important recent discovery being a large body of sulphides lying between the Holbrook shaft and the fault on the 500-ft. level. The drift in which this discovery was made has already passed for some distance through good ore, and a cross-cut has shown the orebody to be of considerable width as well. Ore has previously been encountered in this section of the mines on the levels above, but there has been no evidence to show that it extended to this depth. Work is still going on to ascertain the actual dimensions of the orebody, and on the assumption that it extends downward for at least 100 ft., one of the main drifts on the 600-ft. level is being pushed out to this section of the mine. In the southwestern part of the property, on the Uncle Sam claim, which is bounded on the southeast by the Shattuck property, a new shaft has been sunk to a depth of over 400 ft. and is still being carried down at the rate of about 100 ft. per month. As yet no ore has been found in this region, although at about 350 ft. the shaft passed through one of the numerous porphyry dikes which penetrate the limestone, and which in many instances have been found closely associated with good ore. Recently some good oxide ore was found in one of these porphyry dikes near the limestone contact on the 200-ft. level in one of the cuprite drifts. This orebody has not as yet assumed dimensions of importance, but it is considered a good prospect, and a winze has just been started to follow it in depth.

There are still a large number of unemployed men in camp, but less than two months or so ago. A few new men are put on at the mines each day, but merely to take the places of those leaving, without any increase in the force.

At the Calumet & Arizona during the past few months particular attention has been paid to blocking out the ore, so that with no new discoveries the present production could be maintained for a long period of time. In the Oliver, on the 1250-ft. level, large bodies of high-grade sulphide ore have been recently opened. Within two weeks there has been a good body of oxide ore opened up about 1000 ft. southwest of the shaft, in entirely new country. Prospect work which has recently been started on the 1250-ft. level of the Irish Mag has not as yet resulted in the discovery of any ore. At Douglas the Calumet & Arizona smelter is handling as large a tonnage as ever before in its history, the average being a little over 1500 tons daily. Of this, nearly 800 tons is from the Calumet & Arizona mines and the remainder from the Superior & Pittsburg.

The Junction shaft of the Superior & Pittsburg, in spite of the heavy flow of water, was successfully sunk from the 1200 to the 1400-ft. level. On the 1300-ft. level the pumps are installed and driving has proceeded several hundred feet from the station, with no ore developed as yet. On the 1400-ft. level the station is not completed. The pumps on the 1000, 1200, and 1300-ft. levels are now handling 3600 gal. per min., which includes water from the Hoatson workings. No oxide ore is now being shipped from the 900 and 770-ft. levels, but a small quantity of high-grade sulphide ore is being mined on the 1200. The Hoatson shaft is shipping about 300 tons per day, almost entirely from the stopes on the 1200-ft. level. These stopes contain both oxide and sulphide ore of high grade and extend about 300 ft. along the west side-line of the Del Norte claim, which borders on the Copper Queen property. Development work on the 1300-ft. level is being pushed ahead rapidly; toward the north end of the claim a few seams of chalcopyrite have been encountered, and in the centre of the claim, 200 ft. south of the shaft, oxide ore of fair grade has been found, which, taken with the location of the ore and the dip of the limestone on the 1200-ft., promises well for the future of this level. No work will be done at the Briggs shaft until cross-cuts from the Junction drain the surrounding territory sufficiently to allow sinking without great expense.

The Cole shaft is producing about 300 tons of oxide ore per day, principally from the old stopes. The two new orebodies discovered within the past four months are yielding a considerable quantity of high-grade ore. These orebodies are between the Cole shaft and the Oliver of the Calumet & Arizona.

The Shattuck-Arizona Co. at present has about 25 men employed, all engaged in development work on the 600, 700, and 800-ft. levels. About the same number of men have been employed since the mine stopped shipping ore in November. Most of the work has been in new territory, and the results have been satisfactory to the management. The bids on the smelter are all expected to be in this week and will be sent at once to the directors in Duluth. At the Denn-Arizona the third diamond-drill hole is being sunk from the 1100-ft. level. Aside from this nothing is being done.

SEARCHLIGHT, NEVADA.

Hart, California.—Active Development.—Water-Works Installed.—Jumbo Shaft Being Sunk by Quartette Co.—Big Chief Adit.—Development in Signal District, Arizona.

The Hart district occupies the southern portion of the detached Piute range of hills, 25 miles west of the Colorado river, situated mostly in San Bernardino county, California. The town of Hart is at the base of this range, 25 miles south of Searchlight, Nevada, and is three miles from Hitt station on the Santa Fe branch that extends from Barnwell to Searchlight. Stages and automobiles meet all trains at Hitt, and an automobile line has been established between Searchlight and Hart. The town is supplied with water by pipe-line, through which it is pumped from wells at Barnwell. This was put in by the Rock Springs Cattle Co., which controls the wells and pumping plant. The water is discharged into storage tanks at Hart, and at present it is delivered in barrels to consumers. The town has about 400 people and the usual representation of business houses, among them a good hotel. A business men's league has been organized, which has done effective work in many directions. Its avowed purpose is to encourage legitimate mining. This league has also a law and order committee to assist in the maintenance of a quiet camp. The claim-holders and lessees seem to be a conservative lot of men.

Searchlight, Nevada.

The first locations in the district were made on Dec. 19, 1907, by J. H. Hart, Bert Hitt, and Clark Hitt; after these came the Foster Brothers and Andrews & Marsh.

This detached range trends north and south and is about five miles long and three miles wide. It consists of a series of peaks and spurs, some of which are connected by saddles and others are divided by deep ravines, exposing the formation. The country is rhyolite and rhyolite breccia, with three parallel zones of altered rhyolite running in the same course as the trend of the range. The gold is in the free state, disseminated through the gangue in finely divided particles. Much of it is so fine as to be invisible except with the aid of a magnifying glass. In some places there are fairly well-defined veins within these zones, but as a rule the diggings, which extend from 10 to 60 ft. deep, show the gold-bearing rock to be in masses of irregular shape. While many specimens run phenomenally high, it is believed that a general average of the ores of the district will not be far short of $20 per ton. The locations controlled by Hitt & Hart, Geo. A. Foster and associates, and Andrews & Marsh quite thoroughly cover the three parallel zones above referred to, but these parties have given a number of leases running from 1½ to 2 years, and under these the greater part of the exploring and developing of the district are being done. There are not less than twenty places in which lessees are at work, sinking and driving on outcropping lodes. The Big Chief Mining Co., controlled by the Foster Bros. and some Goldfield associates, has a lease from Hitt & Hart on the east zone. This ground covers both sides of a prominent spur. To open the lode outcropping on the crest cross-cuts are being driven from both sides, whereby a depth of 300 ft. will be gained. A shaft being sunk at the east side of this hill has struck what is reported as high-grade ore. The Pfunder and Todhunter leases, in the same locality, have encouraging showings. Andrews & Marsh, controlling the Oro Belle Mines Co., have ground which they are developing adjoining the Big Chief.

The Quartette Mining Co., which operates the Quartette mine and mill at Searchlight, has a bond and lease from Foster Bros. on the Jumbo group, situated on the west zone. This company has installed a gasoline hoist, erected a head-frame, and is sinking a shaft, which is down 60 ft. They will continue to 100 ft. and then do some driving. G. F. Sloan has a lease on a block of Jumbo ground, on which he has a 50-ft. shaft in ore that is a good average for the district. Hitt & Hart, who are themselves developing a block of their Oro Belle No. 1, report rich ore in various workings, which include a 160-ft. adit and one or two shafts.

John D. Shaffer has some promising locations at the southern end of the district, and John O'Keefe and associates of Goldfield have claims covering Twin Peaks, situated half a mile east of the Big Chief ground. This is leased to J. F. Smith, J. C. Howe, H. W. Lauck, and F. L. Earll, who have sunk a 50-ft. shaft, in which free gold is found in a saccharoidal quartz. Hart, Hitt, and Foster have installed a Little Giant quartz-mill, made in Portland, which is now operating. It is run by a gasoline engine, the ore being crushed by a rocking muller. The Hart Mining & Leasing Co. has been organized by G. A. Marsh, W. B. Andrews, and others, and has taken several properties for development.

H. M. Banfield, manager of the Garvanzo Mining & Milling Co., is making arrangements for the building of a 25-ton reduction plant, which is expected to be in readiness within 90 days. Sinking has been resumed at the Sunrise, where a 7-ft. body of medium-grade ore has been opened up the past two days while driving on the 50-ft. level. The property has been leased to Goodwin Felix & Todhunter. G. F. Sloan is in Los Angeles purchasing for his lease on the Jumbo. At a depth of 50 ft. cross-cuts have been run east and west, and the lode prospected for a width of 45 ft., which is all of milling grade. Phelps & Eagan, lessees of Block 3, Oro Belle, have started a new shaft 100 ft. north of the Big Chief adit on the west side of Big Chief Mtn., cutting an 8-ft. vein.

The opening of the Norton house, Hart's new first-class hotel, was celebrated last Friday evening with a banquet and ball. An elaborate menu was served, and with Harry S. McCallum as toastmaster the affair proved a huge success. The furnishings in the Norton house are first class. Another two-story business block was started this week by Martin & Nance.

The McCracken Hill mines, situated in Signal district, Arizona, 40 miles from Yucca station, are owned by an eastern company, of which John L. Witney is manager and Albert Burch consulting engineer. Extensive development is in progress on a great silver-lead vein whose outcrop is traceable for a distance of 10,000 ft. through a gneiss and grano-diorite country. The vein is of great width. The ore consists of lead carbonate and silver chloride near the surface, and of galena and silver at greater depth. A 400-ft. incline three-compartment shaft has been sunk on the vein and further sinking is in progress, with horizontal workings on the vein. Gasoline engines, using distillate as fuel, furnish the power. The company is putting in a 20-mile pipe-line, through which a water supply will be brought by gravity. A force of about 75 men is employed. This locality is 14 miles north of the Bill Williams fork and 70 miles by road from Parker.

DENVER, COLORADO.

New Railroad Begun.—Gilpin and Adjoining Counties.—Clark Buys Coal Lands.—Activity at Steamboat Springs.—Franklin Mining Co.—Fremont Coalfield.—Cripple Creek Output.

The construction of the Denver, Laramie & Northwestern railroad was begun on May 2 at Denver, with appropriate ceremony. When complete the line will be of great importance to Denver, as it will afford direct connection with Seattle, and open up rich agricultural lands and previously inaccessible mining districts in Wyoming and Idaho.

Mining in Gilpin and adjoining counties is being actively carried on as the season advances. At Central City a new gasoline hoist has been installed at the War Dance mine. A large electric pump is being set at the 1300-ft. level of the Cook shaft, which is on the property of the King Bee Mining & Milling Co. Several of the producing mines are shipping steadily and others are undergoing vigorous development. An order for 40 new cars has been placed by the manager of the Newhouse tunnel. The cars are much larger than the present ones, and are rigidly constructed to withstand dumping by derrick, which is to be tried. The Wano mill at Jamestown has begun to treat ore again. Sufficient water is now assured for steady operation.

Senator W. A. Clark has taken up the option which he held on 12,000 acres of coal-land near Stonewall. Development work on an extensive scale will start at once on the property, and a spur line will be laid from Trinidad. The object is to furnish coke to the United Verde smelter at Jerome, Arizona. A great deal of development work is being done on properties near Steamboat Springs. The owners of mines in this district are making every endeavor to have their properties ready to ship ore as soon as the Moffat road reaches there. Prospectors are very active all along this new line. At the recent annual meeting of the Franklin Mining Co. in Boston three new directors were elected, and Steven R. Dow made president to succeed F. H. Raymond. This company operates largely in Colorado by leasing.

Recent explorations in the extreme southwestern portion of the Fremont county coalfield show the coal area much thicker and of wider extent than formerly supposed. The first seam was encountered at 300 ft. In the next 536 ft. 33 distinct seams were passed through. Further prospecting outside the known area and at greater depths is going on. Cripple Creek finished the month of April with a gross tonnage of 64,023 tons, which exceeds that of March by 3000 tons. The gross value was $1,346,380, being $38,700 less than for the previous month. The local cyanide mills treated nearly 12,000 tons of the low-grade material. The new Stratton's Independence mill should add materially to this amount for May. The excessive low-grade tonnage from nearly 100 dumps that are being worked by lessees cut down the total value of the product. Square-set timbering has been resorted to in the Portland mine, to support the walls of the abandoned stopes between the fourth and fifth levels. When the miners had completed the difficult and dangerous work on April 22 each man received a present of $50 in gold from the company.

As spring advances there is increasing activity among the smaller properties at Leadville, and especially in regard to schemes for development of the adit. For many years this plan was frowned upon in Leadville. The principal mining areas are of gentle slope, in which adits gain depth but slowly, and the life of the mines was expected to be short until the deposits at lower levels were discovered. J. F. Horner has completed arrangements to drive an adit from the Shields mill-site northwest through the Red Bird, Tiger, Venture, Welsh, and other properties—a total distance of about one mile. The Home Co. proposes to drive an adit 3000 ft. long at Granite to cut the veins on the Yankee Blade, Robert George, Magenta, Bunker Hill, Washington, and other properties. Mining in a desultory way has been carried on in the Granite district since 1868. During the three years following the first discovery an important production was reported from the various shallow workings, among which the Yankee Blade was most prominent. After a period of inactivity Granite experienced an awakening in 1894, and active mining continued until the sulphide zone was reached, and the abundance of water made operations unprofitable. It is believed that the new adit will bring the Granite district once more into the producing rank. Since the lessees on the Hibschle at the head of Eighth Street completed the improvements on the shaft, shipments have gradually increased until they amount to 100 tons daily. This ore is principally manganiferous, although the strike made recently in the Wolcott workings adjoining the Hibschle was principally lead. The present workings of the Hibschle are several hundred feet from the main shaft and at a depth of about 500 ft. While Robinson is not in the Leadville district proper, the International Mining Co. has attracted much attention, local capital being interested in the enterprise. At present 60 tons daily is being shipped to the smelters. Developments on the orebody show a strong shoot of iron-sulphide, which is accompanied by the usual lead and zinc ores characteristic of the district. About 400 tons per month is being shipped from the Hilltop property in the Horseshoe district to Kansas smelters. Repair work on the Ohio & Colorado smelter at Salida has been completed and the capacity of the plant increased one-third.

BUTTE, MONTANA.

Barnes-King.—Boston & Montana Directors Elected.—Montana Mining Association.—Large New Chimney at Great Falls.—Reduced Cost of Production.

For the first time since the organization of the Barnes-King Development Co., the mine more than paid expenses during March and April. The detailed report for March shows that 5655 tons of ore were milled during the month, the bullion output plus the tailing at 49c. per ton, giving an original ore-value of $4.97 per ton. The bullion was 1791.25 oz., for which the United States assay office paid $25,320.13, less assaying charges of $119.80. Twenty-five per cent of the men employed underground are engaged in development work. General Manager McGee continues hopeful, and some of the stockholders in Butte, who paid $5 per share for stock now selling at 60c., even see the remote possibility of small dividends.

The annual meeting of stockholders of the Boston & Montana Consolidated Copper & Silver Mining Co. was held in Butte recently and the old directors re-elected: Sidney Chase and James Phillips, Jr., of Boston; David B. Hennessy and Andrew B. Grafius, of New York; and John D. Ryan, of Butte. Out of the 150,000 shares of stock, 149,541 were represented at the meeting. No other business was transacted.

A. H. Wethey, general mine manager for W. A. Clark, says the report that Clark has sold his Montana interests to the Amalgamated Co. is not correct. Mr. Clark is making a trip through Arizona and California, and is expected back in Butte about May 15. Clark's interests in Butte include the Stewart, Original, and Elm Orlu mines; the Butte Reduction works, the street railway system, a bank, and other properties.

It is announced by officers of the Montana Mining Association that the Association's smelter at Ponderay, Idaho, will be ready to receive ore about May 18, with a capacity of 250 tons of ore per day to start with. The Association is now negotiating with the Great Northern and Northern Pacific railroads for rates, which, when made, will have to be approved by the Inter-State Commerce Commission. The Association does not expect any difficulty in getting favorable rates. It is expected that the smelter will do much for the mining industry of Montana, as it will stand in the way of future prohibitive rates by the 'trust' smelters.

Work on the big stack at the Great Falls smelter of the Boston & Montana Co. is well under way, and it is expected that it will be completed by October 1. The stack will be 742 ft. above the blast-furnace charging-floor, being situated on a high point above the smelter. The actual height of the chimney above its foundation will be 506 ft. It will have a diameter of 74 ft. The flue which is being built to

connect the furnace with the stack will be 1800 ft. long, and 1450 ft. of it will be 48 ft. wide and 20 ft. high, while the remaining 350 ft. will be 175 ft. wide and 20 ft. high. The big chimney, when completed, is expected to carry off every minute 4,000,000 cu. ft. of gases. About 100 men are employed on the work, including 50 expert high-chimney men. It is stated that the chimney was planned to meet any contingency regarding the Washoe smelter, as the Great Falls plant could then easily be enlarged to handle all the ore of the Amalgamated mines.

The present copper production of the Amalgamated, North Butte, and Butte Coalition companies is at the rate of about 26,000,000 lb. per month, and it is asserted by the officers of the companies that the average cost is less than 10c. per lb. That the companies are making cheaper copper than formerly is evidenced by the fact that during the past week orders were issued to all bosses to send lower grades of ore to the smelters.

On account of the long shut-down of the mines prior to March 1, the net proceeds of mines for the year ending June 1 will show a decrease from that of the preceding year of about $14,000,000. The net proceeds for the year ending June 1, 1907, were about $23,000,000.

TORONTO, CANADA.

Cobalt Company's Title Confirmed.—Ontario Legislature Disregards Vested Rights.—Government Interrogated on Lawson's Yukon Gold.

The Canadian Government, which was urged to disallow the act passed last year by the Ontario Legislature confirming the title given by the Provincial Government to the Cobalt Lake Mining Co. in view of a claim put forth by the Florence Mining Co. on the ground of prior discovery, has refused to interfere. The matter has for some time been receiving consideration by A. B. Aylesworth, Dominion Minister of Justice, who reported to the Government in favor of non-interference on the ground that the Provincial act is clearly within the jurisdiction of the Legislature as defined by the constitution, as it concerns property and civil rights which fall within the scope of Provincial legislation. Theoretically the Dominion Government has the power to review and if it so pleases to annul any Provincial legislation within one year from the time of its enactment, but the Minister of Justice held that it was not advisable that the Federal authority should consider the justice or propriety of Provincial laws, so long as they were clearly within the jurisdiction of the Legislature. At one time the opposite view prevailed and Canadian Governments undertook to pass upon the Provincial measures, but lately the tendency has been to restrict the exercise of the power of disallowance to cases where the Legislatures exceeded their constitutional limitations, and not to veto legislation simply because it is bad in principle. With this decision the action of the Florence Mining Co. to recover the property, which was suspended until the disallowance question was settled, falls to the ground, and the title of the Cobalt Lake Co. is apparently secure against further attack from any source. But the result will hardly tend to create a feeling of security on the part of American investors in Ontario mining properties, as it renders the Legislature, that is to say, the Government of the day, practically free to deal with their holdings as they please, or as suits their interest, without any sort of check on the action of a Legislature of a single chamber entirely subservient to the administration. 'Vested rights' is a term quite without significance in the dealings of the Ontario Government with mine-owners.

The attention of the Canadian Government is being called to Lawson's Yukon Gold Co. flotation, Claude Macdonell, one of the parliamentary representatives of Toronto, having given notice of a series of questions which he will put in Parliament with the object of ascertaining the true status of the company. He will ask whether the statements made as to the holdings of the company in the Yukon are correct, and if any were incorrect or misleading what steps were taken by the Government to warn or protect the public that was asked to invest.

MEXICO.

Carrizo Smelter.—Casados Consolidated.—El Tajo.—Lawson's Expenditures at Mascota.—Parnaso District.

After a little over two years of hard work and patient endeavor the Carrizo Copper Co., in Ayutla, Jalisco, has about completed its little 50-ton smelting plant and is now in the market for custom ores. In addition to the products of its own mines, this company has the mines and mill of the Ayutla Copper Co. under lease, and will smelt the concentrate from that mill, which has now been in operation for six months or more. The Carrizo plant should prove a boon to the many small copper-producers around Ayutla, Autlan, Purificacion, and throughout that region, for it is a long and expensive haul to the railroad station at Ameca or to the Pacific coast, and the smelter, by reason of concentration into matte and a material reduction in the volume of freight, can offer considerably better terms than it has been possible to obtain at this distant point. Kent E. Keller, of St. Louis, has been unceasing in his efforts to bring this property to a successful stage, and he now expects that before the end of May the blast may be turned on and smoke be pouring forth from his stacks. Because of the great expense of getting coke into Ayutla, as much charcoal as possible will be used with the coke in smelting, and the greatest economy will be practised at every point. The plant is built so that the capacity may be increased as the business demands.

Another Jalisco property which is fast approaching the successful line in the procession is the Casados of the Consolidated Mining Co., in the Hostotipaquillo district. This property was bought and the company organized by W. R. Ramsdell of Etzatlan, and is one of the few that has borne out the old traditions of encountering rich ore just as the water came in and drove the old workmen out. The shaft and old workings were unwatered without a great deal of difficulty, and the rich ore found as had been claimed. A great deal of repair work throughout was necessary, however, so that something like ₱50,000 has been expended to date, but the company is now shipping a high-grade product to the Torreón smelter and the second grade is being sent to the near-by Amajac reduction plant (patio and cyanide) of Carlos Romero, pending the development of the property sufficiently to warrant the erection of its own concentrating and cyanide plant. West of Hostotipaquillo, near San Sebastian, also in Jalisco, the development work in both the old workings and the new tunnel on El Tajo, operated by the MacKeever Bros., is said to have opened up sufficient ore to run a fair-sized plant for several years, and orders have been placed for a 30-ton stamp, table, and cyanide experimental plant to thoroughly determine the needs of the ore.

A day's ride to the south from San Sebastian is Mascota, the headquarters for Thomas W. Lawson's Mexican company, and east of which, about two or three hours' ride, are the principal holdings, some 138 scattered pertinencias (340 acres), for which it is said $165,000 was paid and $500,000 spent on development work and plant. In the little narrow arroyo of Tethuana is situated his pretty San Gregorio 30-ton cyanide mill, on which $250,000 is supposed to have been expended; though probably the greater part went into the magnificent wagon-road over the mountain and through the woods to the saw-mill which was put in to furnish timbers and lumber for the erection of the cyanide-mill. These form the basis for the $5,000,000 company organized in Boston, and after a hurried trip over the country one could not help being reminded of Lawson's 'Frenzied Finance' and the 'Lambs.' West from Mascota about a day's ride, at a place called El Moral, the company is supposed to have a cinnabar mine and furnaces.

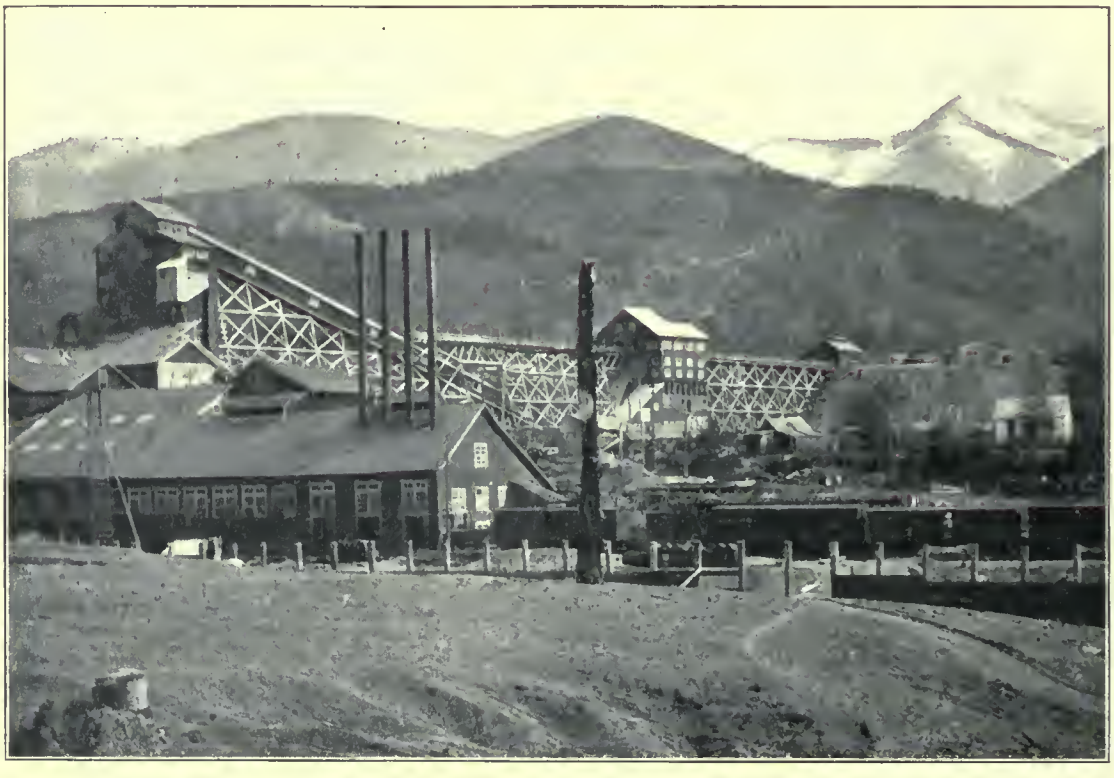
The owners of the Boca Ancha, in the Parnaso district, have completed their 50-ton concentrating and cyanide plant for the treatment of the old dumps, and while steam is at present being used, an electric plant is being designed for erection on the Parnaso river, on the completion of which more active development work will be inaugurated at the mines.

FROM MINE TO BATTLESHIP.

The Story of the Manufacture of White Lead Paint.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The original source of the white paint that protects the steel of the battleships now gathered in the Bay of San Francisco is the lead ore of a mine. The smart appearance of the serried squadrons is due to the pure pigment manufactured by a series of intricate processes from the mineral broken many hundred feet underground by the labor of the miner. From the dark and cavernous openings of the underworld has come the substance that now gleams in the sunlight of California. Many mines produce lead ore and many smelters extract the metal from its earthy matrix. The Selby smelter, at the northeastern end of the Bay of San Francisco, is the most important establishment of its kind on the Pacific Coast and it supplies the white lead used at the Mare Island navy yard. Of the mines from which ore is sent to the Selby works, the most important is the Bunker Hill & Sullivan in Idaho. It is my purpose to trace the lead ore from the mine to the smelter, and then to follow the lead from the furnace to the plant in which the white lead pigment is prepared, thence to the navy yard, where it is laid upon the sides of a battleship. It is the story of a complex industrial process.



Main Mill Building. Ore-breaker. Kellogg Adit.

The Bunker Hill & Sullivan Mine and Mill, at Wardner, Idaho.

Extraction in the Mine.

The Bunker Hill & Sullivan mine is the most important single lead-producing mine in America. It produces 40,000 tons of lead and 1,650,000 oz. of silver annually. Since its discovery this mine has paid $10,146,000 in dividends. The property is situated at Wardner, in the Coeur d'Alene, Idaho; it is a picturesque region, mountainous and forest-clad. To the picturesque in nature has been added the romantic in human history, and to these have been superadded the horrors and brutalities of industrial warfare, for in 1899 and for many years thereafter this locality was the scene of a bitter struggle against the worst forms of labor unionism. On April 29, 1899, the large concentrating mill of the Bunker Hill & Sullivan Mining & Concentrating Co. was destroyed by an explosion of dynamite, placed by rioters. The accompanying picture shows how the ruins appeared, and it will be seen that the only cheerful feature of the scene is the flag that floats undaunted at the top of the mill. It was hoisted after the explosion, when the troops came to restore order, for Frank Steunenberg, the Governor of Idaho, subsequently assassinated for doing his duty, had said that his purpose was "to bring Idaho back into the United States." Order was finally restored and Wardner became a peaceful settlement once more, but not before representative government had been severely tried.

This mining property, which became so famous by reason of the labor troubles and which later proved to be so magnificently productive, is a consolidation of many claims, the first of which was located in September 1885. From time to time, the territory controlled by the company has been increased by purchase, until now the group of claims covers about 3000 acres. From the very beginning the production of silver and lead has been almost uninterrupted; what stops there have been were due not to any exhaustion of ore reserves but to unsatisfactory metal markets or to disturbed labor conditions. The

productive zone of this property is known to be over two miles long and the deepest opening is 2200 ft. below the surface of the mountain into which the mine workings extend. The accompanying photograph shows the mill and the entrance to the main adit, which is named the Kellogg tunnel. It can be seen just above the small building on the right, and penetrates the mountain in the background.

The mine is said to have been discovered by a donkey, who strayed from his owners and was found standing on the ore; he had pawed the ground so as to remove the turf covering the outcrop of the lode. The incident is related in the judicial records of Idaho. Early in the history of the mine there was some litigation and Judge Norman Buck of the District Court said in his decision that: "From the evidence of the witnesses, the Court is of the opinion that the Bunker Hill mine was discovered by a jackass, Phil O'Rourke, and N. S. Kellogg; and as the said jackass is the property of the plaintiffs, Cooper and Peck, they are entitled to a half interest in the Bunker Hill, and a quarter interest in the Sullivan claims." In other words, it was decided that Cooper and Peck, merchants in the neighboring town of Murray, had grubstaked or outfitted Kellogg and O'Rourke.

The rock in which the ore is found is a very old quartzite, formed by the metamorphism of sandstone, which has been twisted, crushed, and distorted by geological movements. In the cracks and fissures formed by such movements, the lead ore has been deposited as galena, which when pure carries 86.6% lead, and 13.4% sulphur. With it is associated a nearly fixed proportion of silver, in the ratio of one ounce of silver to 44 pounds of lead. The parts of the mine from which the ore is extracted are irregular in shape, although the continuity of the lode and a certain rough alignment of the orebodies within it have become emphasized by the operations of many years. When I visited the mine in 1904 the Kellogg adit was 12,000 ft. long and a new orebody had just been discovered at the face or eastern end. The quartzite appeared to be full of slips and fractures, which serve as local boundaries for the richer bodies of galena. A main foot-wall marked the southern limit of the ore-bearing zone, which had a dip of 50° southward. The galena replaces and impregnates the brecciated quartzite along channels created by the fractures extending along this foot-wall and away from it into the overlying rock. Fig. 1 is a sketch of one of the headings.

The Bunker Hill Mill After the Explosion on April 29, 1899.

The photographs, taken by flash-light, will illustrate the appearance of the stopes where the lead ore is being extracted. These openings are from 100 to 140 ft. wide, and they have been made as long as 1500 ft., leaving cavernous spaces that would entail dangerous falls of rock if they were not filled subsequently with waste material, as the ore is removed in the course of mining. No less than 4,500,000 ft. of timber is used annually to sustain the ground and protect the workmen until the cavity or stope is filled with waste broken in cross-cuts and other exploratory openings of small size. Despite these precautions accidents do occur, although they are rarely

fatal. Occasionally the mishaps to the miners lead to deeds of heroism and to the display of technical ingenuity in making a rescue. Thus only a month ago there was a collapse of rock separating a new stope from an older excavation overhead. On March 26, the rock between the two openings of the Kemp stope on No. 10 West, as it was known to the foreman of the mine, showed signs of caving. (See Fig. 2.) Two timbermen were sent to 'catch up' the caving ground and make it secure. The miners were withdrawn from the stopes. At 3 o'clock in the afternoon the ground began to cave badly, filling the manway and chute from the western portion of the stope and falling to the level below. An immediate examination indicated that there was no apparent possibility of extricating the timbermen. Just as fast as the broken rock was drawn out of the chute and manway (C), to the No. 10 level, in endeavoring to clear a way to the place where the men were supposed to be, the caved material would settle in the upper stope and induce a fresh collapse from overhead. To overcome this condition, long timbers were formed into a mat (A) and on this other timbers were piled in the upper stope, beneath the point (B) where the caving was worst. Then the material was drawn as quickly as possible at the level below through the chute at C. Many hundred tons were removed and this caused the mat of timbers to descend. The ground continued to cave until the mat reached the top of the chute and manway, where it stayed, sealing these openings so that finally they could be emptied from below, and at the same time this mat of timbers afforded protection from the caving still in progress above. This was accomplished by 10 o'clock at night and the rescuers, climbing up the manway, found one of the timbermen a short distance from the head of the passage and pinned in a narrow space (X) between masses of rock and timbers, yet enough to one side to have escaped being crushed by the descent of the rocks that had swept down the manway and chute. He had been in the greatest danger and would inevitably have been killed had any other method been adopted. This man stated that his comrade was in a small drift (Y) leading from the stope, now completely sealed by the fallen rock. It was decided that to drive through the cave and the mat of timbers was impracticable, the entrance to the drift being above the timbers. Therefore the manager, who led the rescue-party, decided to make a passage through solid rock from the top of the manway. Communication with the imprisoned man was established by an air-hose, which happened to be connected to a machine-drill standing in the drift close to the timberman, and by actual conversation through this tube it was ascertained that he was unhurt and had plenty of air. Blasting had to be avoided, although the ground was "quite stiff," on account of ventilation for the rescuers and for the imprisoned man. The shock of a blast was pretty sure to start more caving. So the entire distance of 15 ft. was cut out by Waugh stoping-drills, fitted with a chisel-bit. In 17½ hours the rock was cut out in blocks and the interior drift was reached, the man being taken out at 7:30 in the evening, after facing death for 28½ hours. Thus even the lead that yields the white paint on the battleship in San Francisco bay is not without incidents as thrilling as those of naval warfare, and not without the exhibition of a resourceful courage such as an admiral might envy. For the manager of the mine, Stanly A. Easton, worked without cessation for 29 hours, directing the rescuers and leading the way to the rescue. And when it was all over and the two timbermen were safe in their homes, he wrote to the president of the company thus:

"This gives a new application for the useful Waugh drill. One machine did practically the whole work, running constantly for fifteen hours, there being relays of four men, who practically held the drill up to the face for its work with main strength, in the same manner as coal punchers are handled. The ground was too hard for any progress to be made through it by picking and mailing, and what would ordinarily be called stiff blasting ground. I am writing you complete details of this incident as you will no doubt see Associated Press despatches concerning it and also as there were certain methods used which, so far as I know, are entirely novel and which proved in this case to be exactly the right thing to do. The situation was a nasty one and we are mightily well pleased that both the men are safe and sound, which is due principally to the hard work of the miners in carrying out the plans agreed on by Mr. McDougall, Jones, and myself. It took just 28 hours of solid work to carry the thing through. The damage to the stope is insignificant, as the broken material is practically all waste from the hanging wall and no ore is either buried up or lost. The organization of the crew is disturbed for two days, but the output of ore seems to have fallen off but very slightly."

If the American fleet has many men like this, it ought to ensure America from invasion!

In the course of my examination of the mine in 1904 I walked through 4½ miles of workings. The additional work since that date has increased the length of the main workings to 6 miles, including the Kellogg tunnel, which is nearly 2½ miles long. Through this adit, which took 8 years in construction and cost over $200,000, the ore is hauled, by electric locomotives, to the mill. Every year, through the portal of this mine, there is brought enough ore to provide every man, woman, and child in the United States with one pound of lead, and even then there is some left over. Besides serving as the main entrance or adit of the mine, the Kellogg tunnel serves to ventilate the workings by connection with other and higher drifts and shafts penetrating the ground overhead. The mine is well ventilated and this is particularly necessary where lead ore is being handled, for lead is poisonous to the human system. However, the men rarely suffer from contact with it, immunity being due principally to the fact that the metal, when occurring as galena, the sulphide, is in an insoluble form and is not readily assimilated by the body. Furthermore, the dust is mitigated by sprinkling dry drifts, so that cases of lead poisoning are only at the rate of one or two in 10 or 15 years.

among 500 employees. Sanitary precautions are strictly enforced. About 80% of the men working in this mine are native born Americans, although many are of Cornish descent, their forefathers having been miners for many generations. Of the entire force nearly 60% are married and many own their own homes at Wardner and Kellogg, the adjacent towns. The Bunker Hill & Sullivan has been in operation so long that many of the miners and foremen have worked in no other mine.

At the time of my visit I watched the methods employed in breaking the ore. A sollar or platform, made of 3 by 10 in. boards, is laid on the floor of the stope and the ore is broken down upon this, some fine waste being spread on the boards to protect them from the blast. Machine-drills are used to

The Coeur d'Alene, Idaho.

drill the holes, which are 7 to 10 ft. deep, 2 in. diam., and loaded with gelatine dynamite, exploded by a cap to which a fuse is attached. After blasting, the larger pieces of quartzite are removed by hand (to be used as filling) and the remainder is shoveled into chutes or mill-holes, 25 ft. apart and lined with round poles, 6 in. diam. at the small end. These chutes lead from the stope-floor down to the level, through the stope that has been already excavated and filled. At the level the ore is drawn into cars, each of 3 tons capacity, formed into trains, and hauled by electric locomotives. The ore is stoped for its full width, so as to explore as well as extract. Ordinary drifts might go through almost barren ground within the core of an orebody. Fortunately the barren quartzite breaks in blocks while the lode shatters into small pieces, so that the larger fragments of waste are easily picked out for filling, while the ore is collected into chutes. If the output of a stope is hurried so that the rock broken is not turned over carefully and the lead gleaned before the next blasting, there is a loss due to burying the lead under quartzite. There is also an inevitable small loss through the galena left on the faces of rock that is retained as waste, and there is a loss from the pulverization of the mineral by blasting and breaking, but usually less than one eighth of 1% goes into the filling. Rarely a piece containing 2% may be lost and also some galena dust. The waste is occasionally

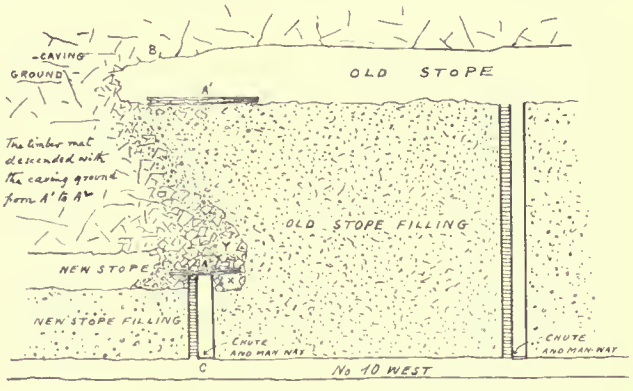


Fig. 2.

drawn from one stope to another and is then examined. The presence of a trace of moisture lessens the dust arising from the broken ore. In fresh rock the ground appears dry, but after a while the moisture exudes. This water is not acid; it contains iron in solution, derived from siderite, the carbonate of

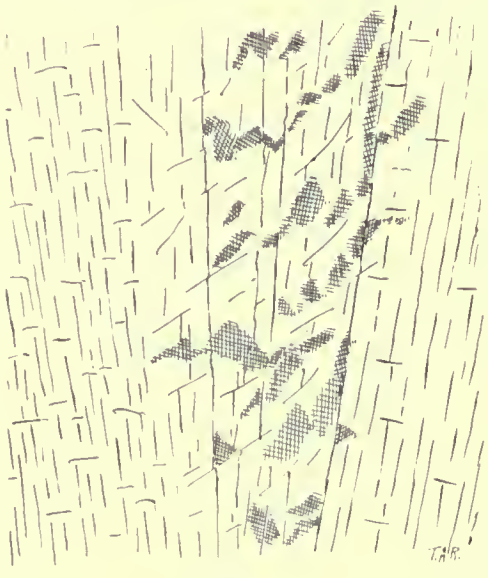

Fig. 3.

iron, which occurs in adjacent veins. At the surface the water from the mine precipitates iron hydrate, which dehydrates to ferric oxide.

The accompanying sketch shows the face of a small stope, the quartzite being more thinly laminated on one side than on the other, and with a different dip. The dark lead ore crosses the laminations of the zone of fracture in an irregular way. (See Fig. 3.)

After a visit underground, I climbed through old workings to the surface and saw the place where the lode was first discovered. The site is marked by a big open-cut situated close to the line of the Stemwinder claim. An outcrop of galena was found here and as the ridges of quartzite were prominent they

were assumed to be veins, although, as was proved later, the lode crosses them at a strong angle. In consequence of the first mistake, the claims were located across the strike of the lode, so as to cause numerous lawsuits arising from the interpretation of extra-lateral rights. As seen in the open-cut, the lode is a strong cross-fissure cutting the bedding of the quartzite along a sheer-zone marked by brecciation. The most prominent structural feature is the foot-wall, which limits the mineralization northward. The lead ore occurs within this sheer-zone, along the foot-wall, along the fractures that are roughly parallel to the foot-wall, and in irregular masses having a course that appears to be determined by the bedding planes of the quartzite, which, being shattered and disordered near the main line of fissuring (that is, the foot-wall) produces a confused mineralization, tending to more evident shape and direction westward as the orebodies extend away from the foot-wall. While standing at the point of discovery I found a piece of quartzite showing beautiful ripple marks, indicating that the metamorphism to which the rock had been subjected has not been able to obliterate the traces of sedimentation. The sight of those ripples, fixed in the hard quartzite that encloses the valuable ore, took my imagination back to that remote geological period, many million years ago, when the shallows of the Algonkian sea were ruffled by a gentle breeze, leaving its imprint indelibly recorded on the soft sand from which the alchemy of nature had fashioned an adamantine rock, now laboriously penetrated by man in his search for metallic wealth.

Treatment in the Mill.

From the mine the ore goes to the mill, where it is crushed, classified, and concentrated, so as to get rid of the worthless matrix of quartzite (and some siderite) and collect the valuable minerals in a clean and marketable material. Argentiferous lead, in the form of galena, constitutes the chief product, but there is also the iron pyrite, with which silver is associated in the final concentrate. The problem is to save the lead and silver without the zinc.

The electric locomotive pulls the cars (holding 7000 lb. apiece) to large storage bins; there the ore falls over grizzlies (parallel inclined steel bars 1¼ in. apart), the oversize going to a Comet crusher, size D, of the gyratory type, of which there are two, one being held in reserve for such times as repairs are needed. By this machine the ore is crushed to a maximum diameter of 2½ in. and then spills onto a horizontal picking-belt, where a couple of men are stationed to pick out the clean ore (galena) and the inevitable mine rubbish) by hand. This belt delivers to roughing rolls, and from them, after being reduced to a size of about 40 millimetres, the ore is discharged onto an incline belt-conveyor. Here it is joined by the undersize, which passed between the bars of the grizzly and is brought thither by another belt-conveyor.

The joint product is now carried to the top of the mill proper, a height of 100 ft. in a horizontal distance of 300 ft. There it is fed into a Vezin sampler, the sample extracted passing to another sampling machine of the same kind placed immediately underneath. Each sampler takes one tenth, so that one per cent of the whole is finally obtained. This sample is reduced and prepared for assay daily.

After sampling, the ore drops into the mill bins, which have a capacity of 600 tons, equivalent to a 12-hours supply. From the bins the ore passes through a pair of trommels, or revolving cylindrical screens, one for each of the two units into which the plant is divided. The upper section of each trommel has round holes of 18 mm. diam., while the lower section has holes of 36 mm. The oversize from the upper section goes to rolls (placed at the bottom of the mill) and is re-ground by other rolls, before being returned (by a bucket-elevator) to the same trommel. The size larger than 18 mm. but smaller than 36 mm. goes to the bull-jigs, which produce the three usual products, namely, concentrate, middling, and tailing. The first is shipped to the smelter. The middling is re-ground by rolls to the next size, the trommel sizes being 36 and 18 mm., as stated, followed later by 10, 7, and 3 mm. openings. At each stage of the re-grinding by rolls, the product is screened through these trommels, to be treated by jigs, until finally it gets below the 3 mm. diameter. After this reduction the middling from the remaining concentration processes is re-ground by Huntington mills, instead of rolls. The classification of the re-ground product (now less than 30 mesh) from the Huntingtons is effected in two ways, namely, by spitzkasten or pyramidal boxes, and by Callow settling-tanks. The overflow from the last goes to Frue vanners, while the underflow passes to Wilfley tables.

The finest revolving screen (or trommel) has apertures of 3 mm. diameter and after the crushed ore has passed through this, it is hydraulically classified, the sand being concentrated on jigs while the slime is conducted to a settling-tank, from which it is drawn for treatment (together with the re-ground product coming from the Huntington mills) on Wilfley tables and vanners.

Middlings from the 10, 7, and 3 mm. jigs, together with all the tailings from the sand-jigs, Wilfleys, and vanners, are carried by launders to the annex, where they are classified and dewatered by Callow screens, the oversize (above 26 mesh) being re-ground in Huntington mills, while the undersize is re-treated on Wilfley tables and vanners.

Among the principal features of the mill may be mentioned the re-crushing by rolls, the passage of the coarse middlings through the rolls, and the grinding of the fine middlings in Huntington mills. Water is used to wash the vanner concentrate into an orifice (at the bottom of the front boxes) leading to the bins. The end treatment, after classification, consisted, at the time of my visit, of four sets of jigs, the overflow from which went to settling-tanks, the middling from these finishing jigs being ground in Huntingtons while the fine overflow passed to Frues and the coarse overflow to buddles, followed by Wilfleys. The buddles are now no longer used and Callow screens form an important feature in the equipment. Card concentrators are now being tested, with promising results. It has been suggested that a

filter-press be employed to catch the fine galena carried in suspension in the mill-water; the result of such an experiment will be awaited with interest.

In March of this year the mill treated 30,600 tons in 28 working days. The ore assayed 12.56% lead and 5.07 oz. silver, so that the material treated contained an aggregate of 7,686,720 lb. lead and 155,142 oz. silver. The ratio of concentration was 4.6 into 1.

The yield, as determined by sampling and fire-assay, was:

Class.	Weight. Tons.	Lead. %	Silver. Oz.
First	1,169	76.8	28.6
Second	2,866	50.3	18.2
Slime	1,097	44.9	18.0
Middling	1,448	10.3	4.2
Total	6,580	45.3	17.0

Thus there was extracted 5,965,096 lb. lead and 111,598 oz. silver, the total recovery being 79.4% of the

Getting Ready to Blast Big Pieces of Ore.

lead and 71.9% of the silver, or 77.6% of the total lead and silver in the ore. Of the above mill-products, only the middling is re-treated, the others are

In a Stope of the Bunker Hill & Sullivan Mine.

shipped to the smelters at Tacoma (Washington), Selby (California), Pueblo and Denver (Colorado), Perth Amboy (New Jersey), and occasionally elsewhere. In the mill, 52 men are employed; the total cost of milling in March per ton of crude ore was 35.9 cents; this cost for many years did not exceed 21 cents per ton, and it has been increased by reason of the more complicated treatment adopted in order to obtain a higher extraction.

Besides the different concentrates saved in the mill, the mine yields a varying amount of selected ore, picked in the stopes and at the top of the mill, as previously described; this is shipped directly to the smelters. The proportion of this product sold from month to month depends upon the condition of the market. In March 250 tons only was shipped; this contained 58.8% lead and 19.2 oz. silver per ton. There have been months when as much as 3000 tons of such ore was sent to the smelters. The cost of producing lead, laid down at New York, in March, was 2.3 cents per pound. In the year ending March 31, 1907, the Bunker Hill & Sullivan Mining & Concentrating Co. mined and milled 336,630 tons of crude ore, the cost for stoping being $1.47; for exploration, 9.4 cents; for improvements, 30 cents; tramming from mine to mill, 7 cents; concentration, 25.5

Map Showing Position of Selby Smelter Relative to San Francisco.

cents; shipping expense, 5.1 cents; general expenses, 19.5 cents, the grand total for all operating costs being $2.438 per ton. The railroad freight, together with smelter charges (direct and indirect), amounted to $5.16 per ton of crude ore. The freight ranges from $4 per ton to Tacoma to $8, which is charged to Selby and Denver. On ore and concentrate, as shipped, the total cost of freight and smelting is $19.61 per ton the mill product being, as we have seen, a concentration in the ratio of a little over 4½ into 1.

Such ore and concentrate as is sent to Selby, is transported by rail to Portland, by way of Tekoa, and thence over the Shasta route to Vallejo Junction, where the Selby smelter is situated. The distance from the mill to the smelter is 1150 miles.

Smelting the Ore.

The works of the Selby Smelting & Lead Co. are a mile from Vallejo Junction and 29 miles from San

Francisco; they were founded in 1868 by Thomas Selby, a pioneer hardware merchant of San Francisco. In 1864 Selby built a shot-tower on the corner of First and Howard streets, where it stood until the earthquake-fire. He imported his lead from Spain and England; and finding this both awkward and costly, he conceived the idea of treating the lead ores yielded by the mines of the Pacific Coast, and started to make his own lead in 1868. After his death, in 1875, the business was incorporated, A. J. Ralston becoming president and H. B. Underhill, Jr., secretary, of the Selby Smelting & Lead Co. In 1905 the control was sold to the American Smelters Securities Corporation, and Mr. Underhill became president. The operations of the plant are varied, and the importance of the works may be gauged by the fact that they refine $25,000,000 worth of gold and 12 to 15 million ounces of silver per annum. The smelter gets a variety of products from different localities, but its chief supply consists of the argentiferous lead ore from Idaho and the silicious gold-silver ores of Nevada. The Bunker Hill & Sullivan mine sends crude ore, 'bull-jig' concentrate, fine concentrate, and slime. The last of these has to be briquetted before being smelted, so it is first mixed with fine roasted ore and silicious material (from Tonopah or Goldfield); slaked lime is used as a binder, the briquetting being done in a Boyd press. The bricks from this machine, after drying, are ready for the blast-furnace.

Since the ore supply at Selby is usually irregular and the material smelted rather high-grade, it is not expedient to carry large stocks or to form bedding-floors. From the bins the ore and concentrates are taken to the feed-floor, where they are shoveled by hand into the blast-furnace. This is 36 by 144 in. at the tuyeres. The blast is under a pressure of 33 to 34 oz. per square inch. From 130 to 140 tons of charge is treated per day, exclusive of fuel and slag. Of the charge 60 to 70% is ore. It is aimed to have 15% of lead on the charge. The Bunker Hill product usually constitutes about one-sixth to one-seventh of the whole, the other lead in the charge coming from roasted matte and refinery by-products. The charge consists of:

Lb.	Description and Source.
2,500	Briquetted slime (Bunker Hill), fine iron and silicious ore.
1,100	Roasted matte.
1,000	Limestone (Santa Cruz).
800	Silicious ore (Tonopah or Goldfield).
800	Lead ore, as 'bull' jig concentrate or crude ore (Bunker Hill).
300	Refinery by-products, mainly litharge.
200	Metallic iron (San Francisco).
1,000	Coke (Australia).

This makes 7700 lb. altogether, to which 20% of old slag is added, making 9250 to 9500 pounds.

The roasted matte contains 12% lead, 12% copper, 45% iron, 3% zinc, and 7% sulphur. The slag is returned mainly in order to regulate the physical condition of the furnace and to correct irregularities in its operation. It is the aim to make a slag of the following composition:

%		%	
31	SiO_2	18.5	CaO
35	FeO	7	Al_2O_3

The alumina comes in the silicious ores from Nevada. The slag also contains 1.5% MgO from the limestone, 1% Pb, 1 to 1.5% S, and 2.5% Zn, besides traces of copper, antimony, phosphorus, etc., in fact, minute traces of most of the elements.

The limestone is the reject from the portland cement works at Santa Cruz. The fuel is coke, usually from Australia, coming from Newcastle, in New South Wales; but coke from Alabama and Utah also is used at Selby. The silicious ore is the rich stuff mined at Goldfield and Tonopah, in Nevada. On the day of my last visit to the Selby smelter, they were sampling a carload of ore from the Little Florence lease. This ore contained 15 to 25 oz. gold per ton and in hand specimens the dull yellow streak of very fine gold could be seen traversing the dark flinty quartz. Such stuff requires most careful sampling; the shipment is sampled by hand, one shovelful going to the sample, the next to the reject. The iron required to make a fusible slag is provided by scrap bought from junk-dealers in San Francisco. This scrap iron is bought for $9 per ton and it includes heterogeneous remnants of a curious kind, gathered from the ruins of the great conflagration that almost destroyed San Francisco in April 1906. In the strange assortment sold as flux to the Selby smelter are sewing machines, type-writers, old rifles, stoves, girders, electric motors, bolts, cables, spikes, frying pans, chains, pipe fittings, every form of iron likely to be used in a big city. I saw a whole stack of frying pans melted together by the fierce fire that followed the earthquake; there were lumps of agglomerated spikes, and chains that had lost their shape. The smelter will buy nothing longer than six feet, so any cable, channel iron, or the like, has to be cut before shipment to Selby. It would fall cross-wise in the furnace and prevent the charge from settling properly. Among the scrap piled in the smelter yard there were pieces of structural material such as channel iron and girders, and I noticed that in many cases the iron was melted with pieces of masonry so that they formed an artificial iron ore. Thus the ruins of San Francisco are used in the making of the lead from which the paint on the battleships is fabricated.

When once in the blast-furnace, the charge takes six hours to be smelted. The separation of lead from the matte and slag takes place within the furnace, the lead being drawn off through the Ahrents syphon-tap. The matte and slag run out into a rectangular settler or fore-hearth, which is on a truck, so that the slag being lighter overflows into the slag-pots, each of which holds two tons and is drawn to the water-front by a small locomotive, to be discharged into the Bay.

The matte is tapped from a lower level (of the fore-hearth) into a series of pans on trucks; after cooling, the matte is broken by sledge-hammers, then crushed, roasted, and returned to form part of a subsequent charge. When the copper accumulates in the matte beyond 16%, a further concentration is

effected by smelting a charge of matte, silicious ore, and limestone, so as to get a product containing from 45 to 55% copper. This is first roasted and then leached with the sulphuric acid liquor from the parting-room, the result being to make a bluestone (copper sulphate), which is sold to wheat-growers to kill 'rust' and to the Western Union Telegraph Co. for use in gravity cells. Some of the bluestone goes to Mexico to be employed as a chemical in the old patio process.

The Selby Smelter and National Lead Works.

The matte and the pyritic ores are roasted in Ropp furnaces, the invention of the former superintendent, Alfred Von Der Ropp, a Russian nobleman, now residing at Geneva, and as well known for his long and skillful management of this smelting establishment as he is affectionately remembered for his unfailing humor and courtesy. There are four of these roasting furnaces; three of them are 90 ft. long, and one of them is 150 ft. They are provided with a traveling mechanical rabble, operated by a cable that passes over a sheave at the upper end of the furnace, so that the rabble is outside of the furnace half the time, during which it is being cooled. This is one of the occasions when a nobleman got the best of the rabble.

Returning to the blast-furnace: the lead flows from the well into moulds and is cast into bars weighing 100 lb. apiece. These are taken on trucks to the refinery and there elevated to the upper floor.

Here are the liquating kettles. Liquation or eliquation is the process of separating metals by the difference in their melting points. The lead from the blast-furnace contains copper, antimony, and other metals, the presence of which interferes with its industrial utility; hence the necessity for liquation. There are four kettles for this purpose, arranged in pairs, each pair holding 60 tons. The impure lead is melted at a minimum temperature, about 710°F; at that temperature the copper comes to the surface in the form of dross, which also holds some antimony. A press is hung from a crane into the molten metal within the kettle and the dross is skimmed into this press, where, under a compression of 90 lb. per sq. in., the free lead flows back into the kettle, while the coppery dross (containing some antimony) remains. After 10 or 12 hours the dross will have been skimmed and the lead, now free from all but a trace of copper, is syphoned into a reverberatory called a 'softener,' where the temperature is raised and the remaining antimony driven off by volatilization and oxidation, chiefly the latter. The result of this operation is to put the antimony into the litharge that is skimmed from the surface of the molten lead; these skimmings are run through another smaller reverberatory with a charge of coke and galena and some of the copper dross from the liquating kettles; the result is a yield of copper matte and base bullion containing some of the antimony, the major part of which is collected in a slag assaying 35 to 40% antimony and 62 to 58% lead. This slag is re-smelted so as to yield an antimonial metal, which is sold to the Mixed Metals Co. at Omaha and elsewhere, to be used in making type metal, solder, babbitt, and other

In the Refinery. Reverberatory Furnace, Moulding-Kettle, and Moulds.

alloys of which antimony is a necessary constituent.

When the charge in the softening furnace is 'cooked,' that is, all the antimony, arsenic, and other impurities eliminated, the lead is tapped into desilverizing kettles, 3 ft. deep and 10 ft. diam. There are four of these and they hold 60 to 65 tons each. They are made of cast iron and are fired by oil (as are the other furnaces and kettles in the refinery building) brought from Bakersfield, California. The oil is pumped from the Union Oil Co.'s works, 1¼ miles away, to the tanks at the smelter. This oil is pumped from Bakersfield to the oil works, a distance of 300 miles. When you pass the Selby smelter as a passenger on the overland train and notice a most disagreeable sulphurous smell, don't blame the furnaces in the works you are passing, debit your discomfort to the oil refinery which is to windward (for the wind usually blows from the west) and so happens to reach the traveler just when the train is alongside the smelter. Blame Rockefeller, not Guggenheim. And, on second thought, don't blame even Rockefeller, for he has enough to his charge, including a $29,000,000 fine, for the Union Oil Co. is the one genuine competitor of the Standard Oil.

In the desilverizing-kettles, the temperature is raised to a point where a slab of zinc melts readily in the liquid lead; this is at 840°F. The zinc unites with, and collects, the silver. This is the old Parkes process. Sufficient zinc is added to desilverize the lead and as the zinc melts it is mixed, by a mechanical stirrer, into the bath of lead. The scum of zinc that begins to rise to the surface contains the silver, and gold also, which desert the lead for the zinc. It is a concentrating process. The lead as delivered into the kettle will contain 255 oz. silver and 15 oz. gold; the zinc scum, after being pressed, carries 3000 to 3500 oz. doré, this last being the smelterman's term for the two precious metals when mixed in unrefined bar. Literally, it means golden. Any copper remaining over from the preceding treatment is also collected in this zinc scum. The scum is squeezed in a Howard press so as to extract any uncombined lead. The pressing machine is lowered by a crane into the metal bath and when the press has acquired the temperature of the lead, the scum is ladled into the press. Formerly it was the practice to remove the scum and liquate it, but this has been obviated by the introduction of the press, which was invented by W. H. Howard, formerly at Pueblo and now at the Garfield smelter, in Utah. After being pressed, the scum contains 22 to 24% zinc, 10% precious metals, 3% copper, the rest being lead. The scum looks like the native silver, slightly tarnished, to be seen in mines, as in the Mollie Gibson at Aspen. The molten lead in the kettle resembles mercury, though it is less mirror-like and of lighter lustre. The final scum on the surface of the lead is collected by a wooden rake (which chars, but does not burn) and is lifted out by a flat ladle.

The lead is now free from gold and silver, but still contains some zinc, say 0.5%; it is syphoned to a reverberatory furnace on the ground-floor. This syphoning of molten metal is interesting. It is done by means of a 2½-in. iron pipe bent into U shape with one leg longer than the other. This bent pipe is laid in the bath of lead (within the desilverizing-kettle) until both have the same temperature; then the stop-cock at the lower end is opened and hot lead fills the syphon; the stop-cock is closed; two workmen manipulate the syphon (now full of lead) with tongs and hooked rods so as to get the syphon out of the bath without breaking the column, keeping the end of the short leg within the bath; when the syphon is finally put in place, the stop-cock is opened and the lead runs into the furnace below.

This furnace has a capacity of 70 tons. Here the lead is subjected to an oxidizing heat whereby all the remaining zinc is driven off, partly by volatilization and partly by collection as oxide in the litharge that is formed; this litharge is skimmed and resmelted in the blast-furnace.

Next the lead is tapped into the moulding-kettle, which holds 60 tons, and serves the purpose of maintaining the metal at a suitable temperature while it is being tapped—by a syphon again, but a much smaller one—into 50 moulds, set in three-quarters circle. Each of these moulds yields a pig weighing 100 pounds. As thus refined, the lead is taken to the white lead plant.

But before tracing the conversion of the metal into paint, we must return for a moment to the treatment of the by-products of the refinery. The zinc scum (from the desilverizing process) containing the gold and silver is placed in graphite retorts, to which condensers are fitted. By this process of distillation, the zinc is collected in metallic form, while the precious metals remain in a highly concentrated lead running 4000 to 6000 doré. This rich product goes to the cupelling furnace, where the lead is converted into litharge (which is sent to the blast-furnace), while the doré bar is reserved for the parting-plant. Here the silver is separated by being dissolved in strong sulphuric acid, the resulting silver sulphate being precipitated on copper, leaving a copper-sulphate solution (still containing free acid) that is used for leaching the high-grade matte, as previously related. The liquor from the condensation of the fume escaping from the parting-kettles has a cherry red or ox-blood color due to the presence of selenium, derived from selenides in the Tonopah and Goldfield ores. This gold and silver selenide is converted to a hydrogen selenide and is then reduced by the action of the sulphur dioxide, generated by the solution of the silver in sulphuric acid. The gold remains in the dissolving-kettle as a brown powder; this is washed thoroughly, and then melted in graphite crucibles, to be sent to the mint at San Francisco. The silver, precipitated on the copper, is washed, pressed into cakes, melted in a small reverberatory, and cast into bullion bars. The silver bullion is put in a vault while still hot, as also is the gold. When placed in orderly array within this vault, these beautiful bars of precious metal impress the visitor as tokens of the wealth of Idaho and Nevada, the two contributory States. The silver is sold to the various United States mints, but most of it is exported to Hongkong, for use in China.

We have traced the lead to the last stage of refine-

ment. In an adjacent building some of it is made into sheet-lead, for lining tanks exposed to acid liquors, and in another building at Selby the metal is made into shot of various sizes, put into cartridges, and made ready for those who shoot the ducks and geese so plentiful on the estuary of the Sacramento river and elsewhere in California. The lead is also used in making pipe for sanitary purposes and for

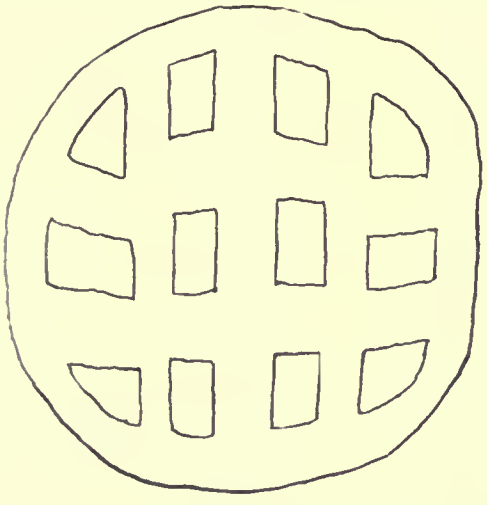

Fig. 4.

encasing underground electric wires. For such purposes it is being used in steadily growing quantities, for it admits of being twisted and bent as iron does not. But our interest at this time is its conversion into white lead to be used as a pigment. This is

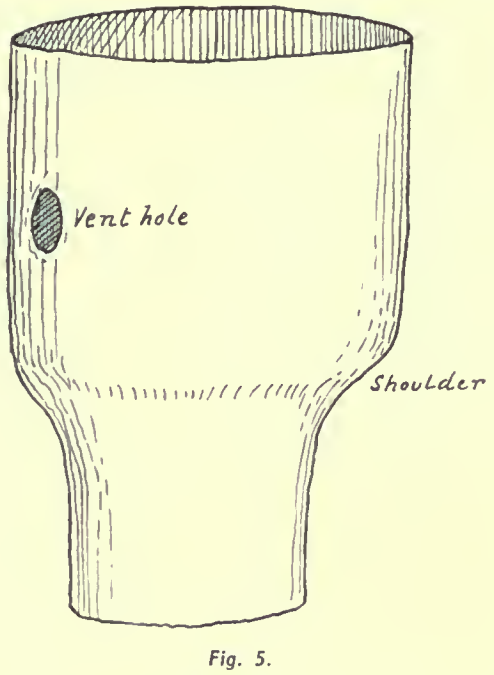

Fig. 5.

done at Selby in a plant alongside the refinery, from which we have seen the lead issue purified of all its other metallic associates.

Conversion of Metallic Lead Into White Lead.

Metallic lead in its purest form is used for making white lead; indeed, in the trade, 'corroding' lead is used as a synonym for purity. White lead results from the corrosion of metallic lead; the process involved is comparable to the rusting of iron, which yields a characteristically red product, just as the similar oxidation of lead gives a white substance. But the conversion of metallic lead into white lead is more than a process of oxidation, it involves both carbonic acid and water, so that it includes carbonization and hydration. White lead is a compound of lead carbonate and hydrated lead oxide, the formula being $Pb(OH)_2.2PbCO_3$. It is valuable as a pigment because it is dead white; any impurity in the original lead or any impurity introduced during the process of corrosion is apt to discolor the product; therefore, the manufacture of this substance demands the greatest care to eliminate every source of contamination prejudicial to a pure white.

The lead comes from the refinery in the form of pigs weighing 100 lb. apiece. The Selby plant manufactures 2500 tons of white lead per annum and this requires about 2100 tons of the 'blue lead,' as the pure metal is termed. Four or five tons of lead are

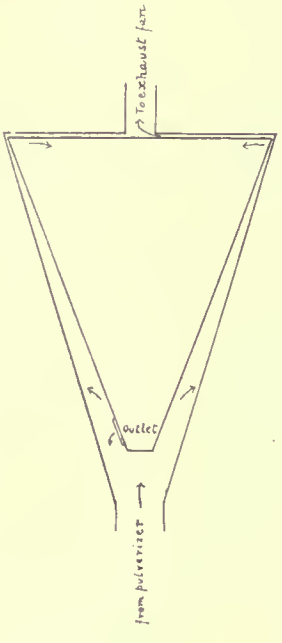

Fig. 6.

melted in a kettle. The molten metal runs out through a divided spout forming a steady double stream; this flows upon an endless chain made of a double series of moulds, each 6 in. wide, resembling waffle irons. The chain is long enough so that when the molten metal reaches the end, the lead has chilled and the perforated discs or 'buckles' fall in a pile ready to be transferred to the 'stacks'. The 'buckle' is a disc of lead $\frac{1}{8}$ in. thick, so perforated as to expose a large surface to chemical action, as shown by the accompanying sketch (Fig 4).

A 'stack' is a series of earthenware pots holding the blue lead while it is being converted into white lead. The pots are arranged in 9 tiers separated by layers of tan, the whole structure occupying a space 20 ft. square, to a height of 20 ft., within a wooden building, arranged in suitable partitions, the sides of which are built up or taken down, board by board, as circumstances require. In the pots the lead is placed so as to be exposed to the corrosive effects of acetic acid. The acetic acid comes from New York; it is made from lime acetate. Wine vinegar might

be obtained in California, of course, but it is too expensive for the purpose. Each pot is (as shown in Fig. 5) 11 in. high, the upper portion being 7 in. diam. and the lower 4½. The pots are made by the Steiger Pottery Co. at Baden, on the southern outskirts of San Francisco. The lower part is filled with acid; the shoulder, formed where the pot widens, carries the buckles, which are thus exposed to the fume without actual contact with the acid itself. If the lead were immersed in the acetic acid, it would be dissolved completely without forming white lead.

In building a 'stack', first a layer, 2 ft. thick, of 'spent tan' is laid down. This is the tan bark discarded from a tannery after all the tannin has been extracted. The tan used at Selby comes from Benicia. On this bed of tan a layer of pots is arranged in 27 rows of 27 each, or 729 altogether. The lower portion—4 in. deep—of each pot is filled with a pint of acetic acid; then the buckles are placed on the shoulder; there are 17 of them, weighing 15 to 18 lb. to each pot. In order to expose a maximum surface to the vapor, the buckles are not laid flat, but are crumpled. On the top of the tier of pots, now filled with lead and acid, separately, the workmen place boards, overlapping so that every crack between any two of them is covered by another board. The purpose is to prevent the tan on the floor above from falling through chinks into the pots of the tier underneath, for this would spoil the white lead. Thus tier after tier is built, the succession of tan, pots, and boards being repeated 9 times. On the top, as on the bottom, a layer of two feet of tan is packed solidly to exclude the air, which if admitted would hinder the regulation of the draft required for slow combustion.

It takes 3 to 4 days to build, and as long to take down, a stack. The treatment requires 100 days of undisturbed chemical action. In the interval, nothing is done save the regulation of the ventilation. Each tier has a ventilating flue, 4 in. square inside and made of redwood. This flue leads to the top of the stack, where there is a valve, so that the temperature may be controlled, just like a furnace, which a stack really is, only on a very low scale of temperature, namely, 170 to 175° F. This temperature is maintained during 100 days and the success of the operation depends upon the maintenance of an equable warmth. If too hot, the acid evaporates rapidly and the lead escapes corrosion; if too cold, the process is too slow and time is wasted. About 50 tons of blue lead is put in each stack and this yields the quantity of white lead indicated by the formula. Of the original lead, 75 to 90% is corroded.

The method in use at the Selby works is the old Dutch process, which has been in use for at least 500 years. Formerly, that is, up to 30 years ago, manure was used, instead of tan. The manure had to be renewed at each operation, but the tan bark is employed repeatedly, only 20% of fresh tan being added each time. When the tan arrives it is red; after use it is black, for it becomes charred. The tan serves as a fuel that has the quality of burning extremely slowly and thus of yielding a low temperature for a lengthened period. The tan ferments when moistened with water; this fermentation is, in effect, combustion, and by it the water is turned into steam, heating the acid and accelerating chemical action. In decomposing—by oxidation—the tan, which is a form of carbon, throws off carbon dioxide. This and the acetic acid vapor produced by the action of the heat on the acid, attack the lead and yield a compound of lead carbonate and hydrated lead oxide, that is, white lead.

The chemical changes are expressed by the following formulas:

1. Lead oxide is formed, thus:

$$Pb+O=PbO$$

2. Hydrated lead oxide is formed:

$$Pb+H_2O+O=Pb(OH)_2$$

3. Lead oxide in presence of acetic acid (abbreviated symbol, $Ac=HC_2H_3O_2$) yields lead acetate and water, thus:

$$PbO+2HAc=PbAc_2+H_2O$$

4. Lead acetate and hydrated lead oxide combine, forming a basic acetate:

$$PbAc_2+Pb(OH)_2=PbAc_2.Pb(OH)_2$$

5. The basic lead acetate, $PbAc_2.2Pb(OH)_2$, reacts with carbonic acid gas in the presence of steam so as to form white lead, $Pb(OH)_2.2PbCO_3$, neutral lead acetate, $PbAc_2$, and water. These reactions cannot be expressed accurately by any known formula.

Thus in the final stage, the interchange of atoms produces the molecules necessary to continue the reaction. This explains why a very small quantity of acetic acid suffices to corrode a relatively large quantity of metallic lead. Only 0.3% acetic acid is needed, that is, 0.3 lb. acid will corrode 100 lb. lead, while if the reaction were a direct conversion from one substance into another there would be required 120 parts of acid to 207 parts of lead. The re-agents necessary in large quantity are CO_2 and H_2O, that is, tan and steam, both being produced from the moistened tan.

For a week or ten days the valves of the flues are kept open so as to create a draft and accelerate the combustion of the tan. Hot steam escapes from the top of the flues and is visible on a cool day. When uncovered the buckles are seen to have been changed from a blue metal to a white earthy substance, and when examined it is seen that the change has proceeded to a varying degree: most of the buckles are corroded thoroughly, while others retain a thin nucleus of metallic lead.

The next operation is to separate the corrode from the uncorroded lead and grind it, to be ready for use as a white paint. When the chemical action in the 'stack' is completed, the top boards and uppermost layer of tan are removed. The pots are picked up by hand and (the acid having all evaporated) their contents are emptied into wheelbarrows, in which they are taken to a hopper, whence a bucket-elevator lifts the white residue to the top of the grinding-mill. The elevator discharges into a large revolving screen, called the 'rumbler', which resembles the trommel used in ore-milling. By the attrition to which it is subjected in this revolving screen, the white corrode is shattered, while the remnants of blue lead that have survived corrosion are flattened. The white

lead goes through four or five of these hexagonal revolving screens of increasing fineness, gradating from ¼-inch apertures to the size of a pin-head, that is, one-fortieth of an inch. Besides the screening, the corrode is subjected to reduction by two pairs of rolls. In this process also the bits of blue lead are flattened and extended, while the white lead becomes subdivided by breaking until it is pulverized. This facilitates the separation of the one product from the other, the blue lead going back into the yard, to be re-melted, and cast into buckles.

Finally, the white lead passes through the finest of the screens, having brass wire-cloth with $^1/_{40}$-in. holes. Brass is used because iron or steel would be rusted by the trace of acetic acid remaining in the corrode, and any rust, of course, would contaminate the white lead, which comes from the last screen looking like corn meal. Next it goes into a cylindrical bin and thence into a pulverizer, the effect of which is to throw the particles against each other so as to break them by the force of collision. On the top of the pulverizer stands an inverted cone, 20 ft. high, the bottom being 2 ft. diam. and the top 15 ft. Inside of this there is a second cone, open at the top and with an outlet at the bottom. The outer cone has a tight cover, the only opening being in the centre, where there is an escape through a pipe attached to a suction fan. (See Fig. 6.) As soon as the particles of white lead are fine enough to be carried in suspension they fly upward and outward between the two cones, which are 18 in. apart at the bottom and only half an inch apart at the top. The white-lead dust has to rise 20 ft. and fly horizontally 7 ft. before it reaches the outlet, in a stream only half an inch deep. If it is not sufficiently pulverized to be able to do thus, it falls back into the pulverizer for further comminution. This method of sizing in air is very different from, and much more effective than, the old way of separation in water. It is the invention of the superintendent of the white lead plant, which is the property of the National Lead Co. of California, while the smelter adjoining belongs to the Smelter Securities Corporation, a subsidiary of the American Smelting & Refining Company.

The fan above the cones is run at such a speed and the pulverizer is so regulated as to give a product that will pass through a silk cloth of 200 mesh or 40,000 apertures per square inch. Such a cloth will hold water for a while, that is the water will not break through until its surface tension is overcome. The silk comes from Grenoble, in France. From the fan the white lead passes to a cyclone collector, which is well named, for the draft makes a cyclone, the dust being blown into the top of a cylindrical tank with a conical bottom, so that the powdered white lead falls at the centre of the whirl, where a quiet eddy abates the centrifugal force. Thus it descends into a storage bin, ready to be packed dry or mixed with oil.

A Cruiser in Dry-dock at Mare Island Receiving a Coat of Paint.

To eliminate the last trace of acetic acid, the air that goes through the fan is first ozonized by being passed through a silent electric discharge of 5000 volts. The ozonized air has a decided smell, as of mountain air or the atmosphere after a thunder-storm. Ozone is a strong oxidizer and destroys any surviving particles of tan or acetate of lead. The excess of air from the pulverizer is laden with dust, that is, minute particles of white lead. To clear it, this dust-laden air is passed through 200 canvas bags, each 8 in. diam. and 40 ft. long, arranged in vertical series. These allow the air to escape through the canvas while retaining the dust, so that an extremely fine product is saved by this operation.

We have now followed the white lead to the bin underneath the cyclone collector. From this bin the product is put into a truck and then shoveled into a mixer, which is a revolving pan having a stirrer on one side. Here the proper quantity of linseed oil is added. The lead and the oil are mixed for 20 to 30

minutes. Then the valve in the centre of the pan is raised and the white lead passes into a receiver; this feeds the stones, where the white lead is ground with oil. The oil is refined linseed oil made from flaxseed grown in Idaho and Washington. The seed is crushed between rolls and then placed under a hydraulic press (6000 lb. per sq. in.), so that the natural oil is squeezed out. It is then refined by filtering and settling. The oil used at Selby is supplied by the Pacific Oil & Lead Co. of San Francisco, a branch of the American Linseed Oil Co. But if the white lead is to be packed dry, it is put into an ordinary flour barrel, which holds 800 lb. of white lead, as compared to 198 lb. of flour.

From the receiver the white lead drops into the eye or centre of a pair of oil-stones. These are French buhr-stones, the lower one revolving, while the upper is stationary, so that the lead has to pass between the two surfaces, which are pressed hard against each other. The white lead works its way to the edge of the stones and drops to the centre of another pair, the rotary motion again causing the product to travel from the centre to the edge, where it falls into a cooler, the white lead in the course of grinding having become warm (about 150°F). This cooler is a water-jacketed fixed brass pan with three revolving arms, which aerate the lead and move it to an outlet leading to a small hopper. The hopper empties into the kegs, as they are placed underneath by an operator. A keg 12 in. high and 10 in. diam. will contain 100 lb. lead in oil. The keg is filled while it is being weighed. White lead is sold in kegs of various sizes holding from 12½ to 300 lb. each. The kegs are made at St. Louis; the wood is oak. For this purpose the Californian oak is unsuitable, being too porous. The bungs are made of poplar, which is soft and does not split. A label is affixed with glue and this moisture causes the bung to expand so as to fill the aperture snugly. The label of the Selby works is in blue and gold, the colors of the University of California.

The plant is run by electricity, there being a separate motor for each part of the process. The current is supplied by the Bay Counties Power Co., from a generating station at Colgate, in Yuba county, 140 miles distant. The transmission of power involves crossing the Straits of Carquinez, a short distance above Selby, where the estuary of the Sacramento is 2750 ft. wide. Two towers carry the line; that on the north side of the Straits is 225 ft. high on a bluff 160 ft. above the water, and the one on the south side near Crockett, is 64 ft. high, at an altitude of 300 ft. The span, from tower to tower, is 4427 ft. long.

The smelting operations are under the direction of E. N. Engelhardt, as manager, with F. C. Newton, as assistant. The superintendent of the white lead plant is J. P. Neville. Thus a Russian, an American, and an Englishman unite in manufacturing the pigment, and just as the various substances required in the making of white lead come from localities widely separated, so the intelligence that applies them usefully is contributed by diverse nationalities.

From Selby the white lead is transported on a barge or steamer to the Navy Yard at Mare Island, which is less than a mile distant. Dry pigment is preferred for use at sea because oil renders it more subject to deterioration. Paint and oil are always placed in 'the eyes of the ship,' that is, the forepeak, right in the bow. Here there is a space that is useless for other purposes; it is fitted with shelves, tanks for linseed oil, and other ingredients. The fire-plug is always put in 'the bows', as a protection. But if the paint is to be used at once, the white lead already mixed with oil is purchased by the Bureau of Supplies & Accounts of the Navy Department, the price being 6 cents per pound. After arrival at the Navy Yard the white lead is mixed according to formula, the first coat contining considerably more lead than the last. This is done because lead is an excellent preservative against the weather and gives a good body for the first coat; if it were used in the final coat without a large proportion of white zinc, the surface of paint would soon acquire a dirty yellow hue. The following are the official specifications for the white lead purchased by the Navy Department.

SPECIFICATIONS FOR WHITE LEAD,

ISSUED BY THE

BUREAU OF SUPPLIES AND ACCOUNTS, NAVY DEPARTMENT,
OCTOBER, 1902.

SUPERSEDING SPECIFICATIONS ISSUED JANUARY, 1901.

Must be of the best quality, finely ground in pure well-settled raw linseed oil; must be of maximum whiteness; must work freely under the brush, and not be crystalline in structure nor deficient in density and opacity; must not contain more than 0.5 per cent of moisture, and as best commercial grades of white lead contain acetates equivalent to less than one-tenth of 1 per cent of glacial acetic acid, under no circumstances will white lead be accepted which contains acetate in excess of fifteen one-hundredths of 1 per cent of glacial acetic acid. Dry pigments must contain at least 98 per cent of hydrate carbonate of lead. Its working under the brush, maximum whiteness, body, and covering qualities to be determined by practical test.

GENERAL PAINT SPECIFICATIONS.

The pigment must be of the best quality, finely ground in pure well-settled linseed oil (unless otherwise specified) to a medium stiff paste which will break up readily in thinning, and must be free from barytes or other adulterants. The shade, fineness, and tone must in each case be in strict accordance with samples to be seen upon application to the general storekeeper.

Packing.—In all cases where paints, etc., are purchased in *metal* packages they are to be boxed in quantities of 100 pounds each; the cases to be made of ⅞-inch new pine, planed on the outside. Tin pails or cans (commercial packages) of 12½, 25, and 50 pounds are to be provided with bails.

It may be mentioned that each vessel has a certain allowance of paint given her every six months. The flanges of piping for steam, exhaust, ventilation, fresh water, and salt water, etc., all have to be painted with different colors, for easy identification. To suggest the quantity of lead consumed, it may be stated that an ordinary 30-ft. racing cutter, if painted for service, would require 150 lb. of paint. Just previous to a race, every particle of this is scraped from the boat, thus removing what would be equal to the weight of an extra man.

Zinc white is mixed with the lead as a preservative. Zinc white, or zinc oxide, is obtained by a process, the essentials of which were worked out by Samuel Wetherill in 1851; this consists in mixing the roasted ore with fuel (anthracite or coke), and bedding it 3 or 4 ft. thick upon a hearth made of perforated cast-iron plates. The furnace door is closed and cold air blown under the grate. The zinc is volatilized as metal, but immediately oxidizes to a fume, which is collected from the smoke by passing it through muslin bags. The fume so collected requires to be subsequently refined. Zinc white of pure grade is also made in one operation by distilling metallic zinc, or commercial spelter, placed in fire-clay retorts on the hearth of a reverberatory furnace, the light flaky oxide being readily carried off in the draft, and caught in collecting chambers of large dimensions. Another method, employed in France, is to expose metallic zinc to the action of superheated steam. Zinc oxide is formed, with the evolution of hydrogen, which may be mixed with carburetted gases to form an illuminating gas of high heating power. The great advantage of zinc white over white lead is that sulphur gases in the atmosphere will not discolor it, whereas with white lead a black lead sulphide is formed.

The drying of paints, varnishes, and oils means the oxidation of the medium with which they are mixed by means of some substance that will readily yield up oxygen, such as lead oxide (litharge) or manganese dioxide. Boiled linseed oil is commonly employed for this purpose, it having been boiled with one or the other of the above-named substances, whereby a portion of the oil is oxidized, and an amount of the oxidizing agent is dissolved and slowly continues the reaction in the oil. The effect of oxidation of the oil is to convert it into a permanent leathery material, which resists the action of the weather. It is this behavoir of linseed oil in the presence of a 'drier' or oxidizer that makes it suitable as a medium for spreading pigments upon wood and iron. Turpentine

Photograph by Turrill & Miller.

The Cruiser California in the Bay of San Francisco.

also oxidizes readily, and does not dissolve mineral substances, nor react with them chemically, but it is a solvent for the leathery product of oxidation of boiled linseed oil, and it also mixes with the oil, which it will not do with water or most liquids. Hence it is useful as a 'thinner' for paints, without impairing their quality, or checking their rate of drying.

The following are the instructions issued by the Navy Department relative to the painting of vessels:

INSTRUCTIONS RELATIVE TO PAINTING NAVAL VESSELS.

1. The quantity of the different paint materials given in the allowance is calculated on the number of square yards of surface to be painted and the number of coats to be applied. The number of square yards of painting surface for different paints is to be inserted in table at the time of the preparation of the allowance.

2. The quantity of oil and turpentine sufficient to mix a given amount of paint varies. If the paint is newly manufactured it will require less, and if there be a high temperature it will also require less, but the quantities given in the formulas may be considered a fair proportion, and such as will insure good drying.

3. Paint should be used as soon as it is mixed, and therefore should not be prepared in larger quantities than may be required for the work in hand. The drying qualities of all paints are injured if kept mixed in store-rooms for any considerable time. Surplus mixed paint should be carefully protected from the air, and used on the first opportunity, with a little turpentine added.

4. The surface of the work to be painted should be thoroughly cleaned and dry before the paint is applied.

5. Brushes after being used should be rubbed out and immediately placed in water and kept there until required again.

6. In painting all pipes aboard the vessel, the standard colors for piping as issued by the Bureau is to be adhered to for the different piping systems.

7. In the preparation of the allowance list of paints, additional colors and paints will be allowed for the painting of such articles and fixtures as would not be coated by any of the formulas hereafter given.

WHITE PAINT FOR OUTSIDE WORK.

Formula for mixing 1 gallon.

No. 1.

White lead in oil	pounds	7
White zinc in oil	pounds	7
Raw linseed oil	gallon	½
Turpentine	gills	2
Japan drier	gill	1

No. 2.

White lead in oil	pounds	5
White zinc in oil	pounds	9
Raw linseed oil	pints	3
Turpentine	gills	4
Japan drier	gill	1

This paint is to be applied to all work exposed to the weather, including outside of hull from load water line to rail; inside of waist; under break of forecastle and poop decks; and on the inside and outside of boats.

When the paint is in such condition as to require two coats, formula No. 1, as given above, should be used for the first coat, and formula No. 2 for the second coat. When only one coat is required, formula No. 2 should be used.

WHITE PAINT FOR INSIDE WORK.

Formula for mixing 1 gallon.

White lead in oil	pounds	7
White zinc in oil	pounds	7
Raw linseed oil	gallon	¼
Turpentine	gallon	¼
Japan drier	gill	1

This paint is used for painting crew's spaces, store-rooms, magazines, and dynamo-rooms, inside pilot-house, etc.

If old work is in good condition one coat is sufficient; if in bad, two coats should be applied.

FLAT WHITE

Formula for mixing 1 gallon.

No. 1.—For officers' quarters (white).

French white zinc	pounds	8
White lead	pounds	9
Turpentine	pints	3
Raw linseed oil	gill	1
Japan drier	gill	½

No. 2.—For officers' quarters (flat white).

French zinc	pounds	17
Turpentine	pints	3
Japan drier	gill	½

When the paint is in bad condition, having turned yellow or worn with age, it should be given one coat of white paint as per formula No. 1, then one coat as per formula No. 2 (flat white). If the work is in fair condition and only requires one coat of paint, formula No. 2 (flat white) should always be used. Formula No. 2 should be mixed as above in the afternoon, run through a seive to get out all lumps, skins, etc., top of vessel covered and placed aside until next morning, when all oil or liquid found floating on top of paint should be dipped off. If the paint should be found too thick, after stirring, to work free and spread well under the brush, a small quantity of clear spirits of turpentine should be added.

The quantity of different paints required to cover 100 square yards of surface one coat is as follows:

Weather work, white	gallons	3¼
Inside work, white	gallons	2½
Flat white	gallons	1¾

And thus finally we have followed the white lead from the ore broken in the mine in northern Idaho to the Navy Yard at Mare Island, where it is laid upon the sides of the battleship. But one more agent is necessary to finish this highly complex technical process; that agent is the sunlight of California. Navy men will tell you that the painting of vessels in the ports of Puget Sound is hindered by the dampness of the climate and that the sulphurous smoke of other localities will blacken the fresh paint. At Mare Island the painting proceeds under most favorable conditions, for the air is pure and sunny, so that the paint dries without hindrance. Thus many lands and many States contributed to the manufacture of the paint that not only decorates the battleship but also preserves its steel structure from the corrosive effects of wind and weather. We have seen that some one ingredient or device has come from France, Australia, New York, Missouri, Alabama, Washington, Idaho, Nevada, and California, but the final touch was given by the warm pure sunlight of California.

A simple calorimeter has been constructed by Charles Féry for determining the calorific power of gases and liquids. The combustion is effected at the base of a glass chimney, the top of which supports a nickel plate pierced with a number of holes. The air necessary for combustion passes down a similar chimney, which is connected at its base with the former. The two junctions of a constantan-copper thermo-circuit are placed at the tops of the chimneys, and the electromotive force in the circuit is exactly proportional to the calorific power of the combustible and to the volume consumed in unit time.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Box-rise is a name given in Western Australia to a timbered raise. Such raises are by law required to be timbered, regardless of the character of the ground, when they are steeper than 30° and higher than 30 feet.

Lubricating oil that low temperatures will not cause to thicken, may be made, according to Paul S. Baker, by mixing graphite with cylinder oil until it is of the consistence of paste, and then thinning up with kerosene until it will flow. This is said to remain fluid even at temperatures as low as 14° below zero.

Magnesite is a carbonate of magnesium resembling unglazed porcelain, being fine-grained and white. It has recently been introduced as a bleaching agent in the manufacture of paper from wood pulp, for which purpose it is said to be better and cheaper than chlorine. Tulare county, California, furnishes most of the magnesite used in this country.

Talc depends for its commercial value largely on its freedom from iron. The fibrous talc of Lawrence county, New York, is worth about $8.50 per short ton at tide-water. The best foreign varieties are worth $20 to $35 per ton. In Virginia the soapstone industry has assumed large proportions, the product being sold at $20 per ton. Pyrite often occurs in talc, but this will render it valueless, as it must be white for use in paper-making and similar industries.

Stockwork is an old name for a type of ore deposit which differs from well-defined veins in a complete absence of walls, and in presenting a more or less uniform decrease in metallic content from a central zone of relatively high enrichment outwardly on both sides into the country rock. It is most commonly seen in the cases of copper, tin, and lead deposits. The term has been erroneously employed in recent years throughout the Southwest to designate net-works of veinlets such as occur in some of the Nevada gold camps.

Emery is the trade name for an impure variety of corundum, containing iron as ferrous oxide (FeO), which imparts to it a dark color, usually grayish. Its hardness is slightly inferior to corundum, which fits it for certain uses where corundum would be less desirable. The name is wrongly applied at times to corundum from which the heavy iron minerals have not been separated in concentration. The largest deposits of emery are on the island of Naxos, in the Grecian archipelago, where it occurs in large masses, not requiring to be concentrated.

Fluorspar is of especial value in conjunction with fluxes for thinning the slags in the manufacture of steel, particularly in the open-hearth process. It is also employed for a like purpose in foundry practice. The higher grades, namely, the pure white or pale blue, are used in the manufacture of agate-ware and opalescent or milky glass. Western Kentucky and southern Illinois lead as domestic producers of fluorspar. The average prices for the American product f.o.b St. Louis are: ground, $9.93; lump, $5.64; and 'gravel,' $4.16.

Fuller's earth is used in clarifying oils and fats. It must be finely divided and free from such abrasive matter as might increase the wear of pump cylinders, pistons, and valves, and it must contain as much bleaching substance as is consistent with rapid filtration. It is observed that when the alumina exceeds one-fifth of the amount of the silica present the critical point is nearly reached, beyond which an increase in the densely bedding aluminous matter retards filtration, as the silica serves to maintain porosity. In the bleaching of cotton-seed oils, lards, and other organic oils or fats required for cooking, the presence of matter giving foreign flavors or odors constitutes a fatal objection. The value of ground fuller's earth is $14 to $17 per short ton.

Sulphur in coal occurs in three forms, namely, organic sulphur, which is held in some manner not perfectly understood; pyrite, either as 'scale,' that is, thin films on the joint-planes of the coal, or associated with layers of aluminous material, or in nodules called 'sulphur balls'; and, finally, as gypsum (lime sulphate), also occurring on the joint-planes, that is, the planes running at right angles to the bedding-planes of the coal vein. For coke-making low sulphur content is necessary, if the coke is to be used for smelting iron. In copper and lead smelting moderate amounts of sulphur in the coke do not introduce metallurgical difficulties, but increase the costs in various ways. Pyrite and the slaty impurities in coal may be removed by washing to a certain extent, and thus adapt a 'dirty' coal to the production of good coke.

Furnace temperatures may be measured without elaborate appliances and with great accuracy by means of Seger cones. These are slender cones several inches high, molded from some refractory material, such as clay, mixed with other substances in such proportions that cones having different melting points are obtained. A measurement of the high temperature is made by placing a number of the cones, having graduated melting points, in the furnace or kiln. Some of the cones may melt down, while others are unaffected. The one which shows incipient fusion will register very close to the temperature of the furnace. Pyrometers of various types are much used in high-temperature measurements, the thermo-electric pyrometer being, perhaps, the most popular in the United States. This instrument is based upon the principle of the thermo-electric couple. In it two dissimilar metallic conductors are joined and connected in electric circuit with a galvanometer. The couple is inserted into the furnace when an electric current is generated which produces a deflection of the galvanometer needle, the amount of which deflection depends on the temperature.

ADVICE TO MINING STUDENTS.

By J. H. Collins.

*It has been said that a student taking up practical work should put aside all he has learnt. This is not so; what he has learnt must be continually in use to interpret what he is learning, but he must from the first recognize the essential difference between laboratory and factory work. In a laboratory, accurate knowledge is essential, while the actual cost of operations in time and material is not considered for a moment. For instance, days of time and pounds in money are often spent to obtain a microscopic button of gold, which when weighed or measured is in many cases thrown away. In practical work, how different is the procedure! The man who can extract three-pence worth of gold at a cost of one penny is more valued and rightly so, than he who extracts six pence worth at the cost of a shilling. It is evident then that one of the very first things to be considered in practical work is the cost of the operations—cheapening of methods in time, material, and labor must be the constant effort of the operator, who as such has failed until he has produced something at a profit.

To show how important it is that you should view life as a school, I propose briefly to remind you how greatly our professional field has been extended within the experience of men now living and in active employment. Important new mining fields have been discovered and opened up in Europe, Asia, Africa, Australia, and America, while those already known have, with a few exceptions, continued to produce largely. The diamonds of Kimberley, the gold of Mysore, the Transvaal, Rhodesia, Queensland, West Australia, the Klondike, and many other regions are mostly new factors, while the demonetization of silver, even more than its increased production as a by-product, has so lowered its value that it can now hardly be accounted one of the precious metals. The supplies of lead and zinc, of copper and tin, have hitherto been sufficient to meet the enormously increased consumption without serious inconvenience, though the prices have fluctuated greatly. But the great supplies of alluvial tin from the East Indies, the enormous quantities of tin ore quarried in the Tasmanian stock-works, the considerable supplies from New South Wales, and the large and increasing shipments from Bolivia are all being readily absorbed, so that it really seems as if there must be a tin famine in the not distant future unless—which is hardly to be expected—there should be some substitute found for use in place of tin-plate.

But the United Kingdom is no longer the centre of production for these metals, as it was in not very distant times; production has been shifted to remote regions, though fortunately many of those regions are still within the British Empire. How great the shift has been in the cases of tin and copper is shown by the following figures. Half a century ago, the world's production of copper was estimated to be somewhere about 40,000 tons per annum, of which the west of England yielded rather more than one-third. Last year the world's production had increased to over 700,000 tons, but the west of England production had fallen to about 400 tons. In the year 1870, the world's production of tin was estimated at 20,000 tons, of which the west of England yielded about half. Last year the total production was 97,000 tons, of which the west of England only yielded something under 5000 tons. The production of coal and iron-ore has now reached enormous dimensions, and here too we no longer take the lead as we did for so long a time. And in addition to the mining of coal and the metals there has been a steadily growing production of such minerals as bauxite, kaolin, asbestos, barytes, lime phosphate, salt, etc., necessitating in some cases ingenious modifications of former methods of working.

In prospecting coal-beds, as also certain types of ore deposits, the diamond and calyx drills have been of the greatest service, and of late many ingenious contrivances for detecting deviations in the bore-holes themselves have been much in evidence. River dredging for gold and other minerals has been successfully carried out in many regions. Steam-shovels and other mechanical appliances have been employed successfully in open-cuts. In shaft-sinking in loose ground, the ingenious Poetsch freezing system has been of great value in several instances. As to the methods employed for breaking the ground, the chief changes have resulted from the use of machine-drills and high explosives. In 1868, I first saw Doering's machine-drill at work in Tincroft mine in Cornwall. It was not a success, for, being operated by steam, the workings were rendered almost unbearably hot: in fact, as long as steam was the motive power, the use of the machine-drill underground made very little progress either at home or abroad, and it is certain that if compressed air had not been introduced, boring machines would today play a small part in mining or tunneling. Once introduced, however, the immense value of the system for hard ground was fully recognized. For ground that can be driven for £6 per fathom or less there is even now little or no advantage in using machine-drills where even moderately skilled miners can be obtained, and the same may be said of stoping in other than very hard ground. For instance, six men at Wheal Kitty in St. Agnes have quite recently driven a full-sized cross-cut in fairly hard ground at the rate of 4 ft. per day. On the other hand, where ground is really hard, the saving of time and even of actual cost is often very great. We have no longer to drive adits as formerly at Hey Tor at £60 per fathom, or to sink shafts, as at North Roskear, at £1 per inch. Rock-drills and high explosives have changed all that. A further good effect of their employment has been the enlargement of the main drifts which together with cheap steel rails, has led to much improved underground transit. Ventilation also has been especially aided by the large amount of cool exhaust air set free by the machines. The greater number of machine-drills hitherto have been employed in sinking, raising, or driving, but there is a growing tendency to employ them in stoping also where the lodes or

*The Le Neve Foster lecture delivered to the students of the Royal School of Mines on March 19, 1908. Contributed by courtesy of the lecturer.

pay-streaks are sufficiently wide. Much improvement has shown itself in the planning of shafts; they are now usually rectangular rather than square, round, or oval, and either vertical or following the mean dip of the ore at a definite angle, without changes of direction or underlie.

Forty years ago much gunpowder was still used in the mines; today after many experiments with compressed powder, cotton-powder, and other such compounds, and after nitro-glycerine has been tried and given up because of its danger, such high explosives as dynamite, gelignite, and the like are almost universally used. They have not only become indispensable for breaking the ground, but they are also found to be much safer in use than the old black powder.

Great improvements have been effected in the machines used for compressing the air employed in using the machine-drills; compound engines, compressing the air in successive stages are now generally employed in the larger mines. Machine-drills operated by electricity have been tried in many places, but so far they can hardly be said to have held their own against the air-driven drills.

There have been great improvements in the engines used for winding during the past few years. It no longer takes 30 minutes or more to raise a kibble of stuff from the bottom of the deeper mines as it did within my remembrance; skips running between guides are now common; cages bringing the ore-wagons direct to the surface are employed in many mines; the men are commonly brought up from below in shaft-gigs or special skips, so that the man-engine, once so great a boon and so common in Cornwall, can now only be seen, so far as I know, in operation in the Levant mine. For modern winding, wire ropes are universally used, and are practically indispensable. Accidents from its use are indeed exceedingly rare. Mr. Morgan's traversing engine erected some years ago for hoisting from Williams's shaft at Dolcoath will soon be at work again, but so far no proposals seem to have been made for using this remarkable engine anywhere else. So numerous have been the problems connected with winding from deep mines that two volumes of the Transactions of the Institution of Mining and Metallurgy have been devoted to this subject alone. For signaling in shafts, the old 'knocker line' is still in use and has its advantages. Indicators for the guidance of the engine-man are, of course, placed in the engine-house in every case where men are raised, and in most other cases; over-winding is an extremely rare occurrence, such is the carefulness of the engine-men. The telephone was introduced in Wheal Eliza in Cornwall by Le Neve Foster many years ago for signaling from below, but it did not 'catch on.' However, it is used in many foreign mines for this purpose.

As yet, the deep mines of Cornwall as also those yielding really large quantities of water abroad — have been drained by a series of plunger and drawing lifts attached to set-offs from a vertically reciprocating and well balanced main-rod. And in most cases these are operated by the Cornish engine, which is a simple single-acting vertical condensing beam-engine, the expansion of the steam taking place within the cylinder. This combination is known as the Cornish pumping system, and no other system should have the name Cornish attached to it. In a few instances, a compound horizontal engine has been employed to work the main rod through angle-bobs with good effect as at the Basset Mines in Cornwall, and in several collieries in the north of England. Of late many attempts have been made to introduce centrifugal pumps operated by electricity for draining the mines and these have been successful in several large collieries. A certain measure of success too has attended these efforts at the Tywarnhaile mine in Cornwall, but it must be admitted that up to the present the system has made no notable progress in that region, though there have been several disastrous failures. I do not doubt that in the end electrically-driven pumps may reach success, even in vein-mining, but there are many difficulties to be overcome that the electrical engineers do not seem to have sufficiently considered. It is not so much the volume of water that calls for such serious consideration, nor even the depth from which much of it has to be raised, but the fact that the water comes in variable quantities and at varying depths; that it is often muddy, gritty, or corrosive. Often the pumps are liable to floodings and yet they must be fixtures capable of being started up to work after an interval while still under water. All these conditions are successfully met by the Cornish system. It must be admitted that so far they have not been met by any other system except at very great cost both in installation and working.

The steam boilers used in Cornwall are still mostly of the Cornish or Lancashire type, and work at comparatively low pressures. The number of these boilers working above 60 lb. per inch is not very great, and those working at 100 lb. or more could almost be counted on the fingers. But in foreign mines, multitubular boilers, portable or semi-portable, are used in a great many instances, particularly for winding, while a growing number of plants are worked by engines which consume 'suction gas.'

Many improvements have been introduced in the treatment of ores when they reach the surface. The first crushing is usually done by stone-breakers of the Blake or the gyratory type, followed in the case of gold, silver, and tin, by stamps of the Cornish, Colorado, California, or pneumatic type, the 'rows' being finally reduced by some form of fine pulverizer. At Dolcoath mine, powerful batteries of three types of stamps can be seen regularly at work on similar ore, and almost side by side. As regards economy, there does not seem to be much difference, but the preference is gradually given to the pneumatic stamp. Mechanical feeders have not yet been applied to the Cornish or Colorado stamps, but they are always employed for the California and the pneumatic stamps. Ores of copper, lead, and blende, after the first rough crushing, are usually further reduced by rolls or by Chilean mills, and then jigged. The finer sizes are dealt with pretty much as tin ores, only less elaborately. In dressing the crushed tin-ore, while buddles are still used at some stages, shaking tables of

the Wilfley or Buss type are extensively employed in many mines; in others, Frue or Luhrig vanners; hydraulic separators are mostly used to remove the slime before feeding the pulp to the tables, but in the case of the vanners, the slime is generally removed for separate treatment at a later stage. For the slime treatment of ores of tin, lead, copper, blende, etc., there is still nothing known that has proved itself better than the dead-frame, the ordinary round slime-table, or the Acme table. The old fashioned swinging rack for cleaning slime has practically disappeared, though it had some notable merits. There is still much room for improvement here, for it is not always possible, and it is always costly and inconvenient, to install a slime plant by the acre in a large tin mine, and less than that does not suffice even to recover a moiety of the valuable metal in the tailing.

Many forms of ore-treatment are on the borderline between mining and metallurgy, as, for instance, the chlorination and cyanidation of ores of gold and silver, and the wet-extraction methods for copper. In gold recovery, the general substitution of cyanide treatment for amalgamation, and the extensive introduction of the improved filter-press has, in great degree, removed the ancient dread of sliming; in fact, this is now directly aimed at in many mines, so that the modern tube-mill becomes more and more applicable every day.

Most tin-ores need calcination before they can be cleaned for market. In many of the smaller mines, the old reverberatory oven is still in use, but in the larger mines, the Brunton revolving calciner is always employed and is very satisfactory in its working. The calcination of tin-ores produces in some mines large quantities of 'arsenic soot' which, at one time valueless or worse, is now an important by-product. In Cornwall it is handled by the ton as freely as sand, and apparently with equal impunity.

An important by-product in some tin mines is wolfram, which at one time was merely regarded as a deleterious component of the dressed tin, but is now profitably extracted, in particular at Clitters United, East Pool, and South Crofty, by means of the Wetherill magnetic separator. In this machine, the powdered and thoroughly dried concentrate is carried slowly over electro-magnets on traversing belts. The magnets remove the slightly magnetic particles of wolfram, while the non-magnetic particles of cassiterite pass on and fall into a separate receptacle. The wolfram so separated in most cases still contains a considerable percentage of tin oxide. At the mines mentioned, this tin-wolfram product is 'pickled' with dilute acid (aided by jets of steam at East Pool) in order to remove certain highly magnetic iron oxide components which seriously interfere with the operation of the magnetic separator. A similar 'pickling' has long been recommended, and occasionally used on a commercial scale for the removal of copper from calcined tin ores.

The use of electricity is spreading in the Cornish mines, apart from the attempts to use it in pumping; at East Pool it has long been employed for surface traction, the mill being a mile or more away from the mine. At South Crofty, it is employed for operating the ore-breakers and the new stamp-mill, and the dressing plant generally; in several other mines it supplies power to work pulverizers, buddles, and other dressing machines, and in this direction, as also in electric lighting, there is a large field for extension.

At Tywarnhaile, and also at Dolcoath, the Elmore oil processes have been introduced for the concentration of low-grade copper ores. The wet pulp is mixed with oil and subjected to a partial vacuum by which means the ore-particles are floated up from the waste as a sort of mineral scum with much less loss than is the case by the method hitherto employed. Other flotation processes for saving zinc have been tested on a considerable scale in various parts of the world, but I do not know whether any of them can be said to have proved decidedly successful from a commercial point of view up to the present.

If the extensions of the mining field have been so great, those of metallurgy proper have been no less so. The enormous enlargements of the reverberatory and blast-furnaces, the many excellent mechanical roasting furnaces, the application of the Bessemer process in pyritic smelting and copper production brought about by Holloway and others, Nicholl & James's direct copper process, the great improvements in the production of electrolytic copper, nickel, aluminum, etc., the extended use of various forms of the electric furnace, all these have tended to revolutionize pyro-metallurgy by cheapening methods and extending the scale of working so that we now understand by a large smelting plant one like that at Washoe, which can deal effectively with 10,000 tons of ore per day; and in all this the alumni of the Royal School of Mines have borne a creditable part. There have, too, been many improvements effected in ventilation, sanitation, and safer working, partly brought about by the extension of Government inspection (and here too the Royal School of Mines has supplied some of the best inspectors), and partly resulting from the extension of technical education and the general march of knowledge, and all these have tended to the amelioration of the lot of the miner.

And now may I conclude this hasty survey of our field of work by offering you a few words of practical advice of an almost personal character. You who aspire to control men must be students of men, whether your subordinates, equals, or superiors. In particular you must know and appreciate good workmen when you meet them and must learn how to bring out the best even of the bad ones. Some workmen are jealous and will tell you nothing, or even tell you wrong; others will say what they think will please you for the moment, or what will give them the least trouble; others again, while quite willing to impart what they know, have no accurate command of language and you will have to carefully interpret their imperfectly expressed ideas for yourselves. In learning his work therefore, the aspirant must be modest—carefully avoid putting on airs—remembering that however much he knows, unless he knows what the workman knows of any particular operation and a little more, that workman will not recog-

nize any superiority in him. I would advise you, when you begin your post-graduate practieal work, to be neither too familiar nor too stand-offish with men who are acting under you, but who necessarily know more than you do of the immediate work. Again, if you should lower yourself by using the coarse language that is too eommon among workmen, they will not think better but worse of you for doing so. And there is no oeeasion for you to be forever taking pick, shovel, or wheelbarrow out of their hands, though it may be neeessary to do even this sometimes. But they will never think the worse of you if you are even more ready than they in an emergency to do any work that is dirty or disagreeable or dangerous. Then, as to your relations with those under whom you are placed. I need hardly say you should be always loyal and industrious; if your superior is of the right kind, be also zealous and stick to him till he earries you up with him. If, unfortunately, he is of the wrong sort, be loyal still, but get away from him to someone else as soon as you feel that there is no more to be learnt while under him.

You should be always trying to realize the differences in essential conditions. For instance, where ore is more plentiful than fuel or labor, you may waste ore to save fuel and labor, and the reverse. Again, except where time is of importanee, the steam-shovel is as much out of plaee in China or India, where men ean be got for 3d. per day, as the wheelbarrow in the United States where men get $4 per day. In foreign works, endeavor to utilize native labor as mueh as you can; it is always eheaper and generally less troublesome, but, of eourse, you must take the trouble to learn something of the native's language. When steam or machinery is employed, endeavor to keep it fully employed; where you have electricity at command generated by water-power, this, of course, is far less important.

Try to know some one branch of your profession as well as it ean be known; learn a little of everything else, so as to be in a position to appreciate the work of others and to know where to look for help in an emergeney. Be sociable and self respecting—not secretive or jealous, be a good comrade, take up a hobby by all means as a recreation outside your work, but avoid fads. Above all, don't expect others to fall in with them; and live 'the strenuous life.'

As to the spirit with which you should work, keep a due balanee between conservatism and radicalism. The man who never sees any line of improvement is of little value to an employer; on the other hand, he who is forever tinkering—'perfecting' as he ealls it—never arriving at a working conelusion, is even more unsatisfactory. And when you reach the position that gives you the power to 'scrap' maehinery or to introduce new proeesses and methods, be sure that the improvement aimed at is one that ean be fully realized, and that the scale of working is large enough to warrant the change before you enter on a revolution. Don't be too ready to despise old methods; they can very often be improved upon, but not until you have mastered their full meaning. "*Festina lente*" is a good motto, and if to industry and loyalty and perseverance you ean add a due sense of proportion, and that imagination which enables you to see things as they will be before they exist, your suceess is assured.

TREATMENT OF SULPHIDE ORES BY THE HUNTINGTON-HEBERLEIN PROCESS.

Contributed to the MINING AND SCIENTIFIC PRESS
By L. S AUSTIN.

In treating over 1000 tons of ore in a 50-ton plant by this process the loss in weight was 25%. There was a gain in gold of 7%, a loss of silver of 1.4%, lead of 8.5%, and of copper 1.4%. The ore, after roasting, contained 5.5% sulphur, and its analysis was much as follows: SiO_2 6, Fe 35, Cu 1, Zn 8.5, Pb 15%, and silver 21 oz. per ton.

The following figures for costs of roasting and pot-roasting may be given:

13 men @ $2.50 per day	$27.34
Foremen (part)	1.40
Fuel for roasting (slack coal) 6 tons @ $1.55	9.30
Power (estimated)	3.00
Lighting "	0.40
Repairs and supplies (estimated)	2.50
Treating 13 tons @ $1.02 per ton	$43.94

Comparing this result with that of the long-bedded hand-rabbled reverberatory roaster we have $2 for roasting and 60c. for briquetting, making a total of $2.60 per ton. Moreover, the H. & H. process costs $1.02, and gives a better product for smelting. In addition we may say that the losses in lead in reverberatory-furnace roasting will reach from 11 to 17 per cent.

Vanadium is obtained from lead vanadate ore with about 14% vanadic oxide and 50% lead by the Herrenschmidt method. The ore is smelted in a reverberatory furnaee with carbonate of sodium and coal. Metallic lead carrying all the silver is formed, together with a slag containing vanadates, aluminates, silieate of sodium, and oxide of iron. To render this slag soluble in water, it is melted in a reverberatory furnaee and, after melting, is blown with air until the vanadium is completely oxidized. The mass is then poured into boiling water to granulate it. After three leachings, the residues consist chiefly of alumina, silica, and oxide of iron containing not more than 2% of vanadic acid, that is 95% of the VO_3 in the ore is in solution. The vanadate solution is then evaporated to a syrupy consistence, and some sulphuric acid is added. About 90% of the vanadium is precipitated, and then the liquor is rendered alkaline and purified by filter-pressing, and the remainder extracted. In this way vanadic oxide containing 92 to 95% VO_3 is obtained.

The exports of fuel from the United Kingdom during the first quarter of 1908 totalled 5,059,222 tons of coal, coke, and patent fuel. This was an inerease over the shipments for a corresponding period last year, and the average price per ton is now 13s. 1d., showing a material advance over 12s. 2d., the average for last year. While the rate of increase in the exports is not fully maintained, the shipments of coal and coke continue to improve, and this branch of the mining industry is quite satisfactory.

MINE REPORTS.

BROKEN HILL SOUTH SILVER MINING CO., NEW SOUTH WALES.

The last report, issued in February, dealing with the half-year ending Dec. 31, 1907, gives gross results, and details of production, but is lacking in analysis of costs. The financial condition of the company is briefly stated by the directors as follows: "During the period under review £70,000 has been distributed among shareholders in dividends, £64,000 has been expended in plant and machinery, £10,000 has been written off plant accounts, additional expenditure on the new shaft amounting to £3374 has also been written off, and £2000 has been set aside for income tax. The net liquid assets amount to £46,132."

The total production of the mine for the six months was 111,009 tons, yielding an average of 15% lead, 12.3% zinc, and 5.04 oz. silver per ton. The bulk of this tonnage has come from the 725 and 825-ft. levels. The deepest level, at 970 ft., yielded over 2000 tons of ore, having a grade slightly higher than the general average of the mine. Development has been active throughout the property, reaching the respectable total of 7704 ft., of which one-half was on the bottom level. The report distinguishes between the full number of employees enrolled and the average daily attendance, the respective figures for surface and underground being 617 and 742 enrolled, and 503 and 653 checked off, making a total daily attendance of 1156. Taking the total laborers employed underground, it appears that the average output per man for the six months was only 0.94 ton per day. The costs per ton of crude ore were:

Mining	13s.	4.7d.	= $3.21
Development	3	0.4	= 0.73
Concentration	4	11.7	= 1.19
	£1 1s.	4.8d.	= $5.13

COBALT DISTRICT FOR 1907.

A summary of the operations in the Cobalt district has been prepared by Arthur A. Cole, mining engineer to the Temiskaming & Northern Ontario Railway Commission, and issued by the Commission. It shows a grand total output of silver for the year 1907 of approximately nine million ounces, estimated to have a value of $5,900,000. This was derived from 14,851 tons of ore, making $397 per ton. The tonnage increased from 5836 in 1906, with a value of $3,573,908, which indicates, according to a statement of the Ontario Bureau of Mines, not that the richness of the ore is decreasing, but that a larger proportion of low-grade ore is being shipped. Of the ores shipped 17.4% was treated in Canada and 81.47% in the United States, the remainder being taken in England. The Orford Copper Co. took practically all of that staying in Canada, effecting settlement on the basis of 94 to 80% of the silver, graduated in accordance with the silver content from ores carrying 4000 oz. or more down to 150 oz. or less per ton; purchaser to pay $30 to $10 per ton between the limits of 12 to 6% cobalt, no payment being made for cobalt when present in less amount than 6%, nor when the nickle content exceeded the cobalt; all ores to be shipped f.o.b. cars at Copper Cliff, Ontario. The schedule of the American Smelting & Refining Co. applied to ores from Cobalt, was as follows; for ores assaying under 1500 oz. per ton, 93% of the silver content at New York quotations as given by Handy & Harman to the Western Union Telegraph Co., 30 days after agreement on assays; $9 working charge per ton of 2000 lb. dry weight, plus ½c. per ton on each ounce of silver contained; arsenic above 5% penalized at the rate of 25c. per ton for each per cent; and an additional charge is made for each per cent of insoluble matter present above an amount equal to the percentage of iron present. The freight on ore from Cobalt to Perth Amboy, N. J., is $10.20 per ton. The mines of the district have now 74 steam plants, 2 gas-producer plants, and 51 compressor plants. There are four mills in operation and two custom mills nearing completion.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING CLAIM, INVALID JUDICIAL SALE.

Mere acquiescence by the debtor in an invalid judicial sale of his interest in a mining claim was held not to amount to an abandonment of the claim.

Crary *v.* Dye, 28 Sup. Co. Rep. 360, Feb., '08.

A senior locator may lose his right by failing to adverse.

Nash *v.* McNamara, (Nev.) 93 Pac. 405, Jan., '08.

MINING CLAIM—POSSESSION WITHOUT PATENT.

The right to a patent for a mining claim depends upon making the proper location, or upon having held possession during the period of the statute of limitation. So long as the statutory amount is expended each year upon the claim, the owner's right to exclusive possession and to extract and exhaust the ore is as complete as if he held a patent. The making of the location and the time for making it have no reference to the statute regulating the proceedings upon application for a patent.

Nash *v.* McNamara, (Nev.) 93 Pac. 405, Jan., '08.

MINING—EMINENT DOMAIN.

The exercise of the power of eminent domain cannot be invoked in aid of the business of mining for the benefit of the owner, for this is a purely private enterprise.

Sutter County *v.* Nicols, (Cal.) 93 Pac. 872, Jan. '08.

LOCATION OF CLAIM—DESCRIPTION, ETC.

The discoverer of a veln or lode may locate a claim by defining the boundaries thereof in the statutory manner, and by posting at the point of discovery a notice containing the name of the lode or claim, the name of the locator, the date of the location, the number of linear feet claimed in length along the course of the vein, with the width on each side of the center, and the general course of the vein or lode. Before the expiration of 90 days from the posting of notice of location, the locator shall sink a discovery shaft upon the claim of the depth of at least ten feet or its equivalent.

Nash *v.* McNamara, (Nev.) 93 Pac. 405, Jan., '08.

MINING CLAIM—POSSESSION THROUGH TAX-DEED.

A statute provided that mining claims, whether patented or entered for patent or not, should be assessable and taxable on account of producing gross proceeds, then and in that case the possession should be the subject of assessment, and in case such mining property should be sold for taxes levied, such sale should pass the title and right of possession to the purchaser. Under this statute a valid subsisting mining location was property distinct from the land itself and taxable; the right of possession of the land for mining purposes, and not the land itself, was the subject of taxation; that a tax deed under a sale conveyed the right of possession, but affected no interest of the United States; the tax deed upon its face was a valid instrument, and after the statutory period of limitation constituted a superior title to the claim of grantee from the person originally in possession.

Elder *v.* Wood, 28 Sup. Ct. Rep. 263, Jan., '08.

OIL LEASE—IMPLIED DUTY OF LESSEE.

Where an oil lease failed to specify the number of wells that should be sunk by the lessee, and did not require the sinking of offset wells to protect the land from drainage, yet it was held that from the nature of the contract an implied obligation rested upon the lessee to use reasonable diligence and care to develop and protect the property; and that he was bound to sink as many wells as the exercise of due diligence and care would suggest to an ordinarily prudent person engaged in the same undertaking under the same circumstances.

Guffey Petroleum Co. *v.* Jeff Chaison Townsite Co., (Tex. Civ. App.) 107 Southwest. 609, Jan., '08.

A NEW CHROME-STEEL CONE-HEAD.

The accompanying illustration shows a new method of making cone-heads for gyratory crushers, which is claimed by the manufacturers, the Chrome Steel Works, of Brooklyn, N. Y., to offer all the advantages familiar to users of chrome steel, together with greater strength and freedom from danger of breaking. The tapered ribs or corrugations are made from forged and rolled chrome steel, cut to required lengths, placed in a mold, and a soft steel backing then cast around rear projections from the ribs, interlocking and cast-welding the entire cone-head into one solid piece. The ribs are heated to a temperature just below

cherry red, before the molten steel is cast, and a perfect union with the ribs is effected. The casting is re-heated after removal from the mold, and then submerged in a special bath. This process hardens the chrome steel ribs, but does not affect the very mild crucible-steel backing, the latter carrying less than 0.25% carbon. The ribs, however, become so hard as to resist the action of a file. The Chrome Steel Works make these cone-heads to fit either the No. 6 Gates or the No. 5 McCully gyratory crushers. The new type of cone-head described is on the same principle as the chrome steel jaw plates with soft-steel backing, which have demonstrated their efficiency in practice. George W. Myers, 724 Kohl Bdg., San Francisco, is the Pacific Coast representative of the Chrome Steel Works.

PUBLICATIONS RECEIVED.

The Geological Survey has published the following bulletins: 'No. 327, Matanuska and Talkeetna Basins, Alaska,' by S. Paige and A. Knopf; 'No. 319, Controlling Factors of Artesian Flows,' by Myron L. Fuller; 'No. 336, Washing and Coking Tests of Coal, and Cupola Tests of Coke.'

CATALOGUES RECEIVED.

THE DENVER ENGINEERING WORKS CO. have issued Bulletin No. 1029, describing mine timber framing machines.

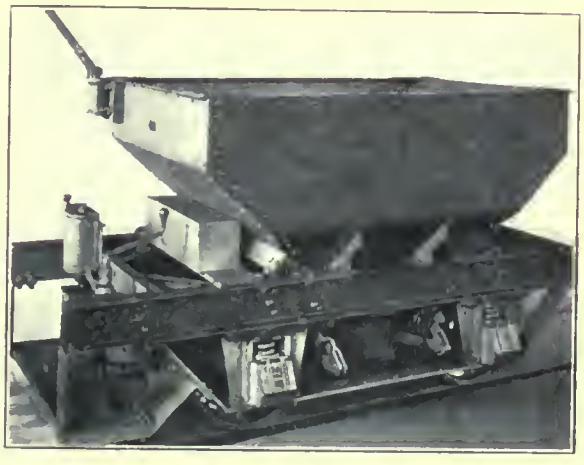
THE TRIPLEX ROLL CO., of Denver, Colorado, has issued Catalogue No. 2, describing a grinding machine, presenting several new features. The old system of rolls is modified by the insertion of a third and larger roll between the faces and at right angles to the rolls as ordinarily used. This feature of construction gives two grinding faces, and the faces are thus automatically kept true.

BOTTOM-DELIVERY ELECTRIC CHARGING CAR.

In the equipment of smelters and concentrators, which are today handling at good profits the low-grade material which ten years ago was looked upon as worthless, electricity is a most important element, and the electric charging car, which is used to convey the material to the furnaces, plays an important part in the work. After the ore has been received from the mines in railroad cars, crushed to the proper size and deposited in storage bins, the electric charging cars come into play. These are used to convey fuel, ore, and, in fact, all the raw material used and consumed around a smelting plant.

When a furnace is in blast it is kept so for an indefinite period. This requires cars and equipment made of the best material and workmanship possible to obtain in order to stand the rough usage. Also the car must be loaded and carried to its point of distribution rapidly, having ample power at all times for uninterrupted operation.

The accompanying illustration shows a type of car in use in a number of the largest smelters and concentrators,



known as the Atlas centre dump, swinging door design. The door swings outward, with the lever adjacent to the operator on the platform. The sides and ends of the car are of the steep-angle design, so that the material will not adhere, giving a clean delivery at all times. The framework and body are especially strong and well braced. The wheels are made of material to stand the hardest work, and are ground to insure maximum adhesion. The bearings are dust-proof, and waste-packed to insure protection and easy running. The brakes are of the standard street-car enclosed ratchet-handle type.

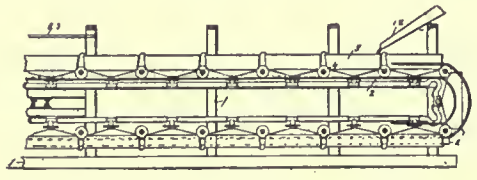
The electrical apparatus consists of a Westinghouse No. 64 motor, with type 'R' controller, enclosed resistance, circuit-breaker and cut-out switch, reversible spring-type trolley, having standard trolley wheel. The cut-out switch is operated from the platform, and when the operator leaves the platform the current is cut off. This is for safety and avoids accidents, particularly as these cars are operated under very close clearance conditions. The wiring is specially incased in water-tight conduits to protect it against gritty material, which might wear the insulation.

These cars are manufactured by the Atlas Car & Mfg. Co., Cleveland, Ohio; the electrical equipment by the Westinghouse Electric & Mfg. Co., Pittsburg, Pa. They are now in use at such well-known plants as the Garfield Smelting Co., Garfield, Utah; Utah Copper Co., Murray, Utah; Ohio Copper Co., Salt Lake City; Michigan Smelting Co., Houghton, Mich.; and the Anaconda Copper Co., Anaconda, Mont. The specifications of the car are: capacity, 5 tons; gauge, 36 in.; wheels, 21 in. diam.; length over all, 11 ft.; width, 5 ft.; height, from top of rail to top of car, 5 feet 6 inches.

MINING AND METALLURGICAL PATENTS.

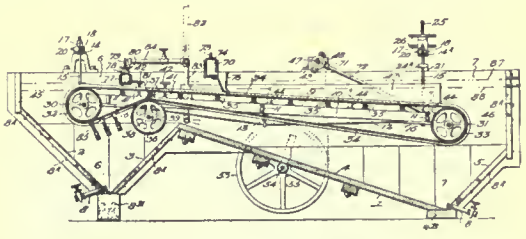
Specially Reported for the MINING AND SCIENTIFIC PRESS.

PROCESS FOR SEPARATING THE LIQUID FROM THE SOLID PORTIONS OF TREATED ORES.—No. 885,004. Edward P. Lynch, Mill Valley, California.



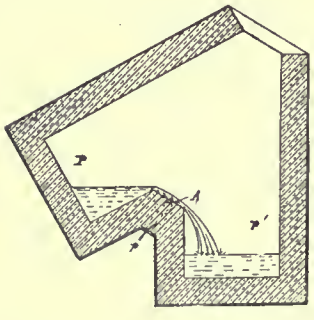
The herein described process of separating the liquid from the solid portions of treated ores and other substances, which consists in simultaneously subjecting a substantially thin body of the same, while in an extended form, to the action of suction from the bottom and decantation from the top.

SUBMERGED ORE-CONCENTRATOR.—No. 884,636. Charles L. Buckingham, Denver, Colo., assignor of one-half to Robert B. McCouney, Denver, Colorado.



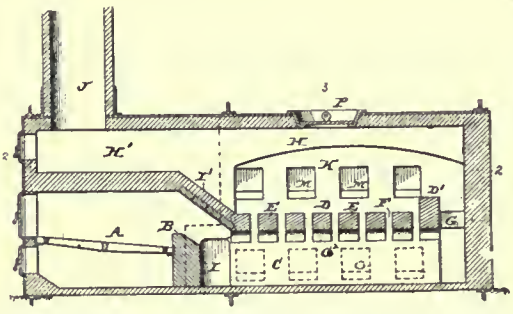
A submerged concentrator, comprising a tank adapted to contain a body of water, an inclined endless traveling belt concentrator suspended in said tank, means for adjustably raising and lowering said belt, an adjustable speed driving mechanism operatively connected to said endless belt concentrator and arranged to feed it continuously toward its highest or head end in said tank, a reciprocating movement mechanism connected to said concentrator and arranged to impart a rapid reciprocative vibratory movement to said concentrator, means for feeding ore pulp to said concentrator, splash boards on opposite sides of said belt adapted to confine the feeding ore to said belt, means for feeding clean water to said concentrator, and means for regulating the height of said body of water, to wholly or partially cover said concentrator.

PROCESS OF UTILIZING THE METALLOIDS IN CRUDE IRON FOR REDUCING METALLIC IRON.—No. 885,248. Henry D. Hibbard, Plainfield, New Jersey.



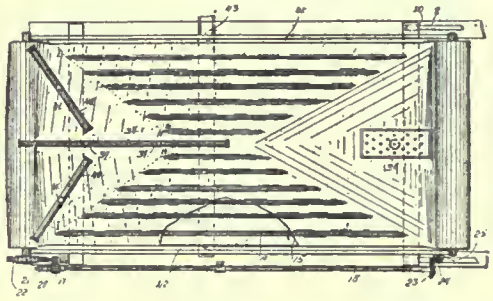
The mode herein described of utilizing the calorific power of the metalloids in crude iron in its reduction of iron from the oxid to the metallic state, said mode consisting in charging a vessel with a quantity of molten crude iron and adding thereto a quantity of oxid of iron, and mechanically agitating the mixture, the quantity of oxid of iron being so proportioned to the quantity of crude iron that the charge is maintained in molten condition by the oxidation of the metalloids in the crude iron without substantially affecting the carbon.

INCINERATING-FURNACE.—No. 885,380. John Ross, Philadelphia, Pennsylvania.



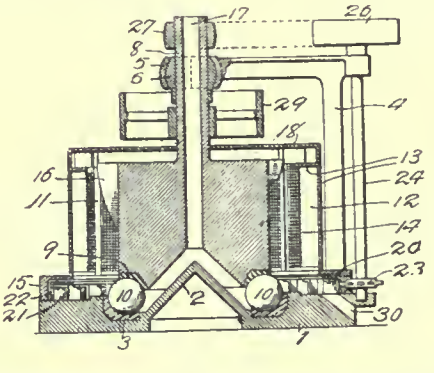
In an incinerating furnace, the combination of a grate, a lower flue leading therefrom through which the flame passes, an incinerating arch having openings through it arranged above the lower flue, an incinerating chamber immediately above the incinerating arch and connected with the lower flue at its end most distant from the grate, a chimney flue leading from the incinerating chamber to the chimney, a lateral incinerating chamber opening laterally from the incinerating chamber above the incinerating arch and provided with an incinerating arched floor having openings through it, flues for causing hot gases to pass under and then over the arched floor of the lateral chamber, and means for charging the furnace with garbage.

CONCENTRATING APPARATUS.—No. 885,692. James P. Evans and Randall P. Akins, Denver, Colorado.



A concentrator comprising a table or concentrating surface having a forwardly and centrally located depressed feed space, a centrally located longitudinally disposed apex extending rearwardly from the feed space, the top of the table being transversely inclined on opposite sides of the apex, said sides being provided with longitudinally disposed riffles arranged parallel to the apex, suitable means for feeding the material to be treated, to the forward portion thereof, and suitable means for supplying the table with wash water, substantially as described.

PULVERIZING-MILL.—No. 885,211. Levi D. York, Portsmouth, Ohio.



In a pulverizing mill, the combination of a driver, a shaft therefor, an annular chamber into which pulverized material falls, an annular conveyor in the chamber, a pinion engaging the conveyor, a pinion shaft, pulleys on the driver and pinion shafts, and a belt connecting the pulleys.

Editorial.

THE DECLINE in the price of silver is due to the diminished demand from India and the lessened consumption of metal in the arts. Since the beginning of the year London has shipped to India only half the amount that went out in the corresponding period of last year. China has been selling freely.

"IT'S WRONG, but it's business," was the excuse of a New York stock-broker named McIntyre, when called upon to explain his action in hypothecating securities deposited by customers in trust with his firm, which recently failed. The secretary of the Stock Exchange promptly issued a denial of any such custom, and stated that every member knew that such a practice was reprehensible. Meanwhile McIntyre had confessed that a large amount of securities deposited with his firm for transfer, or other purposes than as security for marginal transactions, had been used by the firm as collateral for loans. "It's wrong, but it's business," said he. And that is the motto of graft all over the country, from New York traction steals to San Francisco trolley briberies. It is wrong and it is theft.

THE ROBINSON mine, according to the annual report just issued, made an operating profit of £904,270, or $4,385,710, in 1907. The dividends amounted to £660,000, or $3,201,000, on a capital of £2,750,000. The gold produced was worth £1,277,198, or $6,194,410, so that the profit was 70 per cent. Thus the leading mine of the Transvaal remains the greatest gold mine in the world, greatness in a mine being measured by the profit yielded. This profit has been increased lately by the fact that the mine is now fully developed to its boundaries; the usual cost of development has been 75 cents. The Robinson is now undergoing exhaustion, without compensatory development. The Homestake crushed more ore and the Goldfield Consolidated produced more gold, but neither of them approached the Robinson in the dividends distributed to shareholders, and that is the primary purpose of digging a hole in the ground.

FUTURE PROSPECTS of profitable mining in India centre around the Mysore mine, which has found good ore after passing through a poor zone. This mine has enough ore to maintain the present rate of production for nearly five years and the profit assured represents 66 per cent of the market valuation. The deepest workings are now 3600 feet on the vein. The Champion Reef also is doing well, while the Nundydroog and Ooregum almost hold their own as regards dividends, despite a diminution of output. On the whole the history of the Kolar goldfield has been unexpectedly satisfactory,

the lodes have proved far more persistent than anticipated in the early stages of development, and the profits have been maintained much longer than financial critics expected. To John Taylor & Sons, as managers, the results are largely due, even though "a good bal makes a good cap'n"; it is delightful to credit so striking a success to so old a firm of engineers.

WE HAVE RECEIVED several enquiries regarding the Mining Exposition to be held in Madison Square Garden from May 25 to June 20. Mr. W. M. Porter is the originator of the enterprise and we are assured that it is not a scheme for selling mining stock but a legitimate and praiseworthy effort to educate the public in mining methods. There will be a fine display of minerals and machinery, besides a drilling contest.

Reports and Prospectuses.

OUR esteemed contemporary, *The Canadian Mining Journal*, asks whether it is right for a mining engineer to report upon a mine in which he is financially interested. The question is prompted by the fact that Mr. J. Parke Channing, vice-president of the Miami Copper Company and consulting engineer to the underwriting syndicate, made the report appearing in the prospectus recently issued. In several respects this was a model prospectus, but was it proper for the participating engineer to prepare the prospectus report? The same criticism holds true of the reports by Messrs. A. C. Beatty and O. B. Perry appearing in the Yukon Gold prospectus. Both these gentlemen are directors of the company and directly concerned in the outcome of the enterprise, even if they shared no responsibility in Mr. Lawson's attempt to extract money from simple people. Here we have a question worthy the consideration of professional men.

In the first place, none of the gentlemen mentioned can be charged with sailing under false colors, for in both prospectuses it is stated frankly enough what professional relation they bear to the companies whose properties they appraise in their reports. Obviously there is no desire to hide the fact either that Mr. Channing is under retainer to the Lewisohns or that Messrs. Beatty and Perry are in the employ of the Guggenheims. No one is told even inferentially that the opinions are those of unbiased experts. And yet the majority of those who subscribed for stock will have overlooked the relation between the engineer and the promoters, they will have bought shares on the supposition that the reports expressed the authoritative conclusions of men well fitted to give advice to the public. As a matter of fact, scarcely one of the intending speculators will have stopped to analyze the position. They will have been influenced as much by the reputation of the promoters as by that of the engineers; arguing that neither the Lewisohns nor Mr. Channing, neither the Guggenheims nor Messrs. Beatty and Perry, could afford to make themselves responsible for bad business. Moreover, even if an engineer be either financially or professionally associated with a promoter, does it necessarily follow that he cannot observe accurately, state facts truthfully, and arrive at a conclusion logically? Is not the first-rate engineer employed by Lewisohn or Guggenheim a better judge of mines than the average run of other men and is he not as likely to furnish a reliable estimate as any other fellow chosen by a putative purchaser of stock? Therefore, is it not rather finical to object to the use in a prospectus of a report made for the underwriting syndicate or the vendor company? Does the English company law prevent any complication of a similar kind? Is it not a fact that the reports printed in a London prospectus are the work of engineers paid by those interested in the disposal of stock and if the difference be that the engineers do not become directors until after allotment, does it make much difference as regards protection to the public or safeguarding of professional ethics?

To all of this we can reply simply and directly. Gratuitous advice is usually worth what it costs. A man who acts on the advice for which another is paid is apt to find himself playing the other fellow's game. The public loses in mining by speculating on the strength of data furnished by those whom it does not pay and who are in the pay of the promoter, whose business it is to sell something for more than it is worth. It is no aspersion on the honorable character of an engineer to say that we would rather take his advice when he is retained by us than when he is engaged by the man who is selling the mine to us; we would rather buy Miami on the report of Beatty, and we would consider it better business to purchase Yukon Gold on the report of Channing, simply because we might then get an opinion that was not crossed by conflicting interest. Of course, the ideal professional man would make the same report for the vendor as for the vendee; he would come to an identical conclusion as regards the worth of a mine whether he owned half of it himself or if it were owned by his worst enemy; he would not swerve in his appraisal whether he were paid his fee beforehand or the fee were contingent upon the sale of the mine after his report. But we do not live in an ideal world; engineers are human, promoters are predatory, the public is foolish. We live not in a dream-world but amid brutal realities, and the only means of escape from complications is by looking the facts fairly in the face. An engineer engaged by the owner of a mine is likely to emphasize the good points of it; an expert in the pay of a promoter is apt to state the favorable features of the new enterprise underwritten by his client. The average run of speculators (they love to think themselves investors) are usually losers in mines because they have no advice independent of those from whom they buy. Only too often they blame the engineer on whose report they bought, not realizing that such a report is the most favorable statement within the limits of truth and not a cold-blooded diagnosis disregarding the financial exigencies. The owner of a mine asks an engineer to examine it, the engineer gives a report based on the facts as he sees them, and he makes his report as favorable as circumstances permit, for is he not in the employ of his client? If the engineer

be engaged to examine the mine for a possible purchaser, he will look out for the weak features of the mine, will be alert to discover the reasons prompting the selling of it, being anxious to safeguard his client, and he will place his fingers on any factor likely to lessen the value of the property. It may be claimed that an upright man would make exactly the same report whether engaged by one side or the other; he might if appointed by a court of appraisal, but he is not so appointed; he is engaged to advise a man whose interest lies one way or the other in a business transaction. We grant that an engineer of absolute independence might assume the exactly impartial attitude of an official appraiser and he might refuse to deliver a report save on the understanding that it be accepted just as he choose to phrase it, and although paid by Guggenheim or Lewisohn he might write a report in which the weak points of a mine were as fully discussed as the stronger features—the uncertain price of copper emphasized, the difficulty of working frozen ground frankly stated! We do not say that such reports are never made. Occasionally the unfavorable features of an enterprise are brought down to the vanishing point and the engineer sees plain sailing ahead. This may have happened in the case of Miami or Yukon Gold. After all, the engineer who reports on a mine for a promoter is an advocate, truthful and honorable by every token, but engaged nevertheless to present the case in as favorable a light as he can in the interest of his client. He has not yet become quite as much an absurdity as the expert witness in mining litigation who under guise of giving technical testimony is really a scientific special pleader, committed to one side and expected to help that side to the utmost of his ability. On the whole, we believe that the recognition of the real position is best for the development of professional ethics and that make-believe is the worst enemy of progress in human affairs. And to make the situation plain, we say that it is well for the public to understand that when a report appears in a prospectus it represents a favorable opinion prepared by one who is in the employ of the company or syndicate that is offering stock for sale; the opinion is not necessarily unreliable nor untruthful, but the point is that it represents the most favorable conclusion possible with regard to the facts as stated in the interest of a seller.

It is not likely that the present practice in these matters will be changed suddenly, for who is to demand it? The buyers of shares are rarely able to unite in sending an engineer to examine a mine at the time of flotation, and promoters are hardly likely to give notice to whom it may concern that they have a deal in hand for organizing a company to work this or that mine, so that those likely to be interested may be ready to send a representative to examine the said mine. On the contrary, the position of the promoter is that of a man who has spent his time and money in ferreting out a good mine, and having found a prize he is willing to take part of his reward in cash from those who want to buy into it at an enhanced price, retaining the remainder for himself. As evidence of the character of the mine he furnishes a report prepared by an engineer in his employ, and if that engineer be a man of good reputation the report is likely to be substantially correct. If you think it is not, leave the stock alone; you are under no compulsion to buy. If you think well of it, join with some others in arranging for an independent examination. Honorable promoters will welcome such an investigation and it is cheaper than going ahead blindfold.

The engineer cannot keep himself wholly disentangled from the wiles of promotion, he cannot stand entirely aloof from the business world in which he moves, so it only remains for him to safeguard professional integrity by the utmost frankness in all his dealings. To that end, he should avoid taking a financial interest, share, or participation in the future profits of an enterprise to which he stands in an advisory capacity. If he does acquire, by purchase or bonus, such an interest, he must recognize the danger of self-deception and he must face the fact that men of sane judgment will doubt the trustworthiness of his opinion.

Conservative Finance.

OUR London correspondent makes complimentary reference to the conservative financial methods of the Mountain Copper Company, but we are able to correct an erroneous impression which he shared in common with many as to the motives leading to the reorganization in 1902. That was not done because of any embarrassment, immediate or prospective, resulting from the ascertained limitations of the size of the available orebodies, but as a convenient means of economically distributing accumulated funds in the way of a reduction of capital account. This was effected by organizing a new corporation, which became the assign of the old company, exchanging the original £5 shares for redeemable debentures of the new company having a face value of £4 each, in addition to a cash distribution of £1 per share. Since then, in 1905, a further distribution was made by the cash payment of £1 on each debenture, reducing the face value of each to £3. That makes a cash return to the shareholders of £500,000 in reimbursement on an original of £1,250,000, thus reducing capital account to £750,000. If a further £2 per debenture be paid, as likely will be done, the remaining £1 due per face value of debenture will, by the terms of incorporation, automatically become a share of the value of £1 in the new company. This new company issued nominal stock of £20 only, being barely sufficient to legally admit of incorporating a holding company with its board of directors. The debentures are secured by a trust, and the original shareholders are in the position of being debenture holders until such time as the original capital shall be written off to the level of £1, when the trust will be dissolved. All this was done merely as a means of avoiding the difficulty and expense attendant upon going into court each time that it should become desirable to reduce share capital by the distribution of an accumulated surplus.

Personal.

H. R. WAGNER is at Denver.

BEN. S. REVETT is at Seattle.

H. H. KNOX has gone to Siberia.

GILMOUR E. BROWN is in Bolivia.

H. F. LEFEVRE is at Reno, Nevada.

CHARLES M. MCNEILL is in New York.

F. T. BYRDE has returned to London from Egypt.

GEORGE A. SCHROTER is here, on his way from Mexico.

ARTHUR W JENKS was in San Francisco last Saturday.

J. H. ALLEN has returned to New York from the Caucasus.

ZERINA LANE has left San Francisco on his return to Australia.

C. H. MERRIAM, of Spokane, has been examining mines near Needles.

DAN F. O'BRIEN has left Manhattan and is now at Skookum, Nevada.

FRANK OLIVER is enjoying a short holiday at Santa Monica, California.

W. H. STAVER has returned from Ecuador and is now at Freeport, Illinois.

PERCY G. HOLMS has been appointed British consul at Guanajuato, Mexico.

EUGENE COSTE, of Toronto, has been examining the oil-fields of Chihuahua.

C. W. GILMAN is manager for the Nevada-California Co. at Lovelock, Nevada.

JOHN A. REID is returning from Triunfo by the *Curaçao*, arriving here next week.

GEORGE A. PACKARD has been to Round Mountain, Nevada, and is now at Los Angeles.

DAVID ATKINS, of DeGolia & Atkins, is examining mines in Sierra county, California.

GEORGE I. ADAMS has returned to Washington, after an absence of three years in Peru.

WILTON E. DARROW has returned to Sutter Creek after a short holiday in San Francisco.

FRANK W. OLDFIELD was here this week, on his way from British Columbia to Los Angeles.

F. L. PATTERSON is superintendent of the Esmeralda mine at San Felipe, in Oaxaca, Mexico.

O. A. KNOX succeeds A. E. HURLEY as manager for the Octave Mining Co., at Octave, Arizona.

WALTER G. PERKINS has returned to Ely, Nevada, from a visit to the Anaconda plant in Montana.

G. M. GOUYARD has been appointed consulting engineer to the Mexican Exploration & Mining Company.

ERNEST CRAIG, manager of the Last Chance mine, at Mogollon, New Mexico, will go to England this summer.

L. D. GODSHALL is managing director for the Arizona-Mexican Mining & Smelting Co., at Needles, California.

W. H. LINNEY, recently manager of the Nipissing mine, at Cobalt, has opened an office at 502 Hyde Block, Spokane.

J. BOWIE WILSON, formerly at Mt. Morgan, has opened an office as consulting engineer at Sydney, New South Wales.

F. N. FLYNN, manager of the La Rose and other mines at Cobalt, Ontario, has resigned and will return to Mt. Vernon, New York.

ROSS B. HOFFMANN and JOHN D. HOFFMANN announce their change of address to the First National Bank Bdg., at Oakland, California.

A. E. HURLEY, for eight years manager of the Octave mine and mill, near Congress Junction, Arizona, has resigned and has gone east for a vacation.

S. E. BRETHERTON, who has opened an office as consulting engineer at 532 Commercial St., San Francisco, retains his position as general manager for the Great Western Gold Co., in Shasta county, California.

OBITUARY.

R. F. MOSER, chief mechanical engineer of the Boston Consolidated Mining Co., died at Salt Lake on the 5th inst., as the result of an operation for appendicitis. The deceased drew the plans for the Cactus mill of the Newhouse Mines & Smelters Corporation, in Beaver county, Utah, and later that of the Boston Con., at Garfield, Utah.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Virtue Co. has resumed operations on its property at Portal, employing four men in two shifts.——The Consolidated will sink a two-compartment shaft to the copper orebodies recently uncovered in the Emerald. They will utilize the first 100 ft. of the single-compartment shaft in the Silver Plume.——The shaft of the Warren Realty & Development Co., below the Warren townsite, has reached a depth of over 700 ft. Last month a bonus of $250 was distributed among the employees on account of the great progress made in sinking.

MARICOPA COUNTY.

The Baltimore group of mines, in the Hassayampa district, has been sold to Lester Jackson, who proposes to run an adit to strike the vein at a depth of 400 ft. There are already several hundred feet of underground workings on this property.

MOHAVE COUNTY.

The new hoist of the Nighthawk is in place and the property is being unwatered.——The Southwest Gold & Copper Co. has been organized to take over and work a group of claims in Lost Basin, 70 miles north of Kingman.——The Idaho-Columbus mill is running steadily on ore from the Vanderbilt mine.——Several carloads of lumber were received this week and are being hauled out to the Tom Reed mines.——Howard Wells has taken a contract to sink a 100-ft. shaft on one of the claims of the Expansion group.

SANTA CRUZ COUNTY.

The cross-cut which the Globe Con. Copper Co. is driving from the Gem shaft to the Future vein is now in 885 ft., 50 of which is in ore assaying 18% iron, 14% sulphur, and 2% sulphide of copper.——The Gringo mill, five miles from Patagonia, was started last week. At present only five stamps are dropping, but an additional five have been ordered and will be started as soon as they are in place.——Strange as it may seem, Mexican miners are still washing gold from the gravel in Old Patagonia canyon, 12 miles southeast of Patagonia. They use the primitive board rocker and it is claimed they earn from $25 to $40 per month.

YAVAPAI COUNTY.

The Alvarado mine, five miles east of Congress Junction, is being put in condition and new mining and milling equipment installed. From the old shaft, which is 1100 ft. deep, some important drifts have been driven, and good ore uncovered. At a higher point a new shaft is being sunk, the depth now attained being 500 ft. For this work a new hoist was installed. The original mill had 10 stamps, to which 30 more have been added. Tube-mills are also being installed for fine-grinding preparatory to cyaniding. The ore contains gold, largely in association with iron sulphide. Charles Lynch, formerly of Gold Road, is metallurgist in charge.

The A. S. & R. Co. smelter management at El Paso, Tex., has announced a cut of 40% in treatment charges for Arizona ores, through its agent at Prescott; and at the same time the transportation rate on ores shipped from western Arizona points has been reduced from $11.05 to $5.50.

YUMA COUNTY.

The Colonial Co. expects to begin the production of mercury at their property 12 miles north of Quartzsite, within two weeks. The ore is treated for gold and silver after the mercury is extracted. The new furnace has a capacity of 30 tons per day.——S. Markwell & Son have purchased a half interest in the Hottentot group of claims 15 miles east of Parker. It is said the consideration was $75,000, and the agreement to do an immense amount of developing soon. The ore is reported to run 35% copper and $10 to $40 in gold.

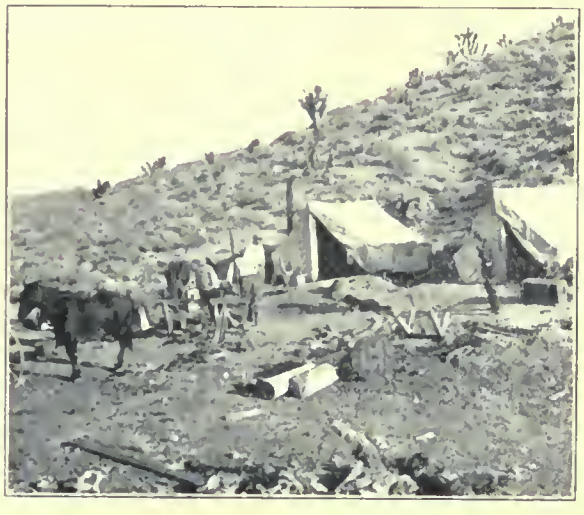
CALIFORNIA.

INYO COUNTY.

The Golden Gate has let a contract to George Stevens to drive their adit 400 ft. farther. The Golden Gate property is southwest of Buena Vista, and the railroad has established a flag station there, to be known as Russell.——The Stewart mill is treating a shipment of six tons of ore from the Brownie mine at Buena Vista.——Robinson & Wells report a rich strike on their property about four miles from Beveridge.

NEVADA COUNTY.

(Special Correspondence).—A rich vein of ore has been struck in the 600-ft. drift on the 500-ft. level in the Idaho-Maryland mine. Several pieces of ore assaying nearly $100,000 per ton have been taken out. The main vein has widened to 5 ft. The shaft will be cleared out and retimbered to the 1000-ft. level. Bray Wilkins is general manager.——Development work is progressing steadily at the Spring Hill.——Rich gravel continues to come from the Jenny Lind. Cross-cutting is under way to determine the width of the channel. The mill will be started soon.——



A New Camp.

The Cook vein has been cut by the south drift in the Gold Mound mine. The shaft will be sunk deeper and a drift driven to develop ore. Howard Dennis is superintendent.——It is reported that the South Idaho mine will resume operations within a few weeks.——A rich strike has been made in the lower level of the Siberia mine in the Cherokee district.——Preliminary work has commenced on the big drainage and development tunnel, known as the Twin City subway. It is expected to open up much virgin mineral territory.——The Marysville Tunnel & Gold Quartz Co. is developing a promising lode on their gravel property near Mooney Flat.——A drift is being driven to develop the Golden Crown group.——The Ethel mine will resume activities soon. A. Maltman is superintendent.——At the Golden Gate the working force has been increased and development work is under way. Good ore is coming from the lower levels. W. P. Martin is superintendent.——Work at the Bessie mine in Brown's valley is progressing steadily. Several men are employed.——The force at the Union Hill mine has been increased. It is understood that work will soon start at the Cold Springs and Buckeye groups.

Grass Valley, May 13.

PLUMAS COUNTY.

A new corporation, called the Indian Falls Co., has purchased the Shoo Fly property, near Quincy, and will develop the mine, lay out a townsite, and build a tourist hotel.——Gobert & Treleaven report a rich find on their Old Harry claim, about 12 miles from Quincy on Squirrel creek.

SHASTA COUNTY.

(Special Correspondence).—The dredge at Horse Town on Clear creek is being lengthened and changed from the

double-lift to the single-bucket type.——A suction dredge of the Dubois type is working in the Sacramento river at the mouth of Clear creek, and one of the same type on the river opposite Redding.——The Bully Hill is treating ores from the Winthrop, the Anchor, and the Bully Hill mines, and by mixing all three it is said the smelter is running in excess of its rated capacity.——The Winthrop has uncovered 16 ft. of good ore at the point where the new workings struck the old.

Redding, May 13.

(Special Correspondence).—Development work at the Gladstone mine near French Gulch has opened up a new ore-shoot. The mine is producing $20,000 per month, and the prospects of a steady output are excellent.——At the Midas mine at French Gulch 100 men are at work. The mill and cyanide plant are running steadily.——A new 60,000-volt power-line is being built by the Northern California Power Co. from the power-houses at the foot of the Sierra Nevada, with branches to the Mammoth Copper Co.'s smelter at Kennett, being the fourth line supplying this town, and to the Noble Electric Steel Co.'s plant at Heroult.——At the Yankee John mine near Centerville, a narrow vein has been found unexpectedly in sinking the main shaft, at 165 ft. The ore shows coarse gold. Sinking will be continued to the 200-ft. level before driving is begun.

Redding, May 13.

The Great Western Co. is receiving bids for the construction of a railroad from Bella Vista to its smelter at Ingot. The line, the location surveys for which are nearly completed, is standard gauge and 14 miles long. The Great Western is developing its property on the 600-ft. level.—— The Mammoth Copper Co. at Kennett has permanently closed down its saw-mill because lumber can be purchased cheaper than it can be manufactured.

TRINITY COUNTY.

The Fairview mill will be put in shape, and the management expects to have 10 stamps dropping by June 15. A tramway will be built from the lower workings of the mine to the mill.

TUOLUMNE COUNTY.

The new two-stamp mill at the old Knox & Boyle mine, near Steut, was burned last week. Besides the building in which the mill was, a concentrator and a slime plant were destroyed.——The plant of the Sierra Lime & Cement Co., at Sonora, was destroyed by fire last week, although the kilns and boiler are probably not ruined.——Another big pocket of gold has been uncovered in the O'Hara mine, north of Sonora. It is reported that this find is even bigger and better than the one reported several weeks ago.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A bonanza strike has just been made on the Gambetta vein, intersected through the Joplin adit. In running the east drift, now in 200 ft., a streak of mineral 4 in. wide has been exposed that assays 100 oz. silver, 1 oz. gold, 60% lead, and 7% copper. For 150 ft. an 18-in. streak of 52-oz. silver and 60% lead ore has been followed. No effort is being made to break down the ore, as it has been decided to await the lifting of the bond before shipping. This is the first time in the history of mining on Republican Mtn. that gold in such liberal quantities has been found. The drift on the Gambetta vein is now directly under the old shaft workings, which were sunk to a depth of 70 ft. B. J. O'Connell serves as manager. ——During the month of April it is reported that 57 lb. of bullion was extracted from the amalgam plates at the Capital mill. The gold, which was sold at the U. S. mine at Denver, brought $16 per oz., making a total of $10,870. In addition to this, 40 tons of first-class concentrates was sold that netted $300 per ton, while the iron product, consisting of 160 tons, milled $27 per ton. The total production, not counting the smelting ore that was shipped, was $27,160. Another machine drill is to be brought into use in the breast of the Capital adit, now in 4800 ft. The next vein to be reached is known as the Sporting Times. W. M. Cooper is manager of the Capital M. & T. Co.——Shipments are being maintained from the Astor, where Butts & Co. is operating under lease on the 240-ft. level. Stoping is in progress on a 2-ft. streak of 350-oz. silver ore.——The Scepter adit is being advanced under contract, S. McKirahan having been the successful bidder. The bore is now in 2800 ft. and is to be driven 400 ft. farther, at which point a raise will be started to make connection with the Sunburst adit, after the completion of which all the ores mined on the west side of Democrat Mtn. will be brought out through the Scepter adit, the portal of which is on the Georgetown side. ——All the machinery for the Linn mill has now been installed, and the test run is scheduled for some time the coming week. The plant is modern in every respect and is equipped for straight concentration.——Work at the Hall adit has been resumed after 15 years of idleness. The old workings are being cleaned out and re-timbered. It will be necessary to equip the adit with new tracks, as a junk-dealer purchased rails, pipe, and compressor-plant a few months ago. B. J. O'Connell is manager of the new company.——The Socrates group of claims on Democrat Mtn. are undergoing development. The adit is now in 650 ft. and in the breast there is showing a 4-in. streak of silver-lead ore, which assays $65 per ton. The Tom Payne, which is a cross vein, will be reached within 20 ft. E. K. Cass is acting manager.——R. Fisher is driving the Hercules adit and is following a 10-in. vein of sulphide ore that carries silver as high as 300 oz. per ton. Occasional shipments are being made.——The Cully adit, on Saxon Mtn., is the scene of another important strike. In running the east drift on the Clyde vein an 18-in. streak of 175-oz. silver ore has been exposed. A heavy tonnage is being broken and shipments have been started. J. J. Cuily is manager.——The re-timbering of the Golden Glory adit is nearly completed. The company expects to install machine drills during the present month. According to surveys, the extension of the Bellevue-Hudson vein will be reached within 100 ft.——Heavy shipments are being maintained from the American Sisters mine on Columbian Mtn. Driving and stoping is under way on a streak of 400-oz. silver ore encountered on the 275-ft. level of the Headlight shaft workings. The 50-ton concentrating plant is running steadily, two grades of mineral being turned out. The first-class ore mills 300 oz. silver per ton and 25% lead, while the second-class is worth 97 oz. silver and 25% lead. Only the higher grade of ore is receiving treatment owing to low prices quoted on zinc. J. J. White is resident manager.——The Vesper group of claims, East Argentine, is undergoing development. The Bonham adit is being advanced to intersect the veins, and from surveys the Vesper lode should be reached within the next 25 ft. ——The North Star property is making an excellent showing, a streak of solid smelting ore having been uncovered that is from 3 to 4 in. wide. Tests upon the material show 19 oz. gold and 976 oz. silver per ton.——Shipments of smelting ore are now being made from the Wilcox adit workings. Lessees at work on the Commonwealth vein, 5600 ft. from daylight, are sending forth a heavy tonnage. Jameson & Sprousse are stoping on a body of mineral that is from 18 in. to 3 ft. wide, averaging $60 per ton in silver. Butler & Co., operating through the Tobin adit, are stoping on a 20-in. streak of $35 gold-silver-lead-copper ore.——The compressor plants at both the Wilcox and Tobin adits were started last week.——Shipments are being maintained from the Sporting Times mine, on Alpine and Griffith Mtn. The ore is a high grade and mills 1.54 oz. gold and 14 oz. silver per ton, with 62% lead. Stoping and driving is in progress, the orebody showing for over 50 feet.

Georgetown, May. 11.

GILPIN COUNTY.

The O. K. mine, on German Mtn., has been unwatered preparatory to sinking the shaft 100 ft. deeper. A winze is to be sunk from the sixth to the seventh level.——Jordan & McCallister are hoisting milling ore from their lease on the 200-ft. level of the Gold Collar mine.——Hawn & Emery, who are leasing in the San Juan mine through the La Crosse adit, in Nevada gulch, shipped a carload of smelting ore to the Argo plant last week.——Bennetts & Co. have taken a

lease on the Bull of the Woods mine, east of Galena, on Central City hill, and are putting the property in shape.——George Oldweiler & Co. are working the Justice mine, in lower Russell district, under a lease, and at present are doing some work in the 700-ft. level. The main shaft is down 800 ft., and the lessees expect to sink deeper.——Vosser & Co. have taken a lease on the Pewabic adit, in Russell district, and expect to do considerable development on the group.——Richards & Co., operating the War Dance property, in lower Russell district, have nearly completed the work of re-timbering the shaft to the 140-ft. level, and have their gasoline hoisting-plant in running shape.——Work will soon be started on the power-plant of the Seemann adit, on Fall river.——The mill at the Idaho Springs Reduction Works is being overhauled and will within 60 days be treating the ore from the Aduddell and the Half & Half properties.

SUMMIT COUNTY.

The Colorado-California Gold Mining Co. has been incorporated to resume operations on the Gold Dust claim.——Successful test runs have been made, both at the Wire Patch mill and the Colorado dredges.——The Blue Flag Mining Co., on Raven hill, treated during the month of March 600 tons of ore of an average value of $6, and shipped several thousand dollars' worth of bullion. A Tatman pulverizer is being added. The company's Laurium plant near Breckenridge is in constant operation and is turning out a high-grade concentrate. Another pulverizer is being added to this plant.——Thomas Gilroy, who has a lease on the Across the Ocean property on Breece hill, has started a new shaft 100 ft. west of the present shaft, and expects to tap the orebody which was struck in the old shaft.——Eight or ten men are employed on the Robert E. Lee property on Fryer hill, which is under lease to W. S. Jones and associates. The same men have also taken a lease on the Rupp Fraction, which adjoins the Lee, and are working both properties. Iron ore is being shipped from the Lee at the rate of about 30 tons per day, and considerable siliclous material is being taken from the Rupp.——Fred Cretney, who was leasing on the Forepaugh at the time the shaft-house was destroyed by fire last fall, has resumed operations on the property, and is now making regular shipments. Some repairs have been made on the surface plant, but the shaft-house has not been entirely re-built, as was at first proposed. The hoisting is being done through the Silver, which adjoins the Forepaugh. About 25 tons per day is being taken out and shipped to the Arkansas Valley smelter. The ore is principally silicious, but is said to contain from 40 to 50 oz. silver per ton.

TELLER COUNTY.

The mines in the Cripple Creek district during the month of April shipped a total of 1875 cars, with a total tonnage of 64,023 and a gross bullion value of $1,345,380. These shipments break all previous records so far as tonnage is concerned; however, the gross value is slightly less than that for March.——The fire which totally destroyed the shaft-house and machinery of the Lexington Gold Mining Co. on the west slope of Gold hill recently will not interfere with the plans of the company to a great extent. The head-frame, ore-house, and trestle were saved, and the present lessee, Iver Weston, will probably hoist his ore through the shaft of the E. Porter Gold King until an electric hoist can be installed.——The General Leasing Co., which has a lease on the Hardwood property of the United Gold Mines Co., has started operations. Modern machinery will be put in the 135-ft. shaft and cross-cutting started with the purpose of striking the famous Jerry Johnson vein.——The Anchoria-Leland Gold Mining Co. has started operations on the old ore-house dumps of the Anchoria Leland mine on the west slope of Gold hill. The dump, which is one of the best in the district, will be shipped with very little sorting, and good results are expected.——The Union Leasing Co. has resumed work on the Proper claim, which is on the northeast slope of Gold hill, near the C. O. D. and the El Paso Gold King.

IDAHO.

BOISE COUNTY.

A strike of free-gold quartz is reported on the property of F. H. Cooper, three miles north of Centerville.——The McKinley Mines Co. will start work on its adit within 30 days.——Work has been resumed at the adit of the Stockholders' Mining Co., southeast of Elkhorn.——An adit will be started to tap a vein on Chas. Clark's Elkmeat claim, west of Elkhorn.

IDAHO COUNTY.

J. O. Barbour, of Lewiston, has purchased the May Flower group on Deadwood Mtn., and has started an adit to cut the vein at the 150-ft. level.——Belor & Murphy have resumed development on their group of claims, near the South Fork mine.——The Good Enough mine, in the Marshall Lake district, has changed hands, the Irwin brothers, who have owned the property for several years, selling out to S. C. Edgar of St. Louis, Mo. A 10-stamp mill is to be installed this summer.——Elk Trail placer, at the mouth of Crooked river, will be started soon. Farr & Beekman, the owners, are installing a Ruble elevator.——The Gold Point, near Elk City, has started sinking the shaft to the 200-ft. level. A mill may be put in this year.

OWYHEE COUNTY.

A new transformer and motor were put in at the Potosi mine last week.——The crusher at the new Banner mill has been put in place. Everything will be ready for the mill to start as soon as the tramway is finished. A few more men have started work in the mine. All the work is being done in the No. 3 and 4 levels, and in the No. 1 level south of the raise.——The Atlanta mill, near Mountainhome, started crushing the ores from the Monarch mine last week. The mill has a capacity of 150 tons per day, and is equipped with both electric and water power.

SHOSHONE COUNTY.

(Special Correspondence).—The Last Chance mine at Wardner has resumed operations with between 200 and 250 men, and P. W. Peeples, superintendent, announces that 600 men will be employed at the mine and mill as soon as they can be assembled.——It is expected here that the Morning mine of the Federal Mining & Smelting Co. will be re-opened soon, but no definite statement can be obtained from the management. A few men are now employed there.——The Hecla mine at Burke has completed the installation of its new electric hoist, and this is now being tested, preparatory, it is said, to resumption of operations.——It is reported from the Champion mine that a new strike has been made there, equaling the recent strike of gray copper. This appears to be due to passing through a 'horse' which was 8 ft. in width. The new ore is said to be bornite and chalcopyrite of great richness.——Work will be resumed on the Idora, on Sunset Mtn., early in June, as the roads will then be passable. The property is developed by an adit in which galena of good quality has been found.——The Lucky Calumet mine will be operated with a full crew, beginning immediately, and work will be pushed. There has been a small crew at work for the greater part of the winter.——The Caledonia mine at Wardner has installed a new 5-hp. hoist, and this has been put in commission. Development work will be continued.

Wallace, May 11.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—The re-opening of the Bonanza tract and its development into active production has been one of the features of recent importance to the Galena camp. The land has been leased by a number of operators and a concerted effort made for unwatering the mines to a depth of 170 ft. The ground is mined from the surface to the 170-ft. level. The sub-lessees are working the shallow deposits while the half-dozen other companies are preparing to extensively develop the lower runs of ore. The Casco Mining Co. has been working for some time and has just completed the erection of a new concentrating plant.——On an adjoining lease of the same ground the Quincy

Mining Co. has taken a lease of six acres and has opened an 18-ft. face of high-grade zinc-blende at a depth of 44 ft. The second shaft is being sunk and driving has just been started. The excessive rainfall has retarded operations. ——Timothy & Co. have also taken a lease on the Bonanza ground and have the orebody well opened up for production. Better hoisting facilities have been installed and electrical power substituted for operating all the machinery.—— Harry C. Cooper and associates have just made a rich strike of zinc-blende in a shaft on this same ground. The ore cleaned upon hand-jigs is running 62% zinc.——An orebody of exceptional richness has been discovered between Fifth and Sixth streets, just behind the Century Hotel building. The deposit consists of galena in huge lumps and occurs at a depth of 120 ft. with a 7-ft. face. In opening up the drift the miners have been producing each shift 5000 lb. galena in pure chunks in addition to the milling ore. Beneath the run of galena a heavy deposit of zinc-blende was penetrated in the shaft.——At Cave Springs, northeast of Galena, the Herald Mining Co. has commenced milling the rich orebody recently opened. The ore occurs in a sticky chalky dolomite, being very hard to concentrate. The ore seems to break across both the blende and gangue rather than the gangue breaking free from the blende. This is the case even when the ore is crushed fine enough to pass a two-millimetre screen. The problem seems to be one of correct crushing, and other means than the ordinary Cornish rolls seems to be demanded. The ore mined runs as high as 25 to 30% zinc-blende and occurs in a sheet formation.——McCullagh & Murdock have undertaken the draining of the Hartley land, where over 30 shafts were productive in the early days. The land was mined to a depth of 110 ft. and some rich deposits worked, but were abandoned when the price of zinc ore dropped so low in the nineties. The land consists of 120 acres, which will be thrown open to lessees as soon as the draining of the tract has been effected.

Galena, May 11.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The recent decision of the Federal Court at Laredo, Tex., that all zinc ores are to be admitted to the United States free of duty, has caused the mine operators of this district to realize the necessity of pushing the case to the U. S. Supreme Court for a final decision. The operators have already spent $10,000 in securing a decision from the New York Board of Appraisers favorable to the levying of a 20% ad valorem duty. This decision has been contested by the smelters and is pending in the courts. The last decision, by Judge Wallace Burns of the Federal District Court at Laredo, Tex., was the result of a case filed by Calvin G. Brewster, an American zinc mine operator in Mexico, to contest the decision of the Secretary of the Treasury. The decision makes it possible to import, duty free, not only blende, but the silicate and carbonate of zinc as well. Zinc ores having a lead content must pay a duty upon the lead content only. The smelter interests are using all the pressure they can, to get the Secretary of the Treasury to accept the decision of the District Court, but the mine operators of the Missouri-Kansas district and of Wisconsin are determined to carry the case to the Supreme Court. To that end the operators of the Missouri-Kansas district are forming an organization for the purpose of furnishing the necessary funds to continue the contest. The organization of the operators in this field has never been a success, but the present agitation has been along new lines. The raising of funds will be proportioned among the members according to the production, a pro ratum being assessed against the tonnage each week. According to this plan the fund available each week would range from $250 to $600—a sum amply sufficient to carry on the work outlined. Hitherto the funds have been provided from the contributions of individual operators.——The strike of the workmen at the Cherryvale smelters of the Edgar Zinc Co., which occurred last week, has been settled satisfactorily to the management and to the workmen, and according to the terms of the agreement the men returned to work this week. The Edgar Zinc Co. has five furnaces at this place and employs 350 men.—— The Bull Frog Mining Co., operating a 30-acre lease west of Joplin, at Smelter Hill, has enlarged the scope of its present workings by sinking a new shaft southwest of the mill. The new shaft is principally a lead producer, and has been connected with the concentrating plant by means of an inclined tramway. Southeast of the mill an especially heavy body of rich milling ore has been discovered and is now being opened by a drift driven from the old workings. The drilling has revealed enough reserve orebodies to run the present 300-ton mill for a number of years.——A new development of mining ground was made on the Lucky Jim Mining Co.'s land west of the city. The company has been developing a 12-acre lease by drilling and shaft-sinking. Two shafts are now in the orebody and the driving has revealed a large body of high-grade milling ore, chiefly zinc-blende. The company is erecting a 350-ton plant, which will be completed within a fortnight. The plant is modern in both building and equipment. This will make the third large producer in that immediate vicinity within the past nine months.——Still farther west, on the land of the Old Times Lead & Zinc Co., the Great Western Mining Co. has secured a new lease and is putting down a shaft to a sheet orebody at a depth of 200 ft. The company has sunk this shaft to 173 ft. already and will begin the sinking of a second shaft at once. In addition, a 350-ton concentrating plant will be erected during the opening of the drifts. This same company has purchased the mine and mill of the Old Times company at Central City and will re-open them as soon as the ground can be drained.——On an adjoining lease of the Black Cat land the Commonwealth Mining Co. has undertaken the development of two 10-acre tracts. One of these has been drilled and found to be underlaid with sheet-ore, and the sinking of shafts is now in progress. Upon the other the company is operating two steam-drills and will thoroughly drill the lease before sinking any shafts.——Another new plant is that of the Under Roof Mining Co., in course of erection on the land of the Granby Mining & Smelting Co. at Chitwood. The plant handles 200 tons in a 10-hour shift. The company is working two bodies of ore, one at 100 and another at 170 ft. The ore is zinc-blende in both levels. The company has just completed drilling the lease, and in three of the drill-holes ore was discovered at 170 ft. One new shaft will be sunk and the present shaft will be lowered to the 170-ft. level.——A company composed of O. H. and W. H. Picher, Geo. Coburne, J. H. Tonklin, Albert Arnold, and Phillip Janney have purchased the Street mine on the Continental lease west of the city. The mine has developed into a good producer by the discovery of three rich runs of ore. During the development the company will erect a concentrating plant to take the place of the hand-jig plant now in use. The new orebodies contain both galena and zinc-blende.——A heavy deposit of low-grade ore has been opened in the Emperor mine in Gordon Hollow. The deposit extends from a depth of 90 to 140 ft. The upper portion of this deposit consists of a mixture of pyrite and zinc-blende, which when concentrated assays at best only 58% zinc. The deposit, however, is free from gangue, and the mill is taxed to care for the concentrate coming from the jigs. Below the upper portion a second layer of high-grade zinc-blende occurs which is free from pyrite and assays 60% zinc. The mill is a new producer and is turning in a large tonnage of concentrates from a hitherto abandoned camp.——A very rich deposit of galena has been opened in the Water Witch mine in the Kansas City bottom, east of Joplin. The mine was recently re-opened by Chas. Edwards & Co., who discovered the deposit in the eastern edge of the lease.——A new development in the Spring City district, south of Joplin, has been made by the Delta Mining Co. In a shaft at a depth of 180 ft. driving has encountered heavy bodies of blende and calamine, with a little galena intermixed. A heavy volume of water has hindered the opening of the deposit, but since the installation of a heavier pumping plant the work has progressed rapidly. A concentrating plant is now

being erected and will be designed to separate the three minerals and also eliminate the gangue. The plant will handle 200 tons per 10-hr. day.——In the Webb City camp, north of Alba and north of the north fork of Spring river, the Quick Seven Mining Co. has made a new strike of ore in absolutely virgin territory. The strike was made at a depth of only 20 ft. and continued to 60 ft. At a depth of 180 ft. another deposit 20 ft. thick was penetrated. Two holes have shown the same record, but a number of other holes will be drilled before sinking any shafts.——South of Duenweg, on the Schifferdecker land, Congdon, Smith & Co. have undertaken the re-opening of a rich tract recently lost on account of the shafts being flooded with high waters. A heavy pumping plant is being installed. The company was formerly taking out a good quality of free ore and concentrating it upon hand jigs. The ore occurs at 60, 80, and 120-ft. levels. The ore is galena and zinc-blende.—— The Aledo Mining Co. at Duenweg, entered the list of producers from that camp the past week. This company has developed a mine on the Hall land and has opened a good body of milling ore at 180 ft. A concentrating plant has been erected and the first ore was 40 tons of concentrate running 60% zinc.

Joplin, May 11.

NEVADA.

CHURCHILL COUNTY.

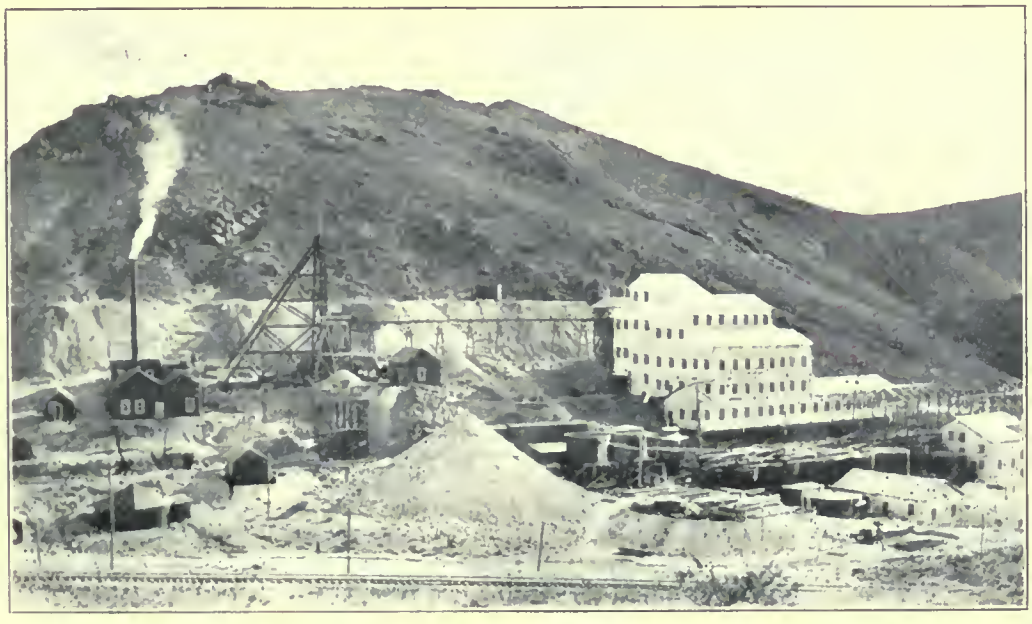
The I. X. L. mine, in the western part of Wonder district, is again shipping ore. A 4-ton lot sent to the Hazen sampling works yielded returns, as reported, of nearly $5000. ——The miners in the Fairview district have accepted the Tonopah scale of wages. This will probably mean that a number of the properties in that district which have been inactive for some time will be opened.

ESMERALDA COUNTY.

A strike of importance to Goldfield is reported at the Mohawk. In cross-cutting toward the Jumbo territory on the 600-ft. level a body of ore was cut which is 19 ft. thick and assays $65 per ton. This strike is of significance in showing that the rich ores in the Goldfield district are not only at the surface.——The Florence Extension has cut a good body of ore 5 ft. thick, which is probably the Little Florence lode.——The Thomas lease on the Combination No. 3 is being put in shape for active development. The shaft is being enlarged and a head-frame erected. A 30-hp. electric hoist will be installed and the shaft sunk to the 500-ft. level. Oswald Stein is manager.——The concrete work for the new Combination mill is almost completed, and the erection of superstructure and machinery will start soon.—— The 40-hp. hoist for the Grutt Syndicate arrived at Rawhide last week and will be operated as soon as the head-frame is completed.——The total shipments from Goldfield for the week ending May 9 were 1715 tons, valued at $99,265.

HUMBOLDT COUNTY.

A 10-stamp mill is being installed at the Mountain City mine, in which Goldfield parties have recently become interested. The Little Gladys group is also being steadily developed. A promising vein has been struck in this property. ——The miners' union of the Seven Troughs district has agreed to a wage scale which involves a reduction of from 50 to 75 c. per day from the scale which has been in effect, and precludes the possibility of labor trouble for some time to come. The agreement provides for the following graduated scale of wages: Muckers and top-men, miners, driving and cross-cutting, $4.25; miners, sinking and raising, $4.50; miners, wet-shaft work, $5 (men to furnish their own rubber clothes and boots); engineers and timbermen, $5.——The Imlay Con. Co., four miles southeast of Humboldt House, has made a strike in a 40-ft. drift from the 140-ft. level. Some high-grade ore has been found on the hanging wall that assays $1 per lb. The ore runs 12 to 15 oz. gold and several hundred ounces in silver. The adjoining vein is 8 ft. wide.



Montgomery-Shoshone Mill, at Rhyolite.

NYE COUNTY.

The machinery for the Tonopah Buckeye Mining Co., at Tonopah, has arrived and will be taken to the property and installed as soon as possible. The outfit consists of a 44-hp. hoist and the most up-to-date operating necessities. The head-frame at the mine has been placed in shape to receive the cage. With the installment of the machinery, operations will be pushed with greater activity than ever before. ——Rich samples have been found at the Pritchard property on Melklejohn Mtn. near Bullfrog. Eight sets of lessees are developing the claim.——The Homestake has purchased the six-drill compressor plant at the Red Oak property, which will be moved at once and mining operations resumed. All material is on hand for the 25-stamp mill, now under construction, and its completion will be rushed.——Ground has been broken for the custom mill which C. R. Campbell will build in the Bullfrog district.——The Bullfrog Pioneer has received its 15-hp. hoist and it is now being installed. The leasing company will operate the plant as soon as the Huntington mill, which is now on the way, arrives and is set up.——Peter Vuich and Thomas Suraka have taken a one-year lease on a portion of the West Extension property. ——At the Burns-Anglin-Peterson lease on the Capricorn the shaft is being sunk to the 100-ft. level.

Special Correspondence.

LONDON.

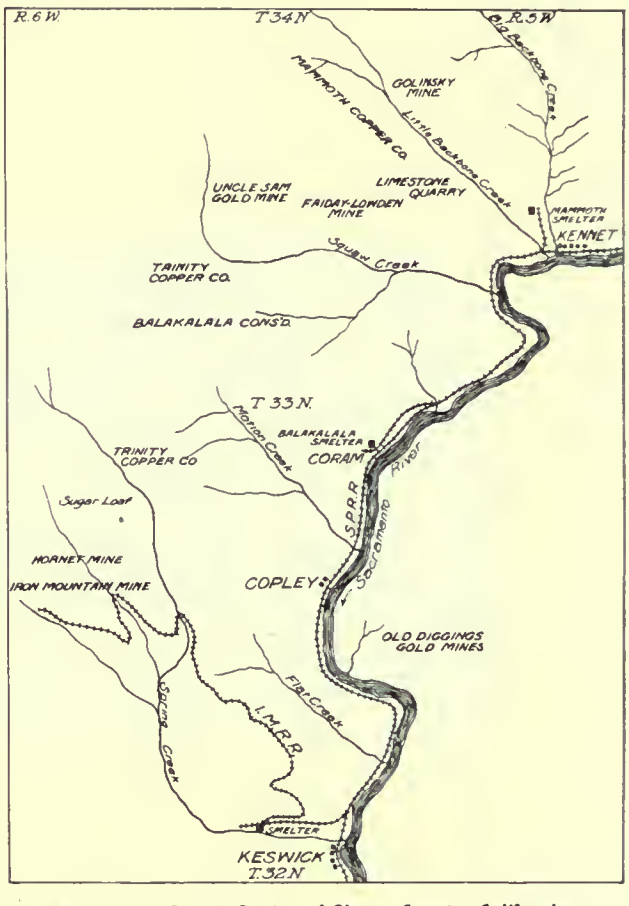
Mountain Copper Co.—Conservative Financiering.—Tharsis Copper Co.—Esperanza Litigation.

When dealing a few weeks ago with the forced reticence of the Rio Tinto Co. with regard to its policy and operations, I mentioned that the Mountain Copper Co. of California, which is under the same control, is equally chary of giving information as to its doings, on account of the annoyance caused by the political blackmailers. It is not surprising therefore to find that the official report for 1907 of the Mountain Copper Co. is exceedingly bare of details. All it says is that 3407 tons of copper were marketed during the year, against 2854 in 1906; that the output of sulphuric acid and fertilizers has been successfully marketed, and that the profit for the year was £150,254. This is all that is said relating to the figures and results, but the directors add a few words as to their policy. During the earlier part of 1907 the prices obtainable for copper were very good. Taking advantage of the higher prices, the company treated as much ore as possible, a fact which accounts for the higher output. I have always said that the Rio Tinto people can guess the future of the copper market better than anybody else. This is certainly a case in point. For the past nine months the output has been restricted until the price goes up again, but, let me add in parenthesis, not restricted to such an extent as to increase the cost of production. The directors have looked closely into costs and they state that it has not been possible to get the cost of labor, supplies, and material to as low a level as was customary in 1904, before the recent great boom in prices and trade occurred. However, with the decrease in employment, labor is becoming more efficient, which will to some extent make amends.

The directors distribute the usual interest on the debentures, but are not redeeming any at present, preferring to keep money in hand. Your readers will remember that the share capital of this company is practically non-existent, amounting to the nominal sum of £20. In 1899, when it was found that the mine was of limited extent, the company was reconstructed and the bulk of the capital converted into redeemable debentures. In other words, £1,250,000 in shares was converted into £250,000 in shares and £1,000,000 in debentures. Only £20 of these shares are issued, the remainder being held for issue at some future time when the debentures are redeemed and new property acquired. So far £250,000 of the debentures have been redeemed. More would have been redeemed if it had not been for the necessity of removing the smelting works from Keswick, and the desirability of extending operations whereby the barren pyrite could be utilized. I desire to call the attention of your readers to this policy of the Mountain Copper Co. of providing for the reduction of capital concurrently with the exhaustion of the mine. Last week I gave some cases of writing down equipment. To be logical, allowances should be made in the balance sheet for the depreciation of the mine as well.

While speaking of this method adopted by the Mountain Copper Co. of writing off the value of the mine as well as of the machinery, it occurs to me that it is opportune to give information about the same policy adopted at two of the copper mines in the south of Spain and Portugal, the San Domingos in Portugal, belonging to Mason & Barry, Ltd., and the Tharsis & Calanas in Spain, belonging to the Tharsis Sulphur & Copper Co. The Mason & Barry Co. was originally formed in 1878, and for a number of years paid good dividends. In 1892, as the limits of the property were ascertained, arrangements were made for writing down the capital from time to time. There were 185,172 issued shares of £5 each, and in 1894, '96, '98, and 1900 a sum of money equal to £1 a share has been returned to the shareholders, and the nominal value of the share reduced accordingly. The issued capital of the company now stands at £185,172 in shares of £1 each. The funds in hand at the present time consist of investments and cash in bank amounting to £173,000. I am not able to say how long the mine will last, but I believe it has several years' life before it still. During 1907, a mining profit of £67,216 was made and dividends absorbing £55,551 were paid, being at the rate of 30 per cent.

The Tharsis Co. was floated in 1866, and its capital has been £1,250,000 since the beginning. The average dividend has been 20%, varying slightly with the fluctuations in the price of copper. These properties have been known to be limited for some time, and yearly sums have been placed aside to accumulate against the depreciation of the mines. In the balance sheet, the property assets consist of mines, railways, works, and so forth, valued at £174,188. The total original cost has been £2,590,254, of which about half was for property and half for plant. The total amount written off to date has been £2,416,065. Of the present value, £174,188, the mines account for only £20,000, the railways in Spain for £64,940, and the plant in Spain and England for £99,248. The other items in the balance sheet consist of £324,065, the value of stocks of ores and metals in the course of treatment, and £1,138,244 in cash and securities. The actual sums distributed as dividends during the 41 years' life of the company total £8,852,182. For the year 1907 the net profit was £292,896, and £250,000 was distributed as dividend. The production of copper during 1907 was 4410, as compared with 4739 tons in the year before, the decrease being due to the gradual reduction in the copper-content. Of this, part was produced on the spot by washing, and the remainder was extracted at the English and Scotch works of the company. The amount of copper precipitate shipped from the mines for refining was 2753 tons, and the pyrite shipped, including washed ore, was 406,015 tons. The recent fall in the price of copper has had little effect so far, as with Scotch shrewdness the directors sell ahead in boom times. What is to be done with the accumulated funds is not yet decided. It has always been the intention to acquire other properties. Recently some prospects in Arizona were taken up, but did not justify further expenditure. The difficulty is that sellers of property always want more than the Tharsis people will give.



Map of the Copper Region of Shasta County, California.

On a big property, the sellers generally offer the Tharsis Co. nothing but smelters' profits and want all the mining profits for themselves. This is of course not enough. The shareholders are quite content with the interest on the accumulated funds, which yield £41,679 a year, until the time comes when a reasonable proposition is put before them by the owners of properties.

A few weeks ago I referred to the case of the San Vicente copper mine in Spain, where the English shareholders were endeavoring to get rid of their liability, owing to the mine not being equal to their expectations. There has been another dispute in connection with an adjoining copper mine also floated recently, namely, the Esperanza. In this case the dispute was the other way round, the vendors, who were debenture holders, alleging that the directors of the English company which had bought the property were not managing the business in a proper way. An application for receivership made on behalf of the debenture holders was not successful, but another action of somewhat similar character has been entered on the lists in the high court. Owing to the case being *sub judice*, I am not able to deal with the subject in the way I should like, and must content myself with bare facts. The difficulties of the company have been several. In the first place the working capital is insufficient, secondly, delays occurred in shipping the ore, and thirdly, the accounts have not been made up as early as they should. The company was formed in February, 1906, and the report was made by Robert Addie, who is well known in the western States of America. The mine was sufficiently far developed for almost immediate shipments. Somehow or other it was not possible to dispose of the shipping ore at first, a fact which showed that arrangements for the sale of the ore had not been made beforehand in the orthodox way through the ore and metal merchants. This has been remedied and the output to the end of 1911 has been contracted for. From February, 1906, to the end of December, 1907, the total shipments of cupriferous pyrite was 57,738 tons, whereas during the first three months of the present year, the shipments had risen to 22,000 tons. Want of capital has militated against progress in many ways, more particularly in the adoption of a leaching process. The company could not afford to lock up the capital involved in this process. The other grievance, relating to the absence of published accounts, has now been removed by the issue of a balance sheet and a profit and loss account to the end of December. Seeing that the profit in Spain, after allowing for depreciation and proportion of mine development, amounted to £24,284, the position of affairs is not quite so bad as might be supposed on hearing that a receiver had been asked for. No doubt the directors in future will be able to assume a more business-like attitude.

BENGUET, P. I.

Mining Association Formed.—Mining Code Drafted.—Bua, Clark, and Camote Properties.—Railroad Development.

Mining in the Philippine Islands has always been hampered and retarded by either a total lack of a proper mining code or a poor set of mining laws. A recent meeting of the Benguet Mining Association proposed to correct this evil by drafting a mining code embodying all the best laws of the United States and Canada. Members of the Philippine Commission had already given assurance that such a set of laws would be passed by them if not in conflict with United States laws. Confirmation by the Philippine Assembly is then all that is necessary to give the Islands as good a set of mining laws as any country in the world. There is no question but that the Assembly will pass upon these laws immediately. Lode claims are limited to 300 meters square (22.23 acres), with no extra-lateral rights.

The Benquet Mining Association has only been in existence three months, but its many good results are already beginning to show. It has made five permanent collections of Benguet ore, one of which was at the Manila carnival. Through its efforts the Mining Bureau has decided to put a corps of engineers at work immediately making a topographical map of the Baguio district. It is intended to get like associations formed in other provinces, with the ultimate object of forming a Philippine Mining Congress with permanent headquarters in Manila.

The Antimok portion of the Baguio district is the most active mining region in the Islands today. Perhaps the strongest company operating there is the Bua, with 40 claims patented. They have just finished a test of their new mill, which will be put in continuous operation in about two weeks, when the tramway from the main mine workings shall have been completed. This mill, driven by a Pelton water-wheel, consists of six quadruple-discharge Hendy stamps, amalgam plates, and complete cyanide plant. The Benguet Consolidated, or Clark's property, consisting of eight claims, adjoins the Bua on the west, and has been turning out a steady stream of bullion with its three Hendy stamps and cyanide plant for the past two years. Three additional stamps are now in place alongside and will start dropping as soon as the slime plant is completed. The slime will be cyanided separately by agitation in tanks fitted with stirrer arms. Finer crushing will then be resorted to, so as to effect an additional saving.

The Camote company, owning a single claim east of the Bua property, is operating a three-stamp mill of the ordinary type with 750-lb. stamps. This mill has neither a rock-breaker nor a cyanide plant, and is only saving about 50%, or about $7 per ton, and crushing two tons per stamp per day. The tailing, however, is being stored, and a modern mill will be installed as soon as development work now progressing shows the true character of the ore, as in depth it is sure to be different from the oxidized surface-ore now being milled. Three main tunnels at 50-ft. intervals are being driven ahead on the vein with all possible speed. These three properties are east of Baguio six miles, while to the southeast about the same distance is the Murphy property, also a producer. The mill here consists of screens and an amalgam plant which treats less than two tons per day. The Major Mining Co., operating between the Murphy property and Antimok, is about to install a small experimental mill. This property was only located last November. More development work is now going on in the Province than ever before, and new strikes are being reported daily.

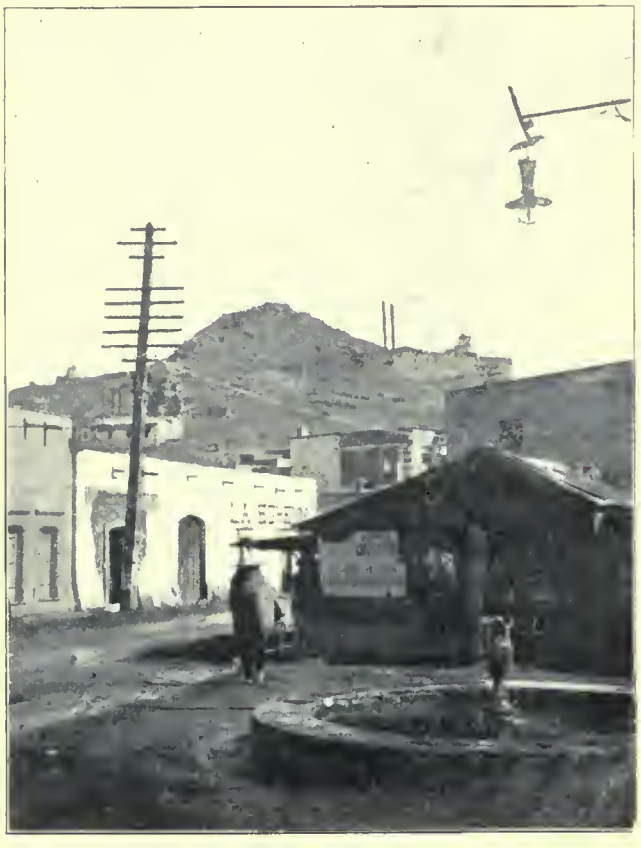
Transportation has been a serious problem and has retarded mining and all other industries here. The bridges on the Benguet road cannot carry a piece of machinery weighing over 3000 lb. Trains have just started running into Camp 1, which is within twenty miles of Baguio, the capital and main distributing point for the Province. This shortens the bull-cart haul 30 miles and places Baguio within a day's journey of Manila. An electric road is now assured from Camp 1 to Baguio, the grades being too heavy for steam. The steep mountains here will furnish plenty of water-power for electric generation. There is some promise of a smelter in the near future, as a representative of the United States Smelting, Refining & Mining Co. has been here for the past five months examining copper and gold properties.

MEXICO.

Discoveries at Parral.—San Francisco del Oro.—Activity at Santa Eulalia.—A. S. & R. Co. Smelter at Chihuahua.—La Republica.

It is with genuine pleasure that we note in the State of Chihuahua a revival of interest in mining and an awakening from the lethargic conditions so widespread last fall. The most promising strike for years past is that made in the latter part of April by Antonio Morales, a poor ranchman, in the Parral district, only a short distance from Parral. The first trial shipments of two lots, making a carload altogether, to the American Smelting & Refining Co.'s agency at Parral give returns respectively of 150 oz. and 800 oz. silver, and $^{1}/_{10}$ oz. and $^{1}/_{4}$ oz. gold per ton, and Morales is already spoken of as a second Pedro Alvarado. A great rush for denouncements was immediately made, and already the holdings of Morales are completely surrounded by new locations, among the largest number having been made by Bert Peterson, one of the most successful

operators in the Parral district. On the west side of Parral the San Francisco del Oro Mining Co. has completed its 50-ton experimental mill, under charge of the Minerals Separation Co. of London, which holds the foreign patents for the Sutton-Steele dry-concentrating tables and the Sutton-Steele static separator; and in addition to this the company is preparing to resume shipments of its clean high-grade ores. At the Cigarrero property, east of Parral, in the Almoloya district, another rich strike of copper ore running over 100 oz. silver has just been reported, but the rich owner of this property is making small shipments, waiting for a rise in the price of metals. At the same time he is opening up his already large orebodies. Almost adjoining the Cigarrero lies the Guadalupe, which has just been taken over by W. D. Pearce, resident manager for the Mexican Mines Corporation of New York, under a bond given about one year ago. During that time the company has opened up good bodies of ore running as high as 36%



Santa Cruz Hill, Parral, Mexico.

copper. The Mexican Rica Mole Mining Co., with a capital of $2,000,000, subscribed in Denver, and the El Porvenir Mining Co., with $3,500,000 of Paris and Denver capital, both with about 25 pertenencias (about 60 acres) near Parral, under the charge of Nat. P. Wilson, are working in good ore and are making preparations for ore shipment. In the Santa Eulalia district, near the city of Chihuahua, C. O'Callahan has started shipment from the new orebodies in the Santander and the San Antonio Chico, comprising some 100 pertenencias, in which the ore is now being developed, were dropped out by the Santa Eulalia Exploration Co. (Buena Tierra) from the ground purchased by that company from Mr. O'Callahan about two years ago. In addition to this, it is stated that L. M. Terry has run into a good body of ore in the Inglaterra, that R. J. de Morambert has found the ore in the Florencia, and that on the El Cristo a remarkably high-grade lead and silver ore has been found. The report is current that Chas. M. Schwab has made a payment in the New York offices of the Chihuahua Mining Co. for an extension of his option on the properties of the Chihuahua and Potosi mining companies. Orders have been sent from the headquarters of the American Smelting & Refining Co. to prepare the Chihuahua smelter so that operations may be begun soon after June 1, and ore is now being diverted to that plant. It is an entirely new plant, and has never been in blast, though practically completed (at least three of the six furnaces) last November, with the intention of blowing in during January of this year, but the falling off in the ore production throughout Mexico because of the prevailing low prices for metals caused the cessation of this construction work about February 1. Now it is understood there will be a sudden renewal of activity, but what has occasioned it, whether it be the requirements of the company's concession from the State, or the knowledge of some new source of ore supply, or some deeper motive, cannot be determined; certain, however, it is that the blowing in of the Chihuahua plant of the American Smelting & Refining Co. will bring relief to many, arouse new hope in others, and to all throughout the State of Chihuahua, whether directly or indirectly interested, it will appear as a sign that improved conditions are at hand.

The latest news from the Republica mine is very encouraging. The cyanide mill is now in regular operation. The tube-mill crushes all the ore to finer than 150-mesh and the first experimental run of the cyanide tanks gave an extraction of 80%. If any difficulty is experienced in the freighting of silver concentrates from the mine to the railroad these will also be cyanided, with the exception of the first streak on the tables, which runs over 2000 oz. silver per ton. This rich concentrate will not exceed 10 tons per month. The ore on the 300-ft. level is still looking extremely well. The level is now 111 ft. long; the average width of the vein is approximately 12 ft., with the ore assaying 175 oz. silver per ton as a general average throughout. The surface holdings at the mine have been increased from 166 to 366 acres, and now cover more than 8000 ft. on the outcrop of the vein. The company will ultimately increase the number of stamps in the mill from 10 to 15, and later on to 40. The tube-mill has been built to slime from 1200 to 1500 tons of ore per month, while the present stamping capacity is only 700 tons per month. There remains blocked out in the mine over 41,000 tons of ore immediately available. In addition, the faces of the exploration levels are still in high-grade ore. In sinking the main shaft to the 400-ft. level a small stream of water was cut when the vein was reached. A regular station pump will be installed at the 300-ft. level.

ROSSLAND, BRITISH COLUMBIA.

Blue Bird.—Centre Star Shipments.—Diamond-Drilling at Phoenix.—Devlin Group.

Mining in Rossland still continues to look promising. The large mines are pushing development and shipping a regular quantity of ore every week. Among the South Belt prospects the Blue Bird is still showing up well. L. Carter of Spokane states that the Blue Bird company, of which he is president, will operate the property after the expiration of the present lease, on December 6. The lessees of the Mayflower are taking out ore, and a copper orebody has been found on the Nest Egg. Several other claims have been leased and staked. The Red Eagle joined the shipping list last week, sending a car of picked ore to Trail smelter. The following ore shipments were made from the camp for the week ending April 25: Centre Star, 3450 tons; Le Roi, 1295; Josie (Le Roi No. 2), 210; Red Eagle, 20; giving a total of 5065 tons. The Centre Star is now the heaviest shipper in the camp. The Trail smelter has contracted for 100 tons of 4% copper ore from the Snowstorm mine in Idaho.

The Granby mines shipped 19,905 tons of ore during the week named above, and treated 19,721 tons at the smelter. This makes a total of 334,810 tons mined and 326,224 tons treated this year to April 25. Phoenix shipments for April will not equal those of March, but the general average is much higher than for either 1906 or 1907. At times only seven furnaces were operated this month, one having shut down most of the time for repairs. Diamond drill has been resumed. The side-dumping five-ton cars on the 400-ft. level are working satisfactorily and will reduce

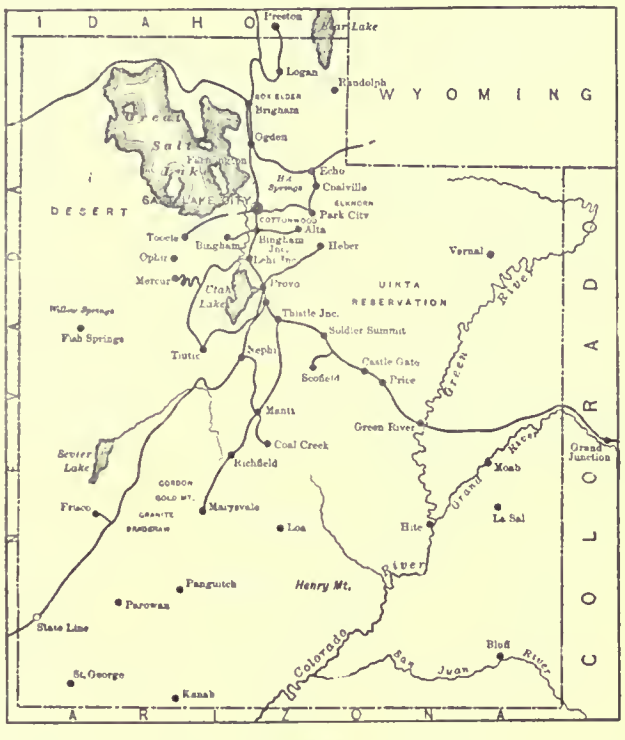
the cost of handling ore on this level. The cars are operated by electric locomotives. Diamond-drill development is in progress on the lower level of the Ymir. The management feels sure that the orebody will be encountered in depth. All that is required is sufficient money to execute needed development. In mining circles here the story is going the rounds that the owner of the Westmount in Slocan developed that property. It is over ten years since he began a 1000-ft. tunnel to tap the lode. Alone in the hills he worked on his claim for months at a time without hearing the voice of a fellow being. Success has now crowned his tenacity of purpose. The last car of ore shipped from the Westmount averaged 405 oz. silver per ton. On the Devlin group, Sheep creek, the lode is showing up 6 ft. wide, carrying $15 in gold per ton. There is a 12-in. paystreak on the hanging wall carrying $100 per ton. The Silver Cup is to be developed by a tunnel 400 ft. lower down than any existing adit.

SALT LAKE, UTAH.

Yampa Mine.—Methods of Mining a Wide Vein.—Consolidation of Tintic Mines.—Increased Ore Shipments.—Ontario Drainage Adit Restored.—Conditions at Park City Improving.

The Yampa mine of the Tintic Mining & Development Co., situated in Bingham canyon, requires thorough timbering. The company buys its timbers for square sets already framed, and it is stated that the cost in this form does not exceed that of timbers in the rough when the cost of framing on the ground is added. At the upper tramway terminal new 600-ton bins have been erected. The aerial tramway, two miles long, delivers the ore to the company's smelter. Between 400 and 500 tons of ore per day are now being moved. The converters now being installed will be ready for work within about six weeks. A new Ingersoll-Rand air-compressor has been installed at the mine. The compressor is driven by and is direct-connected to an alternating induction-motor, rated at 300 hp., operating at 145 rev. per. min., and has sufficient capacity to operate 35 air-drills. The drill-sharpener, of the Numa type, in the blacksmith shop, will sharpen 300 drills per day. The compressor-room, tramway terminal, blacksmith shop, and offices are near the portal of the main haulage adit, which penetrates 3000 ft., to a point where it intersects the Yampa vein. The ore is hauled out in trains of six 3-ton cars by electric locomotives. One locomotive is a 5-ton Jeffrey and the other a 3½-ton General Electric. Where the main adit encounters the vein a branch track leads 200 or 300 ft. straight ahead into the quartzite foot-wall to the 600-ton loading bins, which receive the ore from the eight working levels above. Another branch from the point named is a drift on the vein, extending between 500 and 600 ft. along the strike. The vein, which occurs along the contact of quartzite and limestone, has a dip of about 26° to the north. The ore consists of a clean heavy iron-copper sulphide, penetrating both the lime and quartzite. Above the haulage adit are 12 levels, 8 of which are now active. At a point in the main adit 3500 ft. from the portal is the base of a new incline which extends up to the 400-ft. level, keeping between the walls of the vein. This incline is double-tracked, a 5-ton skip operating on each track and dumping ore into chutes on the 1100-ft. level. These lead into the main ore-bins on the 1200-ft. level, which is the main adit. The work of driving and stoping goes ahead on both sides of this incline, the ore being dumped from cars on each level into skip-pockets, the latter discharging into the skips that move on the incline-tracks. These skips are operated by an electric hoist situated at the head of the incline on the 400-ft. level. The great width of the vein and the regularity of the dip are remarkable. The method of mining is to break down the ore and put in square sets, advancing a breast of three sets wide from wall to wall. As illustrating the width of the vein it is observed that in some places it requires 27 sets horizontally to fill the space between walls. On some of the levels the ore mined on the strike of the vein shows a length of 80 square sets. There is but little waste rock between the walls and the practice is to mine and send all the vein-matter to the smelter. The deposits on the lower levels, that is, from the No. 8 to the No. 12, are wider and of better grade than were those on the higher levels. On the operating force of the Yampa are the following: J. C. Dick, general superintendent; N. Treloar, mine superintendent; E. E. Price, mine foreman; G. W. Metcalfe, smelter superintendent.

A consolidation of the Swansea and South Swansea mines, in Tintic, has been arranged and special shareholders' meetings have been called to ratify the deal, and to organize a new company, to be known as the Swansea Consolidated. It will be capitalized for 1,000,000 shares, 300,000 of which will be issued to shareholders of the Swansea and South Swansea companies, the balance going into the treasury to be disposed of as the board of directors may deem best. The Bullock Mining & Milling Co., operating in Tintic, has purchased six additional mining claims to be paid for in stock, which is to be obtained by increasing the capital from 300,000 to 600,000 shares. The vendors will get 125,000 shares, the remaining 175,000 shares going



Utah.

into the treasury. The Bullock is one of the new producers of Tintic. Ore shipments from Tintic last week amounted to 67 carloads, the contributing mines and amounts being: Bullion Beck, 3; Centennial Eureka, 46; Eureka Hill, 10; May Day, 4; Yankee Con., 4. The ores from the latter are shipped to Salida, Colo., and the Centennial Eureka product goes to Kennett, Cal. The Carisa Mining Co., of Tintic, has arranged to ship its ore to the Yampa smelter in Bingham canyon for treatment. The Grand Central mine at Tintic has resumed operation after a shut-down of about five months. Ore shipments will begin to the Tintic smelter about May 15, on which date the ore purchasing department of the new smelter will be ready for business.

The Ontario drain adit at Park City has been restored. At least the water in the workings of the Ontario mine has been lowered to the adit level, and the management will probably know in a few days how seriously the three years of inundation has damaged the levels from which ore was being extracted prior to the disaster resulting in the caving-in of the avenue in March, 1905. Almost from the very day it happened the work of restoring it has been under way. The task has been a dangerous one, but the records show that only one fatality has occurred, and that was due to no fault of the employers. When the accident happened it was thought the trouble would soon be over-

come, that the timbers had given way only at one weak spot which was then being repaired. Subsequent development proved that a series of caves had occurred, and that it might take months or years to remove them. Such has been the case, and whenever an obstruction was encountered parallel drifts were run around them, the extent of the caves being determined by means of drill-holes run in to the main avenue from time to time. The Ontario drain adit was located in 1888. Work was begun on July 25 of the same year, and completed to an intersection with the 1500-ft. level of Ontario No. 2 shaft, a distance of 15,494 ft., on October 7, 1894. The cost of this section of the adit was $671,011, the expense being borne jointly by the Ontario and Daly mining companies. The present length of the adit is about 25,000 ft., having been extended from Ontario No. 2 shaft to the boundary of and across the Daly company's property into the Daly West ground. The importance of the Ontario adit is emphasized by the fact that since it has been obstructed, it has been impossible to operate the lower levels of nearly all the producing mines in the Park City district, the mines most seriously affected being the Ontario, Daly, Daly West, Silver King, and American Flag. Consequently, plans that had been outlined to explore them at greater depth were frustrated for the time being. The Daly West and Silver King then confined their operations to the ore deposits near the surface, as did the American Flag; but the Ontario and Daly mines closed down tight. During the past year the Silver King and Daly West have not kept up steady production, and their annual reports show that the output has gradually decreased from the date of the disaster. Likewise, dividends have been either reduced or suspended. None of the Park City mines are paying dividends now, but the re-opening of the adit will bring about a return of old time conditions. The camp has already begun to feel the effect of the restoration of the adit. The outlook for the camp is bright, and on the local mining exchange the daily quotations and sales show that interest is being revived in Park City stocks. Development work has been resumed at the Uintah Treasure property at Park City.

BUTTE, MONTANA.

British-Butte.—Placer Against Quartz Claim.—North Butte Extension.—Heinze's Difficulties.

The application of the British Butte Mining Co. for patents on about 1000 acres of placer ground just west of the city of Butte, is being opposed by Government agents, and for some time several referees have been engaged in taking testimony in Butte. The company has for more than a year been engaged in opening the ground preliminary to extensive placer mining by means of dredges and cyaniding, and to a depth of about 750 ft. the ground has been sampled and tested every two feet. Not a single blank test or sample was found throughout that depth, and in the underground cross-cuts assays show from 50c. to $24 per ton in gold. However, special agents of the Government, who claim to be mineral experts, have testified before the referees that the ground is valuable only as agricultural land, and does not contain gold. It has been the testimony of placer miners for 30 or 40 years that gold could be found in any spot over a vast territory west of Butte.

A suit of the South Butte Mining Co. against the East Butte Mining Co. and a number of the latter's lessees, for $100,000 damages on account of ore alleged to have been mined from fourteen one hundredths of an acre of ground embraced within a Great Northern railway right of way, the mineral rights to which the railroad company assigned to the South Butte Co., has been tried and submitted to Judge Bourquin for decision. The East Butte Co. owns the Oneida, a quartz location, which covers the small tract in question, and asserts title through that, while the South Butte claims under a placer title. The ground is outside the original East Butte territory, and the latter company did not assert its quartz title until forced to do so by the action of the South Butte, and the controversy resulted in a contest between quartz and placer rights. The South Butte has two claims for ore aggregating $400,000, but its own evidence at the trial showed that the total net value of the ore mined was less than $18,000. If the East Butte wins on its quartz location it will be a very important victory, as the Oneida not only covers the small bit of ground claimed by the South Butte, but also much valuable mineral ground, held under placer patents, and owned by the Amalgamated Copper Company.

F. A. Heinze is reported to have disposed of his controlling interest in the Stewart mine. It is said that those now in control of the property are preparing to resume operations. Both the Basin Reduction Co. and La France Copper Co., Heinze corporations, appear to be pressed for money, as recent checks of the Basin Co. were held up for lack of funds at the bank on which they were drawn. The La France has not paid wages for more than two months.

TORONTO, CANADA.

Opposition Interpellates Government on Yukon Gold.—Status of Yukon Holdings.

In the Canadian Parliament on May 4 Frank Oliver, Minister of the Interior, replied at length to a series of questions put by Claude Macdonell, representative of South Toronto, as to the flotation of the stock of the Yukon Gold Co. by Thomas W. Lawson and the actual status of that concern. The answers were principally noticeable for the lack of any definite information held by the Government on this subject, but some important points were cleared up. Mr. Oliver replied that the Yukon company holds placer-mining claims on the Bonanza, Eldorado, Bear, and Bunker creeks, but that as no record of production by creeks had been kept, the Government was not able to corroborate the statement that these claims had a production-record of approximately $100,000,000. Neither could they tell the area of the company's holdings, as many of their claims had not been surveyed, and they varied in size according to the regulations under which they had been acquired. The title to the claims was conditional on the performance of work to the value of $200 and the payment of a renewal fee of $15 upon each claim every year—which statement is in flat contradiction to the company's claim of absolute ownership. The Minister further stated that the total number of claims acquired by the Yukon company appeared to be 820. There is a serious discrepancy in this statement as compared with other official information recently issued by the Department of the Interior. A report on conditions in the Yukon prepared by A. H. Rowatt, embodying data obtained on a visit to the territory last fall, and bearing date September 30, states that the Yukon company had then acquired about 950 claims on the creeks mentioned.

Asked if the Yukon company had acquired the Treadgold concession, Mr. Oliver replied that he did not clearly understand the question, but that if it had reference to a right once granted to Messrs. Ewing, Treadgold, and Barwick to acquire reverted or abandoned claims, which right was afterward rescinded, his answer was "No." The Government, he went on to say, had no information as to statements appearing in the Lawson advertisements, had taken no steps to warn investors, and had had no communication of any kind with Lawson or any member of the Guggenheim syndicate with reference to the acquisition of claims. In answer to a question whether the Government was aware that the company was capitalized at $17,500,000, and that the public had subscribed for shares on the faith of statements as to the absolute ownership of claims by them, all that the Minister had to say was that as the company appeared to be operating under a local ordinance, no doubt a statement as to the amount of capitalization had been filed with the Territorial Government.

The *Canadian Mining Journal* of Toronto, which was instrumental in the suppression of local wild-cat enterprises, announces that a charge of violating the provisions of the Ontario Companies Act in connection with the Yukon flotation will be brought against the promoters.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Glass grit for grinding valve-seats can be made without danger to the eyes by hammering the glass in an envelope of old roofing tin.

Mercury may be easily scooped up with a card or envelope if a wet ring is first made around it on the table or floor where it is spilled.

Metric screw threads may be cut on lathes with inch-divided leading-screws, by the use of change-wheels with 50 and 127 teeth, since 127 cm. equal 50 inches.

Cement for cloth or leather may be made of 16 parts gutta-percha, 4 india rubber, 2 pitch, 1 shellac, 2 linseed oil. Melt together, mix thoroughly, and apply hot.

Taps broken off in castings may be removed if dilute hydrochloric acid is poured into the hole and allowed to remain about four minutes. Enough of the tap and casting are eaten away to loosen the tap.

Fine metalliferous mineral particles in suspension, which often present serious difficulties in settling, may be separated readily by passing the slime-bearing waters through compartments similar to those in the zinc-boxes used in cyanide plants, filled with coke.

Boiler scale may sometimes be prevented by putting granulated zinc in the boiler. The action appears to be an electrical one, the iron being one pole of the battery and the zinc being the other. The hydrogen goes to the iron shell and escapes as a gas into the steam, while the oxygen goes to the zinc.

Titanium-steel alloy may be produced, according to A. J. Rossi, by covering the steel with a blanket of slag, such as that from an ordinary iron blast-furnace. A suitable composition is 40% silica, 15% alumina, 35% lime, and 10% magnesia, or the slag may advantageously contain up to 25% titanic acid.

Ozokerite, one of the bitumen series, is a mineral grading from yellow to a dark brown and sometimes greenish, and may be considered as an altered form of petroleum, robbed of its volatile substance. It is used chiefly as a substitute for beeswax in the manufacture of candles, and as an insulating material in electrical machinery.

Lubricating oil should have the following qualities: 'body' enough to prevent the surfaces to which it is applied from coming in contact with each other; freedom from corrosive acid; as much fluidity as is consistent with proper 'body'; minimum frictional resistance; high flash and burning points; freedom from materials liable to produce oxidation or gumming.

The cement mill at Roosevelt, Arizona, operated by the U. S. Reelamation Service to supply cement for the construction of the Roosevelt dam, produced 10,614 bbl. of cement in February, at a unit cost of $1.81 per barrel. In comparing this cost with the price at which cement could be purehased, it should be borne in mind that there should be added to the latter the cost of freight to the nearest railroad station and the cost of the long team haul to the dam.

Decay of stone due to the action of sulphuric acid in gases escaping into the atmosphere, may be remedied by the use of baryta. The easiest way of applying this earthy base is in the form of baryta water. The dust and loose particles of stone should be removed from the surface to be treated by means of a jet of air. The baryta should be sprayed on at intervals of two or three days until the stonework has beeome hard enough to bear the application of a paint brush freely charged with baryta water. The work must be done in hot summer weather, and the solution will then penetrate a considerable depth in porous stones, after eight or nine applications. About one gallon of baryta water is required for each treatment for 20 superficial yards. Baryta water is poisonous, and precautions should be taken to protect the workmen.

Gold may not only be locked up from the action of mercury by lubricating oil, preventing amalgamation, but oils present in the ore will also hinder solution of the precious metal by cyanide. Duncan Simpson recently showed that in cases when extraction by cyanide had fallen off, it was sometimes possible to leach out a substance resembling vaseline by washing a sample with ether, after which further treatment with cyanide would yield additional large extraction of the gold-content. There are no cheap solvents for the modern lubricating oils. The use of cyanide and caustic soda to cut them is a relic of olden days when lubricants were largely made from organic fats, which are saponified by strong alkalies. The only resource for the modern metallurgist is to absolutely prevent oils getting into the ore.

Tellurium is difficult to detect with certainty when present in small quantity in ores, except by refined methods of analysis. The simple tests described in the textbooks require that particles of the suspected mineral of appreciable size be used. Messrs. Holloway and Pearse describe, to the Institution of Mining and Metallurgy, a new method which they have shown will enable tellurium in minute quantities to be revealed. The ore is crushed and mixed as for an ordinary assay and fused. The resulting lead button is dissolved in dilute nitric acid, and the filtered solution further diluted. A piece of bright sheet-lead placed in this solution will soon become blackened from the deposition of tellurium, which may be rubbed off and put into concentrated sulphuric acid in which a scrap of tin foil has been placed. On heating to the boiling point a carmine coloration in the solution demonstrates the presence of tellurium. The color disappears on cooling, but will reappear on again heating.

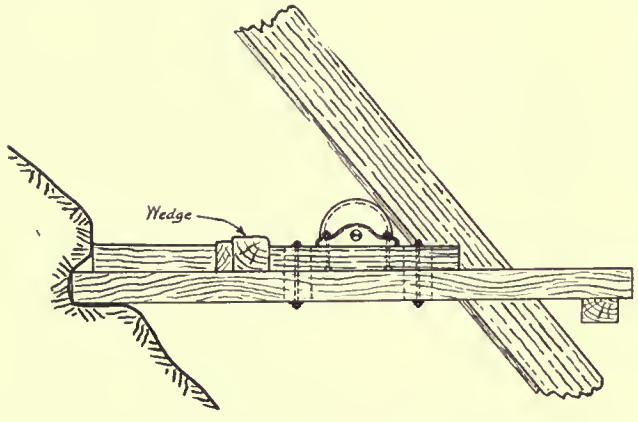
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Handy Roller for Pump-Rod.

The Editor:

Sir—Some time ago it became my lot to look after a line of Cornish pumps. After going over the line a few times I discovered some of the rollers running light, others running only on the down stroke, the lining being scarcely worn, and others carrying a heavy strain. Also in case of changing a lining I found it necessary to have a jack-screw to do so. The shaft was an incline varying from 70 to 50° for a distance of 1000 ft. Each roller was set in a cast-iron box and babbitted. The stay to carry the roller



was a piece of 4 by 6 in. on its edge, the boxes being bolted to the stays, which made them stationary.

After getting an extra pair of boxes and letting them into a piece of 4 by 4 by 30 in., I then bolted them to make them solid with the piece, as shown in the sketch. By cutting a hole near each end about 4 in. long and 1 in. wide for a ⅞-in. bolt, I made an adjustable box, strengthened by placing a block behind it set back against the ground, and spiked to the stay, with a wedge between the block and the box. The only tool necessary for setting a roller or changing a lining is a wrench to loosen or tighten the nuts on the long bolts. It could also be used to tighten the wedges when setting the roller or to knock them out to slide the roller back to change a lining.

Silver Plume, Colorado, March 23.

Sodium Cyanide.

The Editor:

Sir—The article on 'Passivity of Gold' in your issne of March 28, agrees with our experience at this plant with the two forms of commercial cyanide containing, respectively, potassium, 98 to 99%, and sodium, 125%. The question to a mill man is as follows: When he buys sodium cyanide, having in view the lesser bulk and consequent cheaper freight rate, does he actually have an excess of 25% in efficiency over the old form of potassium cyanide.

In the cyanide department of the Daly Reduction Co.'s mill, the average consumption of sodium cyanide during a period of five months was 1.35 lb. per ton of ore treated, or in terms of potassium cyanide, 1.69 lb. per ton. Trouble was found in bringing up the working mill-solutions to the desired strength, by the addition of the calculated required amount of sodium cyanide. Clean laboratory solutions of sodium cyanide titrated correctly, showing that the salt was of required purity. In the working mill-solutions, however, it was constantly necessary to add an excess of sodium cyanide above the calculated amount, to obtain the desired strength of solution..

We changed to potassium cyanide. At the present time, and after a period covering seven months, the average consumption of this salt is 1.46 lb. per ton of ore treated, or a saving over the sodium cyanide of 4 cents per ton of ore, in terms of the prices at this place. This result has been reached with the same class of ore in each case, and with the same percentage of protective alkali.

With sodium cyanide solutions, the zinc-boxes were troublesome. The zinc coated badly, and after a short time action ceased, making frequent clean-ups and washing necessary. With the closest attention our sump solutions averaged 20 cents per ton in gold. With potassium cyanide, the zinc-boxes are not uncovered more than five times a month, and an average sump solution is not in excess of 6 cents per ton.

The above has held true to a greater or less degree with ores previously encountered at Gould, Montana, and at Zortman, Montana.

Hedley, B. C., April 13.

Cyaniding Mill Pulp After Amalgamation.

The Editor:

Sir—The examination of an average pulp produced after preliminary crushing in stamp-batteries or other mills, after it has been treated by plate amalgamation, would prove that the different sizes vary as regards specific gravity and mineral composition, as they are known to do in values. In one case the following averages of sizing tests of daily samples, representing a period of 14 days, are given. The pulp after amalgamation was sized, and each size assayed, with the following results:

Mesh.	Per cent.	Dwt. fine gold.
+ 60	14.6	8.8
+ 90	16.5	7.9
+ 100	5.8	4.5
+ 150	8.5	2.9
− 150	54.6	1.2

In other words, 54.5%, or more than half, of this pulp contained only 1.3 dwt. gold. The whole was roughly classified, the coarse product re-ground and finally everything was discharged as a so-called slime into vats for cyanide treatment. The cost apparently did not justify cyaniding 1.3 dwt. product, and it was found that much visible gold, escaping amalgamation, could be arrested on blankets. These blankets were strips, 12 in. wide, fixed upon the lower ends of the plates. Possibly by careful classification, a large percentage of the total tonnage of the finest slime carrying low value, might be eliminated and treated by blanket strakes, slime tables, or automatic

frames, and thus a considerable percentage of the gold in these slimes might be caught inexpensively. The tank capacity available for cyaniding in an all-sliming process would be capable of meeting the requirements of a larger output than was at first intended without incurring the extra expense of enlarging the cyanide department. I think the difference between the first slime produced in a mill and that subsequently obtained by re-grinding is often overlooked. They are really so different that they warrant independent study. In the first instance the softer and more readily pulverized rock constituents, namely, pyrites, aluminous earths, etc., predominate while the portion re-ground has a different character and is more silicious. The question is, whether in an all-sliming process, first slimes are worth cyaniding in every case.

CYRIL E. PARSONS.

London, March 7.

Theory.

The Editor:

Sir—The word 'theory' has been so often loosely bandied about both in connection with mining training and mining work, that I venture to hope that you will find room for a few remarks about the word and its usage.

"Theory," writes John Stuart Mill—and his remarks are so pertinent that they are worth quoting in full—"in its most proper acceptation means the completed result of philosophical induction from experience. In that sense there are erroneous as well as true theories, for induction may be incorrectly performed, but theory is the necessary result of knowing anything of a subject and having put one's knowledge into the form of general propositions for the guidance of practice. In another and a more vulgar sense, theory means any mere fiction of the imagination, endeavoring to conceive how a thing may possibly have been produced instead of examining how it was produced. In this sense only are theory and theorists unsafe guides, but because of this, ridicule or discredit is often attached to theory in its proper sense."

This misconception of the word 'theory' is a common error of the ostentatiously practical school of mining engineers. It is therefore as well to point out that, though *all* theorize in a sense, theorizing in the right sense as described above is usually only the privilege of the trained; while "fictions of the imagination" are the universal heritage of the untaught, so much so that the words 'ignorance' and 'superstition' are readily associated together.

There are at least two reasons for this. In the first place, it is natural to observe incorrectly—there is a tendency for observations to be obscured by inferences, and an uncultivated mind finds it difficult to discriminate between what is inference and what is fact. As a general rule it requires training to do this with efficiency. It is true that many men are naturally clearer observers than others. The artist is a man who has an unusual power of reproducing clearly his observations of form and color, but even he usually finds it advisable to undergo some training in anatomy to correct his impressions of the human figure, one of the commonest objects of his vision.

As a rule, it may be said, the more uncultivated the observer the more unreliable are his observations. "The simplest narrative," says Dugald Stewart, "of the illiterate observer involves more or less of a hypothesis; nay, in general it will be found that in proportion to his ignorance the greater the number of conjectural principles involved in his statements." Secondly, it is difficult for an untrained mind to make correct deductions from observations. One finds such deductions as this: The main reef is rich at Reeftown. This property contains the main reef, therefore this is a rich property.

Such generalizations are becoming rarer, owing to scientific methods of sampling and the application of sound 'theory' to the results obtained therefrom. Another source of error in uninstructed minds is the attempt so often made to explain complicated phenomena by a "simpler explanation than their nature admits of."

One way of learning to observe and to think correctly is by associating with those who do so. A young engineer, starting his career by going into the field, is fortunate if he gets apprenticed to such a man, for it depends largely upon those he is taught by whether he learns sound theory or merely acquires a more vivid imagination. On the other hand, at a good mining school, instruction in the art of observing and thinking are afforded from the outset, and the students at such institutions are brought into contact with men of scientific education who theorize only in the best sense of the word and have the knowledge and ability to clear away "fictions of the imagination." Do not therefore let us give a wrong interpretation to this word 'theory' as applied to the teaching of science; and if scientific theory should at any time appear to be mere fiction, let us remember that the savage thinks the world is flat and the uninstructed observer still thinks that he sees the sun rising and setting and the stars revolving in circles round the pole.

MUNGO PARK.

Menai Bridge, North Wales, March 14.

Mill-Tests.

The Editor:

Sir—I notice in your issue of March 28, that Mr. Mark R. Lamb comments on the statement I made in an article published by you on January 25, in which it was stated that the results of preliminary tests made on small quantities of ore rarely differ more than 5% from those obtained from testing larger quantities, or in other words from 'mill-tests,' and that for this reason he is of the opinion that the mill-tests are unnecessary, the results obtained from them not doing justice to the ore, for the reason that "the larger or mill tests bear very close resemblance to the first few days' run of a new plant, when the best results are rarely expected and never obtained."

While agreeing with Mr. Lamb in the main, I think he rather overstates his case, as there appears to me a large difference between running a carload of ore

through a testing plant, the proper adjustment of which has been determined by careful preliminary work, the machinery and mechanical appliances of which have already been licked into shape by many months and perhaps years of previous running, and last but not least, the testing plant is in charge of a few experienced men who know the plant and its peculiarities from crusher to tailing-launder; as against the starting up of an entirely new equipment that has never been run in unison, by men unfamiliar with eccentricities of the plant and of each other. While it is admitted that the metallurgical results obtained from the small tests furnish data that are reliable; mill-tests furnish mechanical hints that are not procurable from the former. It is an admitted fact that no laboratory crushing can exactly duplicate the product obtained from the Huntington, the Chilean, or the stamp-mill when running under mill-conditions, and it is a wise precaution, before investing thousands in a reduction plant, to see if this difference in crushing makes any material difference in the final results.

The difference in the two classes of test being largely mechanical, it is more prominent in concentration work than in a chemical process, but even in a cyanide test it is well to check the results obtained in the preliminary tests with those obtained from leaching sand to a depth of five feet or more, and from the slime when subjected to actual filter-press treatment. While the preliminary test may satisfy the metallurgist and the mining engineer, it does not often appeal to the operator, or to the man who is putting up the money; nothing appeals to him as much as results obtained from the larger tests, the products of which are obtained from a continuous run, under mill-conditions, and large enough in quantity to be turned into cash.

When deciding upon such an important matter as the correct process and right machinery for converting the product of a mine into dividends, too many precautions can hardly be taken in gathering the necessary metallurgical and mechanical data. It therefore appears to me that before a plant of any magnitude is designed, the mill-test after the preliminary, is almost as important as the preliminary before the mill-test.

ERNEST GAYFORD.

Salt Lake, April 3.

Slime-Filters and Patents.

The Editor:

Sir—In your issue of February 1 you publish a letter written by Mr. Arthur DeWindt Foote; this letter I have carefully perused. He mentions that a friend told him that this process was in use for many years prior to my patent being taken out, for leaching chemicals. I challenge this, and would like the fullest publicity given to this matter. I had never heard of compressed air being used to keep the filtering medium porous, until I used it, and I claim to have originated it. However, of course, I am open to conviction on this point. I may inform your readers that my first experiment was with filter-cloth tied over an ordinary glass funnel, first submitting to a vacuum, and then blowing back, and I gradually elaborated on this until I finally came to the idea of building filtering-compartments in the form of a wheel. If Mr. Foote's friend will be good enough to put in print or refer me to a process using compressed air for the above purposes before I took out my patent, I shall be grateful to him.

ASKIN NICHOLAS.

Stannary Hills, Queensland, April 7.

A Theory of Ore Deposition.

The Editor:

Sir—While at a mine in Oaxaca, I read Mr. Horace V. Winchell's cheerful comments upon my article in your issue of February 22. I have neither the article nor Mr. Winchell's letter with me at present, but feel bound to explain a few points as I recollect them.

The re-arrangement of metals at and near the surface by surface waters, and shallow-seated (vadose) waters derived from the surface, the re-arrangement being due to physical and chemical characteristics such as differences in specific gravity, and in solubility under surficial conditions, is so well known that I have come almost to consider it as axiomatic. I cannot, however, enumerate the various forms of ore deposits thus brought about; but among them come the secondary sulphides, especially important in copper ores, and the secondary lead and zinc carbonates and sulphides, especially important as a result of the alteration of primary mixed galena-blende-pyrite deposits.

But my studies have lately brought me to believe that, save often in the case of the most common metals, these secondary processes operate to concentrate metals already in a state of quite extraordinary concentration. This is commonly accepted in most cases that come to mind; for example, there are few nowadays who, in a rich placer region, do not look confidently for the original source of gold in veins traversing the eroded rocks; or who, on encountering rich carbonates and sulphides of copper near the surface in a given locality, do not look for some impoverishment with increasing depth, as the ore is found nearer and nearer the primary conditions. Yet there are many cases where, if the accessible local conditions alone are studied, the derivation of such secondary ores from primary concentrations is not evident.

I may state in advance that I have come to regard primary ores in general as the result of critical or catastrophic conditions, and have been led far away from the uniformitarian theory of ore deposits which I once regarded with favor. Accordingly, I now look upon primary ores, representing a given stage of ore deposition, as having been formed in most cases within a very brief period of geologic time, and within a limited space or range of distance in which the critical conditions obtained. Hence primary orebodies (including veins) have a top, bottom, and sides. In the case of veins, as is shown at Georgetown, Colorado, the bottom of the vein-filling may be reached, while the strong unfilled fault-channel passes to much greater depths. Erosion may

therefore not be great enough to reveal the top of an orebody; or it may reveal the top, as at Guanajuato in Mexico, in which case relatively deep mining may be possible; or it may have cut down to near the roots of a deposit, in which case a mine is easily bottomed; or it may have cut down below the bottom of a deposit. During this wearing-down process the relative amount of metals carried off by surface waters and mixed with detrital deposits, and of metals carried down and re-deposited in the rocks, often in a concentrated form, depends on several factors, as I have explained in my book 'Geology Applied to Mining.' Under certain conditions a large amount of metals is continually migrating downward, keeping pace with erosion; and this migration may continue after the bottom of the original body has been reached and passed. Such ore deposits may show to the close student evidences of formation largely, almost entirely, or entirely, by descending waters; and where, as in many cases, the ores are associated with an igneous rock containing small quantities of metals similar to those found in the orebody, the conclusion that the descending waters have derived their contents from a disseminated form in the eroded rocks is natural, though I have come to believe it mainly an altogether erroneous one. This applies especially to Monte Cristo, where nearly ten years ago I described the local evidence of the deposition of large quantities of sulphides by descending surface waters. In many of the instances studied or described at Monte Cristo, there appeared to be certainly no root-deposit, and it appeared that the metals were wholly precipitated from descending waters; and since this evidence was all that there was obtainable, I stated, though without assurance, the general result to which the local evidence led. Wider regional studies have slowly decreased the weight I give to this evidence, until now (though I have never visited the camp again) I believe that the sulphides which I described represent the complete working-over of primary veins.

I have been led to this view largely by my studies at Georgetown, Colorado, in the report* on which (by myself and G. H. Garrey) Mr. Winchell may see how "ingeniously" I have interpreted the conflicting evidence of ascending and descending solutions. In this district some of the veins, containing easily bottomed ore deposits (below which there is little or no cementation of the fault-channels) bear evidence of having been deposited entirely by shallow descending waters; and if I had studied these veins alone, I should have been obliged to simply record the evidence and give the same tentative conclusions as at Monte Cristo. But studies of other veins in the same region reveal the primary ores, extending to considerable depths. In other words, the downward migration of secondary sulphides, keeping pace with erosion, has passed the bottom of some of the primary vein-fillings, while erosion is still working on the middle or even the upper part of other veins.

With these later views of mine, the main mystery of ore-concentration still remained entirely unattacked. Surface influences fit to re-arrange ores already assembled, are well-nigh universal; but ore deposits are not; ores occur in certain definite districts; and though they are mainly noticeably associated with igneous rocks, this is not always the case, nor are they associated with all igneous rocks. The distribution of ore deposits and of igneous rocks shows that the first is associated with, but not strictly dependent upon, the second. It is this main mystery that I believe I have gone far toward solving, in the explanation sketched out in my 'Theory of Ore Deposition.'

I will not go further in this letter in explaining the points raised by Mr. Winchell. In my original article I have limited my statements at the utmost to my personal experience, and I feel insecure in discussing problems with which I am unfamiliar by actual contact, and where the available recorded evidence is conflicting and confusing. My impressions of many of these problems, derived from the writings of authorities, were formerly rather more definite than at present. Until recently, for example, I have had no doubt as to the correctness of the more common explanation that the Mississippi basin lead and zinc deposits had been leached from a disseminated condition in certain sedimentary formations, in which the metals had been deposited from the sea-water; and had been concentrated locally by ordinary ground-waters. Recently I spent a couple of days underground in a great Missouri mine. I should not be justified in making any statements, much less in rushing into print, upon the bases of such brief observation, for then I should be severely and justly criticized by those who have carefully studied the region; but I was astounded in this instance at what seemed good evidence of very intense and very brief ore deposition by ascending waters, this deposition being associated with regional fracturing of the rocks, initiating faulting, and at evidence of the inactivity of ordinary ground-waters in regard to ore-concentration and ore deposition, both before and after the extraordinary event. It is a consequence of this unworthy visit to Missouri that I have privately imbibed some of the proverbial spirit, and henceforth want to be shown.

J. E. Spurr.

New York, May 1.

* About to be issued by the U. S. Geological Survey.

The production of hydraulic cement in the United States during 1907 was, according to advance sheets issued by the U. S. Geological Survey, dated March 25, as follows: 48,785,390 bbl. portland cement, valued at $53,992,551; 2,887,700 bbl. natural cement, valued at $1,467,302; and 557,252 bbl. puzzolan cement, valued at $443,998; or a total of 52,230,342 bbl., valued at $55,903,851. These figures show an increase of 21½% over the production of 1906.

The Rio Tinto Co. produced 1,906,948 tons of pyrites during 1907. Deliveries of sulphur ore were 619,814 tons. The copper produced at the mines was 21,251 tons, and the fine copper in pyrite shipped was 11,066 tons, making a total of 32,317 tons. The net profits during the last four years exceed 6¼ million pounds sterling.

GOLDFIELD, NEVADA.—II.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The story of the mines that made Tonopah and Goldfield famous is interesting, but the most picturesque story is that of which George Wingfield is the central figure. When Tonopah was discovered by Jim Butler in 1900, Wingfield was barely 21 years old. Already he had been variously a cowboy, a gambler, a prospector. In the spring of 1901 he went to Tonopah. He came thither from Winnemucca, where he had made a little money and owned some property, but being ambitious for a larger field he left a town that was only a point to punctuate the transcontinental line of the Southern Pacific, and started for the districts that were awakening the desert to busy life. He wandered from Winnemucca to Tonopah, where he went into partnership with Tom Kendall, who owned a saloon. Shortly after he joined Jack Hennessy in starting a roulette table in a room adjacent to Kendall's saloon. This gambling establishment was named the Tonopah Club. It made money fast. In three years Wingfield and Hennessy cleared $300,000. For those unacquainted with local conditions, it may be well to add that it was honest gambling, that is, there was no trickery or device to interfere with the hazard of fortune. The players took the chances of the game, just as they do at Monte Carlo. The Tonopah Club was not as gorgeously furnished as the casino by the shore of the Mediterranean, but George Wingfield ran his place just as squarely as that absurd anachronism, the Prince of Monaco.

As soon as Wingfield began to make $75,000 to $100,000 per annum, he placed the profit from the game in mining stocks and prospects. Tonopah was flushed with newly made wealth. In 1902 and 1903 the lessees on the Mizpah claim made money hand over fist. There was activity in every kind of gambling, from roulette to grubstaking. The chances of the desert were at least as good as those of the table. Wingfield got Nixon interested in some claims called the Boston-Tonopah group, situated at the back of Oddie Mtn. This was the first business deal with Nixon. George S. Nixon was president of the First National Bank of Winnemucca; he is now Senator from Nevada. Many tales have been invented to explain the first association of the two men who later became partners in mining enterprises involving enormous sums of money, but the facts are sufficiently romantic without adornment with the tinsel of fabrication. Wingfield knew Nixon when both of them were living at Winnemucca, and Nixon was known to be a man ready to back any reasonable venture. But the Boston-Tonopah was no good: it was within the mineral belt, but not in the rich ground.

Then came the discovery of Grandpa, or Goldfield, as it was subsequently christened. Wingfield's friend, Tom Kendall, had been partner with Jim Butler in grubstaking Stimler and Marsh, the discoverers of Goldfield. Kendall himself went to see their find, thirty miles from Tonopah. Two days later he stood on Columbia Mtn., which overlooks the present town of Goldfield, and directed Stimler and Marsh to examine and locate the ground to the south, now covered by the Florence and Combination mines. They broke samples from the combs of rock that appeared above the sagebrush and tested them by panning, getting no gold; then they went to the north side of Columbia Mtn. and located the Nevada Boy, May Queen, and a lot of other claims that never amounted to anything. They also located the Booth claim, at the foot of the mountain, for William Booth of the *Bonanza*, a daily paper published at Tonopah. Thus the Combination and Florence ground was not located by the first party of prospectors. This was at the end of 1902. In May 1903 there was organized the syndicate of ten as already stated. Each member of the syndicate was assessed $100, of which $50 was paid up. They sent A. D. Myers and R. C. Hart to Goldfield. Finding some ore, they located the Combination No. 1, 2, and 3 claims, the Hazel Queen, and the Golconda group of six claims, so that ten claims were taken up at this time. Subsequently Myers and Tom Murphy located the Combination Fraction.

Up to this point Wingfield played no part in the exploration of Goldfield, but when the first excitement had passed he bought (for himself and Nixon) some of the shares of the syndicate owning the Combination group, and he also purchased an interest in the first discoveries made by Stimler and Marsh, on the Sandstorm and Kendall. He had become rich, making as much as $200,000 in a single year from the roulette table and successful speculations in local stocks at Tonopah. In the early part of 1904 he bought the various holdings of Con Crooks, who was an old prospector in possession of a number of fractional interests, from a quarter to a half, in over 30 claims, including the Sandstorm, Kendall, and Mohawk, besides groups of claims called the Laguna, Blue Bell, and Conqueror. Crooks had a partner named Harry Ramsey, who now lives in opulent retirement at Berkeley. Wingfield and Nixon bought him out also, not long after they had made their deal with Crooks. Then they purchased Jim Butler's interest in the Sandstorm and Kendall claims. Thus Wingfield and his partner began to have large and scattered holdings in the Goldfield district. At this time Wingfield offered to sell Hennessy a half of all his holdings at Goldfield for $1000, but Hennessy refused it. This is authentic. It is one of the might-have-beens of desert romance. Soon after this unconscious play with fortune, Wingfield began to make money from leases that he financed, providing capital for exploring likely-looking ground. Among these ventures was the Sweeney lease on the Florence lode. In 1905 he made $350,000 from his share in this lease and then he and Nixon, who had remained his partner throughout these transactions, bought a one-third interest in the Florence group of claims. In the autumn of 1906 they obtained control of the Red Top and Jumbo for $1,200,000. It is generally supposed that in this big deal they were financed by others, but I am able to deny such a statement. They had made money enough to swing even a deal involving over a mil-

The Principal Mines Extend from Columbia Mtn. to the Right, Beyond the Town.

lion dollars. That was the beginning of the consolidation, which was organized on November 13, 1906, under the title of the Goldfield Consolidated Mines Co. The capital is divided into 5,000,000 shares of $10 each, and of these 3,535,171 have been issued. The cost of the properties is placed at $35,085,454. During the past fiscal year the production of ore had a value of $6,296,476. And these were the mines that were hidden under a sagebrush plain diversified by combs of iron-stained rock only five years before. Talk about the creation of wealth! Never was there such a sudden transformation of the waste places of the earth into a hive of human industry.

On April 17, 1906, the day before the earthquake-fire in San Francisco, the big bonanza of the Mohawk mine was cut by the lucky lessees, and during the months when the money markets of the Pacific Coast were closed by the disaster to the City by the Golden Gate, the outpouring of golden ore from the Mohawk, Florence, and Red Top mines redressed the industrial balance and started Goldfield on a career of marvelous prosperity.

In all of these events George Wingfield took a prominent part. He received royalty as owner of claims worked by fortunate lessees and he shared directly in the profits of lessees working on other claims. When only 27 years old he was doubly a millionaire. He proved alert, quick to action, and shrewd in business. When the labor troubles began, in 1906, he showed his fearlessness in facing the agitators. Once when the union tried to boycott the only outspoken daily paper in the district, *The Goldfield Sun*, which is now *The Tribune*, he and Jack Davis took copies of the paper, went into the street, and sold them for the newsboys. The proprietor of a gambling resort is apt to get into shooting scrapes and Wingfield has often had to pull his gun, but he has never taken a human life, his cool courage proving sufficient to carry him through any awkward situation. While he has shown himself reckless, as in the incident above related, he is no fire-eater like Jack Davis, who goes about armed like an arsenal. On one occasion when the miners' strike had reached a dangerous stage, someone took a shot at Jack Davis, who rushed into the local club (the Montezuma), announcing that he had been attacked by the strikers. The electric lights in the club-rooms were turned off instantly and every member pulled his gun and stood at the windows in expectation of an attack. It proved only a false alarm, but when Davis was examined it was found that he wore three overcoats and carried a gun in each of the two pockets, making six revolvers in all. Besides these he carried a bowie knife in his belt and at his back was slung a sawed-off shot-gun. This is the burlesque of the frontiersman. In such fooleries Wingfield took no stock, although ready to assert himself whenever occasion required.

For instance, there was an episode in San Francisco last September. The *Examiner*, one of the Hearst papers, in its customary way, had exploited a story to the discredit of Wingfield. A few days later, Theodore Wores, Edgar Mizner, and J. C. Wilson happened to be at Tait's restaurant. With them was Dent Robert, managing editor of the *Examiner*. One of the party mentioned Wingfield's name and Wilson spoke of him in a kindly way, the result being that a telephone message was sent to Wingfield, who was at the St. Francis, inviting him to join them. Wilson sent his automobile to the St. Francis and Wingfield joined the party at about 11 o'clock. Soon the talk drifted to newspapers, whereupon Wingfield said that he intended to start a daily paper in San Francisco. Robert told him of the difficulties and expense incident to such an undertaking, intimating that it would cost several millions. Wingfield replied that he had the money and, turning to Robert, said: "You seem to know all about the paper business." Thereupon Wores explained that Robert was the managing editor of the *Examiner*. At once Wingfield spoke bitterly of papers in general and of the *Examiner* in particular. Robert called him a liar. Wingfield struck him in the face and pulled a gun. Mizner interfered. Wingfield saw that Robert was unarmed and told him to go out and "get a gun," and he would wait for him while he did do so. Wores explained that the stores were closed at that time of night and no revolver could be purchased until the next day. So the incident closed. Thereafter the *Examiner* was silent as to the doings of Mr. Wingfield.

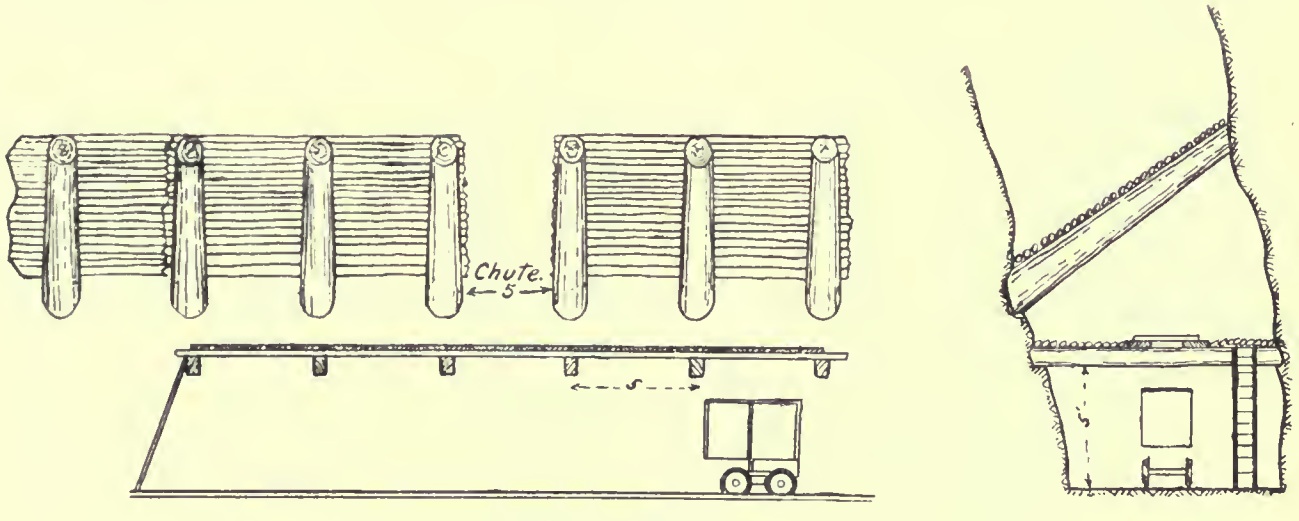
Wingfield is respected by his associates and liked by those who know him. "You cannot bluff him," they say. He is "a man of his word," generous to a fault, and possessed of the mingled recklessness and honesty that mark a few of the best professional gamblers. He is the Jack Hamlin of a later day and had he lived in the golden age of Bret Harte he would have been made as famous as the virile sportsman whose memory is enshrined forever in the story of Poverty Flat.

Another chapter in the romance of the Nevada of today is contributed by the Lockhart and Parker partnership, with which is associated the development of the Tonopah Extension and Florence mines. Alexis Dupont Parker was the treasurer of our University Club at Denver when I lived there, before 1902. He was also chief accountant for the Colorado Southern Railway. Since then he has become an important mine operator, by force of luck and Tom Lockhart. Parker is a graduate of Racine (1879); he was intended for an Episcopal clergyman, but, abandoning that avocation, he decided to learn the business of railroading, from the ground up. So he went to work on the Denver & Rio Grande railroad grade. While thus employed he met T. D. Lockhart, a prospector, who had taken a laborer's job in order to make a little money preparatory to further search for mineral wealth. They became friends. Parker believed in Lockhart and undertook to grubstake him, that is, provide funds for the search after mineral wealth. He got a clerkship in the auditor's office of the D. & R. G.; he prospered; having ability he became an expert accountant and did outside work, as, for example, for the International Trust Co. of Denver. Then he left the D. & R. G. and became assistant to the chief accountant of the Colo-

rado Southern, continuing to advance until he became vice-president and practical head of the Colorado Southern Railway. During all these years he helped Lockhart; even when a clerk on a small salary he managed to save some money to send to Lockhart, who prospected far and wide, but without any noteworthy result. In 1900 Lockhart went to Tonopah and located two claims near the Butler discovery; he was informed that he had overlapped some ground already located (the Sand Grass and Red Plume), so he moved off southward and located the Grand Trunk and C. B. & Q. claims. These were on the sagebrush plain, they showed no sign of ore of any kind, and their validity as quartz claims might easily have been questioned. Meanwhile the development on the Mizpah seemed to indicate the direction of that lode, and he began to sink a shaft through a flow of rhyolite that capped the ore-bearing formation. He started a shaft unaided; he would climb down to the bottom and fill his bucket, then climb to the surface and hoist it with his windlass. Eventually this shaft became the main opening of the Tonopah Extension mine and cut ore at 237 ft. In March 1902 Charles M. Schwab bought the Tonopah Extension for $75,000. For several years previous Parker had ceased to contribute to the expenses of Lockhart's prospecting, and legally the latter was absolved from paying his partner any portion of this stake, but he lived up to the spirit of their arrangement and handed $37,500 to Parker. They call Lockhart mean at Goldfield, and he is thrifty enough in all conscience, but his sense of honor must be far more developed than that of many more generous men. He is the type of the canny Scotchman who is as close-fisted as he is honest. After making money by the sale of the Tonopah Extension, Lockhart went to Goldfield and acquired mining property. He got hold of the Florence, paying $7000 down for a part, with an option for $25,000 on enough more of the mine to give control. Wingfield and Nixon took a lease on the Florence, and the royalty paid by them more than enabled Lockhart to complete his purchase. Soon after making this deal Lockhart overheard one of the owners chuckling over having got the best of him, but he was confident in his opinion of the value of the mine. He told Parker about it, informing him that he need not come into the deal unless he wanted to do so. Parker replied that he would share equally with him in all his ventures. He did well. The Florence has produced $3,000,000 altogether, and of this the royalty to Lockhart and Parker has amounted to fully $375,000, as owners of slightly more than one-half of the stock of the Goldfield-Florence Co. The mine is still young and is destined to add largely to the output of the district.

THE 'CHINAMAN' ORE-CHUTE.

An ore-chute with a peculiar bottom to obviate the difficulties of jamming at the doors and of sudden 'spills' or rushes of ore, which may swamp a car and cause delays until the track can again be cleared, is in use in Western Australia, under the local name of a 'Chinaman.' Its construction is clear from the accompanying cut, giving longitudinal and cross sections. Beneath the bottom of the ore-chute, where it comes to the line of stulls above the gangway or level, is a long platform or deck, supported upon sets of timbers at a convenient height above the track. This platform extends a distance of 10 ft. on either side of the chute. Along the central longitudinal line of the platform are sliding or drop-doors at intervals. The ore spills from the chute and spreads out upon the platform until the angle of rest for the pile is attained, which prevents the possibility of more ore running out. The ore is then drawn through the doors in the platform to the cars below.



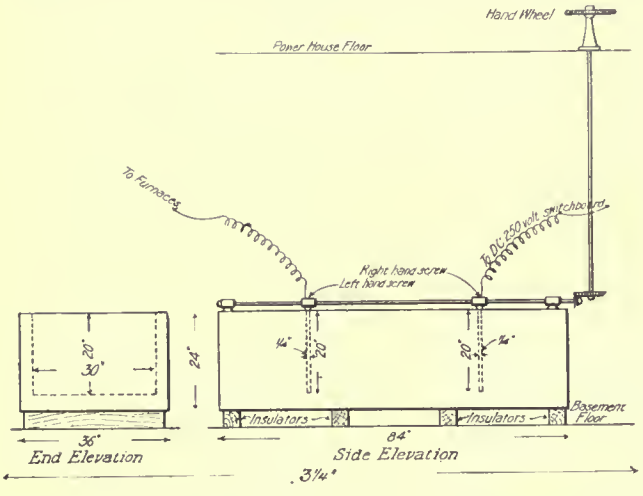
The Chinaman Ore-Chute.

A concrete trestle is a somewhat novel type of structure built across the Salt river, in Illinois, by the Chicago, Burlington & Quincy railway. The structure is 477 ft. long, with six-pile bents spaced 14 ft. apart, and with an average height of 10 ft. The piles are of re-enforced concrete, 22 ft. long, and were driven by a pile-driver with a 3000-lb. hammer falling 24 ft. The piles are all vertical and are capped by deep concrete cross-girders supporting the slabs which form the floor or deck.

Re-enforced concrete lime-kilns in Europe, built without fire-brick or other inside lining, have withstood for several years temperatures from 2200 to 2500° Fahrenheit.

THAWING TAP-HOLES ELECTRICALLY.

A method of thawing out frozen tap-holes of copper blast-furnace fore-hearths or settlers, by means of an electric arc, has proved a great economy at the British Columbia Copper Co.'s works at Greenwood, B. C. Keeping matte tap-holes open in large settlers, particularly where the matte produced carries enough copper to chill readily, is a difficult matter, the matte freezing ahead of the bar as it is driven in where what Mr. Hixon calls 'muscular metallurgy' is employed. Thawing by electricity is not new, but details as to methods of operation, current strength, etc., are not readily accessible. The scheme is as follows: Electrical energy to operate the works is received at 2000 volts alternating current, but for



electric haulage this is transformed by motor-generators to 250 volts direct current. The current for use in thawing should be of low pressure and large quantity, and therefore connection is made from the direct current switchboard into a water rheostat, adjusting the voltage to what may be required by the distance between the plates which receive the incoming and outgoing current, as shown in the accompanying sketch. The adjustment is quickly secured by turning the longitudinal rod, upon which there is a right and a left-hand screw, thereby drawing the plates closer together or moving them farther apart with corresponding variation of resistance. For convenience the tank is placed out of the way in the power-house basement and a mortise-gear operated by a hand wheel from the level of the power-house floor, is employed. At the blast-furnace the wire is attached to a carbon 1 in. diam. by 30 in. long, and this being inserted into the frozen tap-hole creates an arc which quickly melts everything ahead of it, the only trouble being to know when to stop and avoid a 'runaway.' An important point is that the operating workman should wear a mask and very dark goggles, otherwise there will be serious injury to the eyes and the skin of the face. In making connections the positive side only is connected to the carbon stick, the negative being grounded through the settler.

A marco de plata is a weight for silver formerly used in Mexico, equal to 8 Spanish *onzas* or 4608 *granos* (7.3995 oz. troy). The *marco de oro*, applying to gold, contains 4800 *granos*.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING CLAIM—PARTNERSHIP—BREACH OF AGREEMENT—FRAUD.

Under an oral agreement one person was to locate and mark certain mining claims and prepare the notices of location, and the other parties were to have such notices duly recorded at their own expense. This agreement made the parties partners engaged in dealing and in working mining claims. The first party proceeded to locate the mining claims, prepared the necessary notices, and delivered them to the other parties. The parties as such partners proceeded under the agreement and engaged in dealing in and working mining claims. The second parties fraudulently withheld all the notices from recording until after the time for recording the notices had expired; they thereupon, and after the expiration of such time, re-located all such mining claims for their own benefit. In an action by the first party to recover his interest in such claims, the Court held that all such persons became partners for mining purposes from the time of the original agreement, and were all bound thereby; that the action of the second parties in failing to record such notices within the time and perfect such location, and in re-locating the claims, was for the fraudulent purpose of cheating such first party out of his half interest; and that the first party was accordingly entitled to recover his interest in all such claims.

Cascaden *v.* Dunbar, 157 Fed. 62, Oct., '07.

COAL LANDS—ENTRY AND PURCHASE.

There is nothing in the coal land statute intended to prevent either individuals or corporations from acquiring any amount of coal land which it may be possible to pay for or secure. It is only meant that neither an individual nor corporation, either by direct entry in the grantee's own name, or indirectly by procuring an entry by an agent or servant, shall take from the Government more than the limited quantity. An individual having exercised the right to entry may buy of others by ordinary purchase as much more as he pleases; but he cannot acquire another acre from the Government. If he does so, either by direct application in his own name or by employing another to make an entry and then convey to him, he thereby becomes involved in conspiracy, perjury, and fraud. The statute prohibits the right of pre-emption but not of the title to the land, though it may be but equitable.

Pereles *v.* Weil, 157 Fed. 419, Nov., '07.

DAMAGES FOR TRESPASS IN TAKING ORE.

Where a person in the honest belief that he was in the lawful exercise of his right, entered upon the premises of another and removed ore, coal, and other products, he could only be held liable in damages for the actual value of such ore, coal, and other products in their original place. But a person who wilfully and intentionally took ore from the property of another, was held liable to the owner for the full value of the property at the time of such taking, without any deduction for the labor or expenses incurred in removing and marketing the same. Such wrongful taking would not divest the owner of the title, and a third person purchasing such coal or ore with knowledge that it had been so wrongfully taken, was held liable to the owner for its conversion.

United States *v.* Ute Coal & Coke Co., 158 Fed. 20, Dec., '07.

MINING LEASE CANCELLATION.

A mere delay in paying rent or commutation money and failure to begin operation at the time stipulated in a mining lease, was not sufficient ground for the cancellation of such lease before the expiration of the term, where it appeared that the lessee was ready and willing to pay the rent and perform the covenant to open and operate the mine.

Pheasant *v.* Hanna, (W. Va.) 60 Southeast. 618, Feb., 1908.

THE RIGHTS OF THE MINER.

Written for the MINING AND SCIENTIFIC PRESS
By THEO. F. VAN WAGENEN.

To anyone who is attracted by the study of human nature and the phenomena attendant upon the advance of civilization, an examination of the mining laws of the various nations of the world will be most interesting. They are a curious mass of statutes. Until comparatively recent times they appear to have been based on the idea that the miner, by the nature of his occupation, must be a dirty and disagreeable person, and that his business was of such an objectionable kind as necessarily to make him an undesirable member of the community, against whom society needed special protection. Of course, it must be admitted that the miner of the past rarely took a bath. And, passing the most of his waking hours underground in damp, dark, and dangerous places, there was some warrant for differentiating him from the ordinary surface laborer. And as mines had a habit sooner or later of caving in, carrying death and destruction not only to those underground, but to dwellers above them on the surface, his trade naturally acquired a bad reputation.

In addition, mining from the first was recognized as an occupation that interfered seriously with the assumed natural rights of property, as the phrase was originally understood. Real property has always been land—the meadow, the hillside, the enclosed field, the homestead. From time immemorial, when title to such was acquired, either by conquest, or by gift from the conqueror, or by purchase, the possessor was supposed to hold, not only the surface as defined by visible boundaries, but all under it to the mysterious depths, about which little was known. And when people came along who wished to explore those depths, who made holes into which cattle and even human beings occasionally disappeared, who left on the surface unsightly piles of rubbish, and whose activities often resulted in the sinking down of the surface, to the inconvenience or damage of those who had theretofore dwelt securely upon it, society, as represented by both landlords and tenants, became properly scandalized and demanded protection and relief. Probably it was some such train of circumstance that started the idea expressed by the word 'royalty.' The king was appealed to against the miner, and the latter was perhaps given to understand that the former, by reason of his position, was the real owner of all unseen things below the surface, as well as the guardian of the visible world, and that underground material must not be taken away without his permission, and without giving him a certain portion of it as the royal perquisite. Was he not the King, the representative on earth of the Deity? Later, when the supposed divine right of rulers came to be questioned, and mining as a desirable and useful industry was recognized, the right to authorize mining operations passed from the hands of rulers to those of legislature and landed proprietors, excepting as to the precious metals, which naturally fell into the category of 'treasure,' because they could be made into money, the manufacture of coins being held even today as the exclusive prerogative of governments. In due time this idea will also pass, and when it does the word counterfeit and the occupation of the counterfeiter may become not only respectable but laudable. For if he is to be commended who makes two blades of grass grow where before but one flourished, how much more the one who produces two bright dollars where only one had previously existed, provided of course that the new coin be as genuine as its model. But perhaps this is going too fast for the conservative reader.

The miner was at first compelled to pursue his calling under the distinct disapproval of the community. Later he was allowed to operate under a heavy license, and with the condition that a considerable proportion of his output of metal or coal was given to the ruler in return for legal authority to work. Still later the landlord, becoming even a more potent individual than the King or emperor, succeeded to most of these claims, and 'royalty' became 'tribute,' while the right to prospect was retained as a privilege to be granted only by the Government, for the consideration of a license fee. And today, in most parts of the world, except in the western States of America and Alaska, the miner has to pay down hard money for a license before he can even search for valuable outcrops of mineral, and in all of them, with the same exception, he cannot mine and produce the metals without giving up a certain portion of his output either to the governments or the landlords or to both. Such also used to be the situation with the farmer, the hunter, the fisherman, the woodman, and is so still in many old-fashioned and backward communities, and in a few that consider themselves quite modern and up to date; but generally these toilers are nowadays expected to give back only a very small part of the results of their labor, and in an indirect way, so that the old principle of the inherent right of the temporary possessor of a tract of God's green earth to make everyone who labors upon it contribute to his support, and maintain the dignity of his position, has passed into the hands of legislatures, and is so thoroughly recognized as a proper community matter as to be unobjectionable. The farmer no longer protests against taxes, he acknowledges the reasonableness of the theory of riparian rights and stumpage, and he submits gracefully to the dogma of 'eminent domain' when a railroad wishes to lay its tracks across his wheat-fields. But how would he enjoy being compelled to buy a license as a perliminary to locating a new farm on the public domain, or to give to the Government, after he has selected one and brought it into productiveness, from 2 to 10% of his crop annually in perpetuity, in addition to ordinary taxation. Yet the Canadian, Australian, South African, and New Zealand miner is forced today to do both of these things, while in Mexico and all Spanish-American lands, though the right of prospecting and search is free, the principle of a government royalty is maintained, even though the Kings and Majesties have been kicked out, and Presidents and Excellencies substituted. In old Europe, where the battle for human rights has been going on for a thousand years, the landlords still collect heavy

tribute from the miner; the fisherman or hunter is a poacher unless he owns the water or the land where he searches for his food, and the vast majority of farmers pay rent. It will be many a long day before the world as a whole will graduate from the idea that certain of its inhabitants, by the chance of birth or fortune, are entitled to enjoy the assumed luxuries of idleness at the expense of others. The fundamentals of the principles of slavery die hard.

But to return to the miner. Is there anything in his occupation that should warrant the legal disabilities that, until recently and except in our own country, he has borne. We have now the profession of mining engineering, and the majority of these professionals among the civilized nationalities are men of genuine merit and ability, with broad human sympathies, who do not look down upon the actual miner engaged in hitting the head of a drill, who have a genuine love of their occupation, and no sort of repugnance to soiling their clothes or hands. Still further, most of the real miners themselves take a bath at least once a week, and change their clothes with astonishing regularity every Sunday morning. The world is moving, and the time has come when an enquiry as to the rights of the miner is in order, not as a matter of sympathy for his condition, but because it has at last become evident that he is a most necessary and valuable member of the community, and that it will pay us all, in good hard dollars, to see that he gets his dues.

At the present stage of civilization it is abstractly held that the rights of a human individual bear a distinct relation to the benefits he can contribute to the community at large, and are bounded only by the similar rights of others. Thus even a trust may put its hands into the pocket of the commonwealth and abstract a certain portion of its contents, provided it uses the values so obtained in the main for the general welfare. I do not say that this right is legally admitted, but opinion is tending in that direction, and the fact is recognized that individuals who have unusual ability in any line of activity, commercial, artistic, or even cogitative, have more and broader rights than those less favored by nature. What, then, are the rights of the miner? Before this question can be answered the individual himself must be clearly defined and catalogued. I would place him under four heads, as follows: the prospector, the laboring miner, the mining engineer, and the mining investor. This list excludes the promoter and the share speculator, neither of whom may be said to have any rights that are worth mentioning in this discussion. Let us take up each class separately, and consider whether the existing laws of the most advanced nations are such as to afford each the opportunity to do his best for himself and the community at large.

The Prospector.

This individual is at the basis of the mining industry. He is the man who is willing to go out alone or in pairs, with his pack animal and camping outfit, and search the face of nature for evidences of hidden wealth. Let us not confuse him in our minds with the claim locator or 'pegger,' as our English cousins call him, for the latter is merely one who makes a hurried trip to grab vacant ground in the vicinity of a discovery already made or reported to have been made. The true prospector is a pioneer, a man with an instinctive desire to get away and stay away from society, and enjoy solitude and nature. He is always something of a naturalist, like the bug-hunter or the rock-sharp, more or less of a vagabond, and often a shiftless and eccentric party. But he has a consuming curiosity as to nature along his special lines, and a vivid imagination. He is the only kind of a man who will, of his own volition, take the trouble to go over the hillsides carefully and with observation, and, when he finds what he considers to be indications of mineral, stop, and with painful effort that you and I would not put forth, dig and sweat and undergo hardships and privations, in the hope of bringing into actuality the dream of his imagination—a bonanza. His life is generally little better than a succession of disappointments, for out of a hundred prospects where he does a month's or a year's work, rarely more than one responds to his efforts. Nature is prodigal in allurements, but very stingy in grand performance. Of the millions and millions of little threads of mineral that crop out on the hillsides of the globe but an insignificant proportion will ever pay to follow to the depths. The prospector is the one class of individual who will voluntarily take these overwhelming chances. He always believes his vein is going to widen out and become richer in depth, and it is this sublime confidence in luck that leads him on through the disappointments of his life.

Now the prospector requires three things from the community in which he operates, namely, (1) freedom to wander and search and locate mineral ground without being taxed for his activity, (2) laws and regulations covering the acts of location that are simple, inexpensive, and free from technicalities, and (3) a claim of such size and nature that he can easily sell it. For he is never a man of means, his education has usually been sadly neglected, and he is in no sense a miner or workman. These three conditions seem to me to require the absence of any such thing as a prospector's or miner's license, the existence of a location law that is of the simplest kind, with which the most illiterate and careless may comply, and a claim carrying with it the right to follow the ore downward indefinitely, for the latter is the only kind of a claim that he can sell. In support of these views attention is called to the fact that the prospector does not exist in countries whose mining laws do not expressly provide all these conditions. The western part of the United States and Alaska are today almost the only regions of the world where these rights are given him, and within them he flourishes by the thousands. You cannot find him in Texas, where there are hundreds of square miles of unexplored but very promising mineral lands, for the United States mining law does not apply in that benighted region. When the British Columbian law was similar to that of America he poured across the line like an invading army and found everything

there that has been found to date, but when it was altered so that a license was required and underground extra-lateral rights were taken away, he disappeared. His tribe by the thousands are wandering over snow-clad and ice-bound Alaska and finding new districts almost every month, but they stop at the 142nd meridian as if it were a dead-line. There is not a prospector in the whole of the great British Northwest. Down in Arizona and New Mexico they wander over the deserts and through the rugged mountains, finding new mines almost weekly, but not a man can be induced to cross the international boundary into Sonora or Chihuahua. I have spent the most of the last three years traveling through Mexico, from the Rio Grande to the Isthmus of Tehuantepec, and have yet to run across my first prospector.

In Canada, Mexico, Australia, South Africa, and other parts of the world, there are claim locators, denouncers, peggers, and mineral-land appropriators operating under other names, who occasionally by pure accident run upon a new deposit of ore, or who acquire and explore lands in the vicinity of such an accidental find, but as for real prospecting in these lands, there is none in progress. The silver mines of Cobalt, Ontario, were found by railroad graders in the prosecution of their daily task. It was a wandering Boer who noticed and tested the outcrops that have made the Transvaal so famous. The Klondike was discovered by American prospectors who believed they were on American soil. Since the region was determined as Canadian territory, they have mostly departed. The progress of discovery in Australia is so extremely slow, though the country is rich in mineral resources, that the various State governments offer a reward for the location of new districts, and even provide a small government stamp-mill at new camps, to test the ores. Yet there are but few prospectors in the land, and those that do so call themselves are a lazy and worthless lot as a class. But the American prospector has been given a 'square deal,' and in return he has laid broad and deep the foundations of a metal mining industry the like of which has not existed before, nor does exist in any other part of the globe.

The Miner.

The various organizations to which the majority of working miners now belong, represent the efforts of the class to secure for themselves the opportunity to realize a comfortable existence. There is no question of their right to combine for this end. And thinking people who observe the growth of the unions will not condemn the system because it brings some undesirable citizens temporarily to the front of the stage, or because wrong and even crimes may here and there be clearly traced to their membership. All human effort, when operating through organization, will inevitably go wrong to some extent, while yet resulting in a general steady improvement of conditions. Probably the most convincing example of human ability to err when acting in mass is to be found in the history of the Church. Yet we do not blame religion for the hideous crimes and wrongs that have admittedly been committed in her name. The movement to secure better conditions in the life of the laborer is in its infancy, but is rapidly advancing, and its progress cannot be stayed. As far as the miner is concerned, mining laws affect him but little, except as they provide for his safety and for the security of his wages.

The Engineer.

The relations of the mining law to the activities of the mining engineer are of small account. The latter is (or should be) but a specialized business man, and he must take care of himself, either individually or through the numerous engineering societies that exist now in all civilized communities. Perhaps the greatest disability he suffers under is the ease with which the evidence of his technical training may be counterfeited. Anyone in these halcyon days may write or print M. E. or E. M. after his name, without incurring legal penalties or meeting much censure from any source. This is not so much of an injury to the profession as it is to those who purchase professional services. The clients of the doctor and the lawyer encounter the same species of misrepresentation, and it is one difficult to prevent. At any rate, it cannot be prevented through amendments to the mining laws.

The Investor.

This individual, whether belonging to the class of small or large capitalists, depends wholly on the mining law for the quality of his title, and has a right to expect that legislatures will provide such a body of statutes as will give him all protection possible consistent with the general rights of the community. The various mining laws of the world have for their main object the definition of the boundaries of the mining claim. There are but two systems in practice, one of which provides as such boundaries vertical planes extending indefinitely downward, while the other requires that the apex or beginning of the mineral deposit must be within the surface lines of the claim, after which the owner has the right to follow it indefinitely downward on its dip, no matter where it leads him. Thus in one case a grant of a distinct part of the crust of the earth is given, while in the other the grant covers the deposit, together with certain surface rights. Considered wholly by itself, and from the standpoint of the investor, the principle of vertical bounding-planes is entirely right, and the principle of extra-lateral underground privileges is entirely wrong. There is absolutely no case at all for the latter until the general rights of the community come up for consideration. Then the scene changes instantly and completely with all who have arrived at that stage of civilization in which the welfare of the commonwealth is admitted to be paramount to that of the individual. For a community segregated as a State, and in possession of a part of the globe, has the right to insist (against the interests of its individual members) that in the main its lands and waters be put to the best uses that they are capable of. This means that the bulk of the areas suitable for the production of food shall be used for that purpose.

and that no unduly large part of it should be retained as private pleasure reserves: that roads should have the right of way over and through anything, if public advantage is thereby to be gained; that water-ways must not be blocked or made less valuable by riparian rights; that the water of streams capable of producing power or of irrigating waste lands is community property; that forest reservations are in the same category, and finally, that the community may in certain instances be as deeply interested in the development of its underground mineral resources as it possibly can be of any of those that are apparent on the surface, and has the same right to insist that in such cases the interests of the individual must be subservient and secondary to those of the State.

But the underground world is an unseen and unknown one. An inspection of the surface will rarely exhibit the possibilities below. Even where there are strong indications of hidden mineral wealth the best science of the day cannot reveal its extent or give an accurate statement of its value. On this account mining is generally regarded at present as an extra-hazardous occupation, into which only people of a venturesome or specially enterprising nature, or those who have plenty of money to lose, will enter. And, if we except coal and iron mining, there is certainly some warrant for the belief. But before a mine can be developed and worked it must be discovered. There are no instances on record of capitalists, business men, or scientists finding deposits of the metals except by pure accident. This is the work of a special class, namely, the prospectors, and no mining law can result in the uncovering of the hidden wealth of a country that does not provide for this class an adequate reward for their labor. The occupation of the prospector did not exist until the principle of extra-lateral underground rights was invented.

As for the investor, he is a man of more or less means, education, and business training, and is capable, if he exercises the simplest kind of prudence, of protecting himself against the dangers that exist in underground titles under an apex claim. After 35 years' experience under the American, English, and Spanish laws, the writer is deeply impressed with the belief that most of the cases of extensive litigation that have arisen in the past under the provisions of the American law, have resulted from the efforts of unprincipled men to acquire possession of property already proved valuable by others, or from carelessness on the part of investors. There are, it is true, a number of situations occurring under an apex law that can only be settled by the courts, or else by popular action taking the form of tacit understandings arrived at by a community. A well known instance of the latter is the abolition of the principle of extra-lateral rights at Leadville. This conclusion was reached in the face of the written law, and the example has been followed in several other Western districts where the nature of the mineral deposit was complex and hard to fit to the letter of the law. As for the majority of other questions, they have been passed upon by the courts, and a body of decisions and rulings has gradually come into existence so as to cover almost every problem that can arise. The mining investor therefore has but himself to blame if he finds his title, after purchase, a questionable one. Good legal advice should have been sought before the trade was made. To charge his misfortune to the law is not reasonable. Nor is it any more reasonable to seek the repeal of the apex system because of the possibilities of subsequent uncertainty as to title. For the apex and its following rights constitute the reward of the prospector, and it is of the utmost importance, and the greatest general good to the community, to have all the mineral resources of the State discovered as quickly as possible.

The Mining Law.

An impartial examination of the history and statistics of the metal mining industry (excluding perhaps that of iron) will show unmistakably that, considered as a whole, it has never paid, and is not now paying. A considerable number of properties in numerous localities all over the world are yielding dividends to their owners, and may be expected to continue doing so indefinitely. A few exceptionally rich, or large, or advantageously situated districts, are prosperous, and there will doubtless always be such. But when the real internals of the occupation are examined from a cold-blooded business standpoint, the conclusion is forced that the annual crops of gold, silver, tin, copper, lead, zinc, and quicksilver cost, as an entirety, when they arrive on the market, considerably more than they will bring in money or its equivalent. Just what is the excess of expense is impossible to determine. It varies in different countries and districts, and from year to year. The many improvements that are continually being introduced in the methods and tools of the industry appear to have borne little fruit in the matter of reducing the ratio of costs to selling value, which is no doubt due to the fact that all such improvements are immediately followed by the production and treatment of lower grades of ore, on which the possible margin of profit is smaller.

Doubtless at this point the reader will smile and say that my idea is ridiculous. How could an occupation that has advanced and spread with such marvellous rapidity during the last fifty years, have accomplished such progress under such apparently fatal conditions? It does seem unreasonable. We know that the annual output of these metals from the mines of the world was less than $200,000,000 thirty years ago, and that it came from comparatively few localities, while today it is over $1,000,000,000, and almost every nation on the globe turns out some. We also know that the industry pays the wages of a vast army of unskilled and skilled laborers, the salaries of numerous highly trained mining, mechanical, and metallurgical engineers, financial managers, secretaries, accountants, surveyors, assayers, chemists, draughtsmen, etc., and in addition supports a great number of factories producing machinery, explosives, tools, and general mining supplies.

Yet there is much to be said for the position taken. If we consider the nature of mining as an occupa-

tion, and of the metals as articles of commerce, we find that there are some very unusual features connected with both. The inherent peculiarities of the business of underground exploration has been already referred to. As to the metals, they cannot be eaten up like the crops the farmer annually produces. They cannot be burned up as are the products coming from the coal mine, the forest, or the tobacco field. They do not wear out in a year or so, as does the output of silk, wool, cotton, or jute. In fine, they are in a measure unconsumable, except as to such insignificant proportion as is used in certain of the chemical and other allied arts.

The result is that the products from the mines are highly desirable substances for the world in general, even when those engaged in the business of taking them from the ground are doing so at a loss. It is this fact that makes mining communities so prosperous and active, in spite of the actual losses of a majority of the operators. It is the most attractive, alluring, and promising of all industries connected with the production of raw material, because we always hear of the great fortunes made by the few lucky ones, while the story of the innumerable failures is never known outside of their immediate vicinity, or, if known, is promptly forgotten by a thoughtless and optimistic world. Yet it is also the most hazardous. Neither education, intelligence, judgment, industry, capital, nor experience, nor a combination of all of them, will positively insure success.

It is true that some of the articles of commerce that are made out of the metals disappear almost as readily or rapidly as food and fabrics, such as edge tools, paint, etc., yet in the main the metal crop may be considered a cumulative one, of which at least 50%, and probably over 75%, is converted into articles like machinery, buildings, power-transmission lines, etc., which yield a profit annually for years to their owners; or like coin, jewelry, plate, etc., which may always be turned into money without serious, or perhaps any, loss.

Mining laws then should be constructed with regard to the inherent peculiarities of the business of mining, and should not be patterned after statutes devised to provide merely for the safe and simple tenure of ordinary lands. When that is done, and the mines are of good average quality, operations under them will be to the general benefit of the community. A nation possessing a mineral belt within its border has been given a wonderful and important asset, but it must be rightly used. How? Mainly as a lure. No industry, in spite of its individually unprofitable nature, brings population so quickly, and produces so rapidly a raw material that serves as a basis for the inauguration of other branches of commercial activity. With the metals available in quantity, every other industry that is warranted by the climate, the soil, and the environment, springs at once into vigorous life. If, then, a community has mines, its future is assured if they can be brought into operation. What is wanted is their product, regardless, if necessary, of the cost of getting it. It can be secured in one way only, to-wit, by making the conditions of the business such that the industry will attract that class of men who, by temperament, by the exigencies of their environment, or by other circumstances are disposed to take chances, or who instinctively prefer a gamble to any other method of making their way in the world. Of these, there are a large number, and they can always be attracted by the proper kind of laws.

Most of the mining laws in existence have been framed on the theory that metal mining was an intrinsically profitable industry, or that it could be made one in a very short time. If I have shown that this is not the case, and not likely to be for a long time, until perhaps the era of the perfect electrical ore-finder arrives, it will become evident why certain parts of the globe that are known to be rich in metalliferous minerals are but small producers of the same.

A horse can exert, with reasonably good footing, a pull equal to $^1/_{10}$ his weight at a speed of 2½ miles per hour for 10 hours per day for 6 days per week and keep in good condition. On this basis, a 1500-lb. horse would develop 550 foot-pounds per second, which is the conventional horse-power of engineering calculation. The maximum draft of a horse is about half his weight, although horses have been known to exert a pull of two-thirds their weight. Most horses can exert a tractive effort equal to half their weight, at a slow walk for about 100 feet.

The Prospector.

Owing to the large number of specimens forwarded to this department, it has been found necessary in future to make a charge of 25 cents to subscribers for each determination, and $3 to non-subscribers.

The rock sent by J. C. S., of Jerome, Ariz., is serpentine.

The sample sent by H. T. W., of Mendocino county, Cal., is calcite.

A specimen of diorite-gneiss was received from C. A. M., of Nevada county, California.

F. H. C., of East Auburn, Cal., sends: No. 1, chromite; No. 2, chalcopyrite in quartz rock.

E. D. L., of Rawhide, sends: No. 1, gold-bearing quartz in a hornstone, somewhat brecciated; No. 2 is of the same nature.

There is nothing to indicate nickel in the specimens sent by W. S. L., of Silver Peak, Nev. The green color is due to copper.

The samples from Goldfield marked D. F. are: No. 1, quartzite, apparently formed from a rhyolite; No. 2, hornblende-biotite dacite.

The rocks from Rosebud, Nev., marked A. E., are apparently altered and silicious phases of rhyolitic or andesitic rocks. No. 1 and 2, rhyolitic tuff; No. 3, quartzite with pyrite; No. 4 and 5, altered rhyolite; No. 6, hornstone or chert; No. 7, quartzite; No. 8, hornstone.

REFINING AND SHAPING COPPER SIMULTANEOUSLY.

An electrolytic copper process for the simultaneous refining of copper and shaping of the finished product has been introduced by the firm of Sherard Cowper-Coles & Co. in England. The usual current density employed in the new process is 200 amperes per square foot of cathode surface, the voltage at the terminals of the depositing cell being 0.8. To enable finished products to be made direct in one operation from crude copper by electro-deposition, it is necessary to greatly increase the rate at which the copper is deposited, as compared to the rate at which it can be electrically refined, otherwise the process would be too costly for practical purposes. Attempts have been made from time to time to further increase the current density by using mechanical means for keeping the copper smooth during the process of deposition. The Cowper-Coles centrifugal process is distinct from any of these, inasmuch as it consists in revolving the mandrel on which the copper is deposited at a certain critical speed. The result of revolving the mandrel at the comparatively high speed necessary for the proper deposition, using a current density of 200 amperes per square foot, is that every molecule, as it is deposited, is burnished or rubbed down so as to produce a tough fibrous copper. The usual order of things is thus reversed, the present practice being to put mechanical work into a mass of copper instead of treating each molecule as it is deposited. The centrifugal action enables very impure solutions to be used, as the impurities are thrown off by centrifugal force and the rubbing action of the electrolyte, thus preventing the formation of nodules. The makers claim that the copper refined and manufactured into sheets or tubes in one operation is of a hard nature, similar to that which is cold rolled, and that the process is at least ten times faster than any existing electrolytic process; that a high current can be employed; that there is no risk of lamination, as no burnisher is employed; that the plant is simple; and that anodes of very impure copper can be used as compared to the anode copper used in other systems. The process was recently applied to the production of large copper cylinders for printing purposes in the textile industry. The mandrel, or cathode, is driven at the desired speed by means of a belt and pulley. The anodes are cast copper, suspended on a copper ring. The cathode connection is made by means of a mercury cup placed on top of the driving spindle. The copper cylinders are made quite thin, about $^1/_{32}$ in. thick. A roller is caused to traverse the surface of the deposited copper, so as to slightly stretch or expand it. After the roller has passed over the copper once or twice the cylinder can be easily drawn off. It is claimed that copper obtained by this process gives a remarkably high tensile strength.

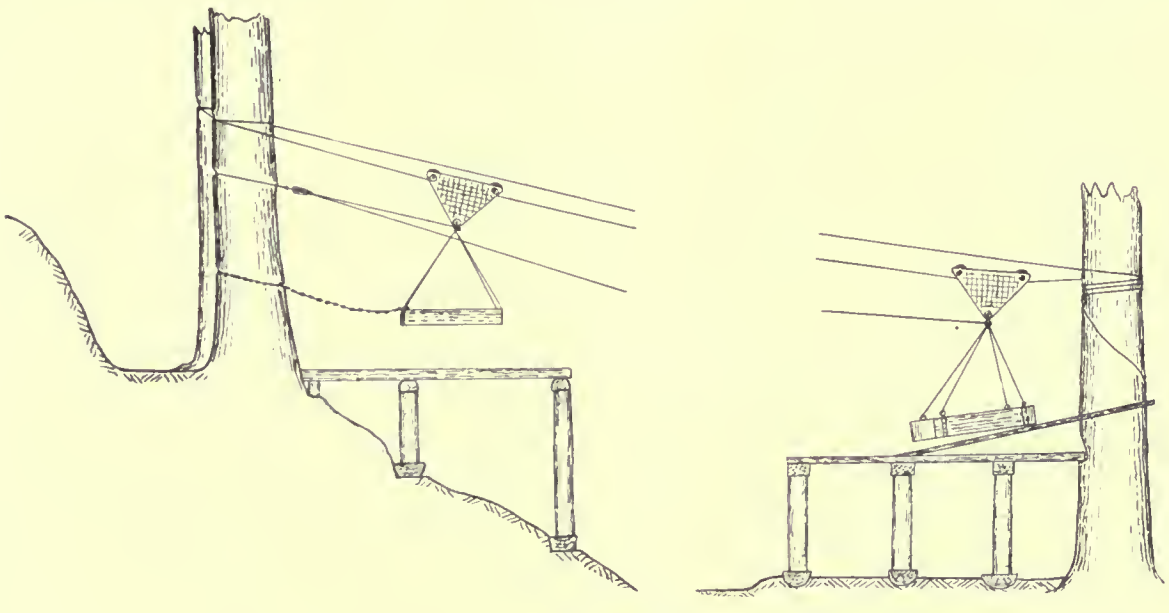
Rift in rocks is an obscure microscopic foliation which in any particular mass, as of granite, diorite, and many other crystalline rocks, will be persistent in one direction, along which the rock will split most readily. The 'grain' of the rock is a still more obscure foliation usually at right angles to the rift, although that will vary with different rocks. The rift and grain may often be easily distinguishable by the eye on clean weathered surfaces, although at times it is quite invisible. Advantage is taken of these lines of weakness in laying out quarries. By blasting by what is known as the Knox system, that is, with black powder and 'expansion tamping,' with the holes set in line with the rift, and bevel-notched at the mouths of the holes in the same direction to aid in starting the break, the rock may be split off in large monoliths with approximately plane-surfaces, and these again may be cut up into smaller blocks by blasting similarly along the 'grain.' In such work the shots must be fired simultaneously by electricity.

The Alaskan coalfield of greatest importance so far discovered, according to the U. S. Geological Survey, is that north of Knik Arm, the most northerly branch of Cook Inlet, including the Matanuska basin. Other mineral wealth is present in the same region, many of the streams containing gold, although it has been discovered only in small quantities up to the present time. The high mountains between Knik and Matanuska rivers are reported to contain copper as well, but the value of the coals of the area overshadows that of the other minerals. Excellent bituminous and semi-bituminous steaming and coking coals, comparing favorably with similar coals from Pennsylvania, occurring in beds ranging in thickness from 2 to 11 ft., underlie at least 70 square miles of the 400 throughout which coal-bearing formations exist. Anthracite coal has also been found in this region, but the quantity is uncertain. Lignitic coals occur in adjacent areas. Accessibility by improved transportation will make these deposits of the highest industrial importance, and railroads now under construction will soon open them up to the world. The U. S. Geological Survey announces the publication of a report on a geological reconnaissance in the Matanuska and Talkeetna basins, made during the summer of 1906 by Sidney Page and Adolph Knopf. The topographic work was in charge of T. G. Gerdine. The geologic report is accompanied by a topographic map on a scale of four miles to the inch, the area represented comprising about 7000 square miles. This map is of particular interest because it covers a part of the route chosen for the inland extension of a railroad which has been planned to connect the Yukon gold district with tidewater. The largest part of the region described in the report is occupied by the Talkeetna mountains, which form an approximately circular mass bounded on the west and north by the wide valley of Susitna river, the most important tributary of Cook Inlet; on the east by the Copper River basin, and on the south by Matanuska valley, from which they rise abruptly. The interior of this mountain mass is an exceedingly rugged area, some of the highest points reaching altitudes of 8000 to 9000 ft., and access to it is possible only along the larger stream systems.

HANDY TRAMWAY.

Written for the MINING AND SCIENTIFIC PRESS
By DONALD F. CAMPBELL.

An engineer often finds it necessary to get a sample of a few tons from an inaccessible prospect for the purpose of making a metallurgical test. The problem often arises whether to pack or sled the ore, and how much should be spent on building a road or a trail. The accompanying notes describe an extemporized aerial tramway employed for bringing down a small tonnage of ore across two creeks and down a precipitous side hill to a wagon road about 600 ft. below. Six tons per hour could be transported by this simple and inexpensive device. The country was well wooded, and a ⅜-in. steel cable was stretched between two big pine trees. At first a large block was attached to a tree at the upper terminal and a ⅜-in. hemp rope taken from the lower terminal and put around the upper terminal and down again. The cable, a ⅜-in. steel guy rope, costing 2c. per ft. was then attached to the end of the hemp rope and unreeled by a horse hauling on the lower end. When this reached the upper terminal the hemp rope was again attached by Crosby clips to the cable farther back and the free end of the cable was then given a twist around the tree to anchor it and again attached to the rope. As it was impossible to get a horse to the upper end, the hemp rope was attached to the cable by Crosby clips at intervals so that it was pulled up on one side and down on the other by the horse, the slack being taken around the trees by hand. When the rope was in position it was tightened at the lower end and twisted around the tree to anchor it. The tightening of the cable was accomplished by attaching a rope to the span with clips, and tying a block and tackle to this. The horse then pulled, and the slack was taken up, and both ends of the rope tightened in this way. The traveling rope used was a ⅜-in. hemp rope and trolleys as shown in the diagram were made in the blacksmith shop. The cost of material for the whole equipment was $30. The erection took a day for three men and a horse, the work being done in winter with snow on the ground, rain falling, and the creek in flood. Some spare rope was left at the lower end, so that the entire ropeway could be moved to get ore from another deposit on an adjoining hill. The upper terminal consisted of a platform from which the boxes could be filled with ore, either sacked or loose, and the lower terminal was provided with a platform and skids so that when the box arrived there was but little jar. The rate of travel could be adjusted by varying the load, and it was found that by sending 400 lb. per trip, the box would just stop at the bottom on the skids without any brake.



A Handy Tramway.

Peat Briquettes.—Word comes from the City of Mexico that an American company has undertaken the manufacture of briquettes from peat. The increasing difficulty of supplying the capital city of the Republic with wood from neighboring forests whence its fuel has come since the days of Cortez, has led to this project of utilizing deposits of peat which have long been known to exist in the vicinity. Eighty years ago Humboldt described magnificent forests within reach of the City of Mexico. Today the region supports only a second growth of little value. The change has been brought about by wood cutters and charcoal burners who have stripped the land and left it to reforest itself if it could, or to relapse into waste. Thus neglected, the land could not grow timber to meet the demands upon it, and the woodcutters have little or nothing near to cut. Fortunately, large bogs of peat are within reach. It has never been much used for fuel because the Mexicans never took pains to learn how to burn it.

Carborundum is made by fusing in the intense heat of the electric arc, a mixture of granulated coke, glass sand, salt, and sawdust. The essential reaction takes place between the silica of the sand and the carbon of the coke when a sufficiently high temperature is reached, and the combination of the excess of carbon, with the reduced silicon to form a carbide of silicon, which latter is carborundum.

DYNAMITE.

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES W. MORSE.

As mining costs receive more business-like treatment more attention is directed to the proper use of explosives, but the explosive itself seems to be the last item to attract careful consideration. The nitroglycerine explosives mostly used in metal mines are ordinary dynamite, ammonia dynamite, gelatine dynamite, and ammonia-gelatine dynamite. The strength of these so-called 'powders' is rated according to the results obtained when fired in the testing mortar, ordinary nitro-glycerine dynamite being used as the standard. This test does not give a true comparison of the relative quickness of the explosives. In the above list the first is the quickest, and the last the slowest. For example, ordinary nitro-glycerine dynamite, because of its quickness, is the most useful for 'mud-capping' or 'sand-blasting' (when boulders are broken by placing the dynamite on them and simply covering it with a layer of mud or moist sand). Ammonia-gelatine dynamite of equal strength, because of its slower action, is practically worthless for this class of work.

Even among engineers one frequently hears the statement that with gunpowder the force of the explosion is upward, while with dynamite it is downward. This is erroneous. Roughly, explosives are chemical compounds or mixtures which, upon explosion or detonation, break up into large volumes of highly heated gases, and it is the expansion of these gases that does the work. By way of illustration, let us consider the gas to be condensed in a metal capsule instead of in the form of potential energy in unstable chemical equilibrium in the explosive mixture. If the capsule should break open suddenly the conditions reached by the explosion of nitroglycerine would be approximated. If the capsule be punctured with many very small holes so that the gas may escape less rapidly, the conditions attending the explosion of black powder or of grades intermediate between black powder and dynamite, would be approximated, according to the speed with which the gas escaped. The more rapid the escape of the gas, the more sudden and violent the shock received by the support on which the capsule was resting. The inertia of the surrounding air is the important factor. Equal volumes of gas expanding an equal amount will do the same amount of work, but in different times in the two cases. Moreover, they will tend to expand with equal force in all directions. To obtain the best result the mine operator will have to determine which of the four explosives is best suited to his work, and what grade of each is best. The mines where special men do all the important blasting are the ones best prepared to carry on such work. The use of a proper detonator is receiving more attention than formerly. With a good ordinary nitro-glycerine dynamite a XXX cap is ample, but a XXXXX cap should be used with all the other grades of high explosives, and even stronger caps are being made for use with gelatine powders.

The fume from the detonation of dynamite is an important matter. The formulas for gelatine dynamite seem to have been given more careful attention than those of the others, and this powder when fresh and sensitive develops but little objectionable gas. The plastic nature of the explosive, and the greater relative safety in handling it, combined with the absence of much objectionable fume, has made this powder popular. I have used common nitroglycerine dynamite which gave as little objectionable fume as the best gelatine-dynamite, and there seems to be no good reason why this powder should not be made as desirable in this regard as the gelatines. The objectionable gases generated by these explosives may be either nitrogen peroxide (NO_2) or carbon monoxide (CO), or both. An excess of NO_2 may be evolved on account of the ingredients being so proportioned that there is an excess of oxygen present, or by the detonation not being perfect. Incomplete or imperfect detonation may happen if the powder has become insensitive, if it is not properly thawed, if it should take fire from the fuse before it detonates, or if too weak a detonator is used. Nitrogen peroxide is poisonous, it makes its presence known by its odor, and by irritation of the eyes and the membranes of the throat and lungs. Carbon monoxide is produced generally when there is a deficiency of oxygen. This gas is odorless. The first evidence of its presence is in the dizziness and staggering produced. When thus warned the individual is often powerless to save himself, though conscious of the danger. This gas is not generated in dangerous quantities by any of the explosives named above, if detonated under proper conditions. The amount of smoke from the fuse is often overlooked in considering the quantity developed by the powder. If fifty feet of fuse should be cut in short lengths and burned in the face of a drift it would make it a disagreeable place in which to remain. After some blasts there is good reason to believe that undecomposed nitro-glycerine remains volatilized in the air, and to this is due in great part the so-called 'powder headache.' When an objectionable powder is used, even though the drift is ventilated thoroughly, there will be enough gas held in the air-space of the broken ore to be disagreeably felt by the shoveler. When the miners are brought out of a mine, overcome by gas, their comrades often throw cold water over them, or strike or kick them 'to make them fight.' As a matter of fact, the system has already received as severe a shock as it can stand. The patient should be kept quiet and warm, and a physician summoned: the face and neck may be bathed with cold water, and a little stimulant administered. 'First aid to the injured' outfits should be kept at all mines and instructions posted so that all may become familiar with them. The average miner is liable to let a man die from inattention, or to kill him by doing the wrong things with the best intentions.

Black sands comprise the minute particles of the heavy, hard, and resistant minerals originally existing in the rocks that form the various gravel deposits of California, as well as of any other country where metamorphic and igneous rocks exist or predominate.

GOLD PLACERS OF SEWARD PENINSULA.

No more striking example of the rapid industrial changes that may be wrought in an isolated province by the exploitation of rich gold placers could be cited than that which is afforded by the history of the large peninsula thrust out from the northwestern coast of Alaska, dividing the Bering sea from the Polar sea. In Bulletin No. 328, soon to be issued by the U. S. Geological Survey, Alfred H. Brooks, in charge of the division of Alaskan mineral resources, says:

"A decade ago Seward Peninsula was little more than a barren waste, unpeopled except for a few hundred Eskimos and a score of white men: now it is the scene of intense commercial activity, supporting a permanent population of 3000 or 4000 people, which in summer is more than doubled. A decade ago the only communication with the civilized world was through the annual visit of the Arctic whaling fleet and the revenue cutter; now a score of ocean liners ply between Nome and Puget sound during the summer months, and even in winter a weekly mail service is maintained by dog teams. Railways connecting some of the inland mining centres with tidewater traverse regions which a few years ago were almost unknown to white men. This industrial improvement is the result of the discovery and exploitation of the gold deposits."

Map of Seward Peninsula.

As there has been but one successful attempt at auriferous lode mining in this region, practically all the gold production — approximately $37,000,000 in the nine years from 1898 to 1907—has been taken from the placers, and it is the geologic and industrial history of these placers which is discussed in this report.

Compared with the output of the California placers, which are estimated to have yielded in two years (1851 to 1853) $62,000,000, and of the Klondike placers, whose output in the first decade is valued at $118,000,000, the production of the Seward Peninsula placer mines is small. A rough outline map in Mr. Brooke's report illustrates approximately the relative size of the gold-bearing areas of the three regions, and his comparison is most interesting.
